tage of simplicity; but its advocates have never been able to show any real foundation for it. [DIVINE RIGHT; NON-RESISTANCE.] The second class bases society on the abstract rights of man, attributes all power to the people, and considers no government legitimate except such as is founded on their consent. This theory also is plain and clear in the abstract; but has the defect of becoming impossible in application. For, 1. The principle of the *social contract*, or implied consent of the people, is a mere philosophical fiction; 2. The actual consent of the people (i.e. the majority of it) to any existing form of government has never been satisfactorily ascertained. This was notoriously the case in every European country, until at least the singular experiments made of late years in France under the name of universal suffrage. And even the representative government of the United States of America is chosen by a constituency from which slaves, women, and persons under twenty-one years of age (that is, in all, five-sixths of the population) are excluded. Now the exclusion of any one of these classes can only be justified on grounds of expediency; and similar grounds might equally justify the adoption of other tests (e.g. that of property, as in England), which would still further reduce the number of the constituency; 3. Supposing a government established by the actual voices of a majority of the whole people, the question would still arise, whether every subsequent act of that government was legitimatised by that original validity. This question was much debated in France at the period of the trial of Louis XVI.; when the Convention, elected by a majority of the people, was assuming the extraordinary power of judging that monarch. The Girondins on that occasion contended that an appeal to the people (i.e. to the suffrages of a majority of the constituents) was necessary in order to ratify the act; and in a greater or less degree it must always arise, whenever an alteration in circumstances since the period of the election of the representative body has called for the adoption of extraordinary measures. Between these two classes of theoretical politicians, the greater number are content to hold that the only fundamental principle of government is expediency, and its only right that given by municipal law or peaceable possession. In their view all government is equally legitimate so soon as it is fairly established; while they fully admit that a question, and often a very difficult one, arises on every violent change of institutions, as to how soon the new government *de facto* has acquired the character of legitimacy. In the language of modern politics this word has acquired a peculiar sense, chiefly from its employment about the period of the congress of Vienna, when the old hereditary dynasties were termed legitimate in contradistinction to those which the French revolution and the subsequent wars had founded. Hence the principle of legitimacy has been, very incorrectly, opposed

LEGITIMATION

to that of representative or popular government; a mere abuse of terms, but an important one, from the powerful effect which words are able to produce in political discussion.

Legitimation. The act by which natural children are rendered legitimate. By the jurisprudence of countries under the Roman or civil law, subsequent marriage of the parents legitimatises bastard issue.

Legumen (Lat.). In Botany, a one-celled, one or many seeded, two-valved, superior fruit, dehiscing by a suture along both its face and its back, and bearing its seeds on the ventral suture only. It differs from the follicle only in dehiscing by two valves. Sometimes it is indehiscent, as in *Cassia fistula*, &c.; but the line of dehiscence is in such species indicated by the presence of sutures.

Legumina. *Vegetable cascin.* An albuminoid matter existing in leguminous plants. It is an important flesh-forming constituent of peas, beans, and other leguminous or *pod* vegetables.

Leguminosae. A very extensive natural order of polypetalous Exogenous plants belonging to Lindley's Rosal alliance. They are found in all parts of the world, forming large trees and huge twiners in the tropics, and being herbaceous plants or small bushes, rarely trees, in colder countries. The order contains a great variety of useful and beautiful species, some of which, like Clover, Lucern, Saintfoin, and Vetches, are cultivated for cattle; others, as Peas, Beans, Lentils, and various other kinds of pulse, form part of the food of man. Indigo, Logwood, and many others are well-known dyeing plants. Several *Acacias* produce gum arabic. Certain *Astragali* yield tragacanth. The Tamarind and others bear pods whose interior is filled with an agreeable fecula or pulp; *Cassia acutifolia* and others yield Senna; *Glycyrrhiza* the Liquorice root; *Ceratonia* is the wild Locust Fruit of Scripture. Finally, many are valuable tonics, and some are poisonous, among which is the common LABURNUM (which see). The larger part of this order consists of plants called Papilionaceous, from a fancied resemblance between their flowers and a butterfly. Such plants have one large expanded petal, and four others much smaller, which form also and carina in front of the vexillum; but in others the more usual form of corolla is observed, and there are even some which, like *Ceratonia*, are apetalous. The division of the order called *Mimosae* is remarkable for having very small flowers with long stamens, and growing in balls or spikes.

Lehrbachite. A native selenide of mercury and lead (probably a mechanical mixture of the two selenides), occurring at Lehrbach in the Harz.

Lehnulite. A compact variety of Natrolite, found at Glenarm in Antrim, by Captain Lehnul, after whom it was named.

Leibnitz's Theorem. In the Differential Calculus, a theorem concerning the successive differentiation of a product of two functions.

LEMNISCATA OF BERNOULLI

It is most easily remembered in its symbolical form. If by D_u we denote the operation $\frac{d}{dx}$ applied exclusively to u , and by D_v the same operation applied exclusively to v , we have, obviously,

$$\frac{d(uv)}{dx} = v \frac{du}{dx} + u \frac{dv}{dx} = (D_u + D_v) uv,$$

and generally,

$$\frac{d^n(uv)}{dx^n} = (D_u + D_v)^n uv = v \frac{d^n u}{dx^n} + n \frac{d^{n-1} u}{dx^{n-1}} \frac{dv}{dx} + \frac{n(n-1)}{1.2} \frac{d^{n-2} u}{dx^{n-2}} \frac{d^2 v}{dx^2} + \&c. \dots + u \frac{d^n v}{dx^n},$$

which is the theorem in question.

Lemanite. A synonym of Saussurite, after Lake Leman, in the neighbourhood of which it is found.

Lemna (Gr. *λῆμμα*, anything taken). In Geometry, a preliminary proposition, laid down for the purpose of facilitating or rendering more perspicuous the demonstration of a theorem or the construction of a problem.

Lemming. A name given to a species of clavicate Rodents (*Hypodæus Lemmus*, Ill.) very abundant in the north of Europe on the shores of the Arctic Ocean. It is as large as a rat, and is remarkable for its occasional migrations in innumerable bodies. At these periods the lemmings are said to march in a straight line, regardless of rivers and mountains; and, unimpeded by any obstacle, they devastate the country over which they pass. [MIGRATION.]

Lemna (Gr.). The Duckweed genus, a curious family of plants, consisting of small, usually round shield-like bodies floating on water, and forming the 'green mantle of the standing pool.' They belong to the *Pistiaceae*, are of very singular structure, and well worth examination.

Lemnian Earth. A clayey substance found in the island of Stalimene (Lemnos), and used as a medicine in Turkey. It was formerly dug up once a year with much solemnity, and stamped with an official seal. [TERRA SIGILLATA.]

Lemniscata of Bernoulli. A curve of the fourth order having the form of the figure 8. Its polar equation is

$$r^2 = a^2 \cos 2\theta,$$

a particular case, therefore, of the more general equation

$$r = a \cos^{\frac{1}{n}} \theta,$$

which represents a family of curves of which each individual has for its inverse, its reciprocal, and its pedals a curve of the same family.

[PEDAL.] The constant a in these curves indicates the constant ratio of the segments into which any radius vector is divided by projecting upon it, orthogonally, the corresponding centre of curvature. The equations of the inverse, the reciprocal, and the n^{th} pedal of

$$r = a \cos^{\frac{1}{n}} \theta$$

LEMON

are obtained, respectively, by changing ϵ into $-\epsilon$, $-(1+\epsilon)$, and $\pi+\epsilon$. In the case of the lemniscata $\epsilon=\frac{1}{2}$, its first negative pedal, therefore, has the equation

$$r=a\cos\frac{1}{2}2\theta$$

or

$$r^2\cos 2\theta=a^2,$$

which is well known to be that of an equilateral hyperbola; so that the lemniscata is the first positive central pedal of the equilateral hyperbola. The properties of the above family of curves have been investigated by W. Roberts (*Liouville's Journal*, vols. x. xii. xv.), by Prof. Hirst (*Annali di Matematici*, 1859), and by several others. The entire arc S of any such curve being known, as well as that of its pedal S_1 , those of all other pedals can be found by means of the simple and remarkable relation

$$\frac{S_n}{S_{n+2}} = \frac{e_{n+1}}{e_{n+3}},$$

from which latter can be deduced the equally interesting relation

$$\frac{S_n S_{n+1}}{e_{n+1}} = 2\pi a^2,$$

which holds for all values of n for which $e_n=n+\epsilon$ is positive.

The arcs of the lemniscata can be added, multiplied, or divided algebraically. On this subject the reader may be referred, however, to Legendre's *Exercices de Calcul Integral*, t. i., and to a memoir by Serret in *Liouville's Journal*, t. x.

The integral

$$s = \int \frac{dr}{\sqrt{1-r^4}},$$

which expresses the length of a lemniscate arc, is called a *lemniscate integral*; its inverse r considered as a function of s is called a *lemniscate function*. These functions play an important part in the theory of numbers; they bear the same relation to the theory of complex numbers as that which circular functions have to that of ordinary real numbers.

Lemon (Ind. leemoo). The fruit of the *Citrus Limonum*. [CITRUS.]

Lemons, Essential Oil of. A liquid contained in the cells of lemon peel. It may be collected by pressing a quantity of the peel. Its chief constituent is a fragrant hydrocarbon isomeric with oil of turpentine. When used by confectioners, it forms a disagreeable substitute for the fresh peel.

Lemons, Essential Salt of. The bin-oxalate of potash is often sold under this name; it is chiefly used for removing iron-moulds and ink-stains from linen.

Lemur (Lat. lemur, a ghost). This term was applied in the Linnaean system to several of the lower Quadrumanous animals of different structure and habits; it is now restricted to those which have the inferior incisors long, compressed, straight, and sloping forwards, and the lower canines approximated, and of similar form and direction, differing only

LENS

in a slight increase of size, whence they are usually been enumerated as incisors: the upper incisors are straight, and the intermediate ones are separated from each other. The long pointed canines of the upper jaw are principally opposed to the trenchant anterior false molars below. Each of the four extremities is provided with an opposable thumb; but the index digit of the hinder hand has its nail developed into a long, curved, sharp-pointed claw. The use of this claw is to clean or dislodge vermin from the long and thick woolly hair. The lemurs deviate from the typical Quadrumanous, and approximate to the ordinary quadruped in their elongated pointed head and sharp projecting muzzle; the posterior limbs are a little longer than the anterior; the tail is long, thick, and bushy. They are all natives of Madagascar and of some of the smaller islands in its neighbourhood. To judge from the nature of their covering, it might be supposed that the lemurs were natives of a cold climate; but their fur has relation to the season of their activity. They sleep by day, and move about in the night season, during which time the air is often sufficiently cold in the tropical latitudes. Their nutriment is a mixed diet of fruits, insects, and small birds; the latter they surprise while at roost.

Lemures (Lat.). In Mythology, spirits of the dead which in the belief of the Romans were able to hurt the living. Hence it was necessary to propitiate them; and this was done specially at the Lemuria, which recurred yearly in the month of May.

Lemuridae. The family of Quadrumanous Mammals of which the genus *Lemur* is the type. [STREPSIRHINA.]

Lengthening Pieces. In Shipbuilding, the portions of each rib, above the top timbers, which are laid on to impart the necessary height to the sides of the vessel.

Lenitive Electuary. The ingredients of this preparation are senna leaves, the pulp of figs, tamarind, cassia, and prunes, corianderseed, liquorice root, and refined sugar. When properly made it is an elegant preparation, but (says Dr. Paris) the directions of the *Pharmacopœia* are rarely followed; the great bulk of it sold in London is little else than prunes, figs, and 'jalap.' (*Pharmacologia*.)

Lens. In Optics, a thin piece of glass or any other transparent substance, bounded on both sides by polished spherical surfaces, or on the one side by a spherical and on the other by a plane surface; and having this property, that parallel rays of light in passing through it have their direction changed, so as to converge to a given point called the *principal focus* of the lens, or to diverge as if they proceeded from that point.

Lenses receive different denominations according to their different forms. Thus,

LENS

A *spherical lens*, shown at A, is a sphere or globe of glass.

A *double convex lens*, shown at B, is a solid formed by two convex spherical surfaces; and is *equally convex* or *unequally convex*, according as the radii of its two surfaces are equal or unequal.

A *plano-convex lens*, C, is that of which one of the surfaces is *plane*, and the other *convex*.

A *double concave lens*, D, is bounded by two concave spherical surfaces, which may have either the same or a different curvature.

A *plano-concave lens*, E, has one surface *plane* and the other *concave*.

A *meniscus*, F (so called from its resemblance to a little moon, Gr. *μηνίσκος*), is a lens of which one of the surfaces is *convex* and the other *concave*, and which meet if continued. The radius of the convex surface is consequently smaller than the radius of the concave.

A *convexo-concave lens*, G, is that of which one of the surfaces is *convex* and the other *convex*; but in this case the surfaces will not meet though continued, the radius of the concave surface being smaller than that of the convex one.

The straight line MN which passes through the centres of all the curved surfaces, or is perpendicular to both surfaces of the same lens, is called the *axis* of the lens; and it is in this line that the focus of the lens is situated.

It was observed, at an early period, that a transparent body of a spherical form had the property of collecting at the focus the parallel rays of light which fall on its surface. But it was remarked, at the same time, that the illumination at these foci was extremely feeble, in consequence of the thickness of the glass through which the light had to pass. This inconvenience is removed by taking only two small segments instead of the entire sphere; by which means, as the refraction takes place only at the surfaces, and not in the interior of the glass, the very same refraction of the rays is produced as when the whole sphere is used; and the thickness of the glass being greatly diminished, the rays pass through it in much greater number, and the intensity of the light in the focus is much more considerable.

The rules for finding the focal distances of the different sorts of lenses are the following. They depend in some measure on the refracting power of the glass. We shall here suppose the index of refraction to be 1.500.

1. Rays of light, R L, R L, falling on a convex lens in directions parallel to the axis, are refracted to the point F, which is called the principal focus. In a *double* and *equally* convex lens the distance of F from C, the centre of the lens, is equal to the radius of the spherical surface. If the lens is *plano-convex*, the focal distance is equal to twice the radius of the spherical surface. If the lens is *unequally* convex, its focal distance is found by this rule: Multiply the

two radii of its surfaces, and divide twice that product by the sum of the radii; the quotient will be the focal distance required.

2. When the rays fall on a convex lens, whose principal focus is F, converge towards a point O, their convergence will be hastened, and they will be refracted to a point O', which is nearer the lens than the focus F. The two points O and O' are conjugate foci; and they are related in such a manner that C O' is a fourth proportional to C O + C F, C O and C F. Hence, when the point O is given, the conjugate focus O' will be found by this rule: Multiply the principal focal distance C F by C O, and divide the product by the sum of those numbers. It is obvious that as the distance of O becomes greater, O' approaches to F, and when O is at an infinite distance O' coincides with F.

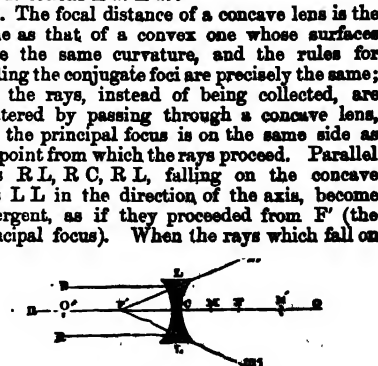

3. Suppose diverging rays issuing from a point O to fall on a double convex lens of which the principal focus is F. In this case they will be refracted to a point O'; and the conjugate foci O and O' are so related that C O' is a fourth

proportional to C O - C F, C O and C F. Hence O' is found by the following rule: Multiply the principal focal distance C F by C O, and divide the product by the difference between C O and C F. As the point of divergence O recedes from the lens, the point O' approaches nearer to F; and when O is at an infinite distance O' coincides with F. As O approaches the lens, O' recedes from it; when O is at F' (the focal distance) the refracted rays become parallel to the axis; and when O is between F' and C, as at M, the refracted rays diverge in the directions L m L m'.

4. The focal distance of a concave lens is the same as that of a convex one whose surfaces have the same curvature, and the rules for finding the conjugate foci are precisely the same; but the rays, instead of being collected, are scattered by passing through a concave lens, and the principal focus is on the same side as the point from which the rays proceed. Parallel rays R L, R C, R L, falling on the concave lens L L in the direction of the axis, become divergent, as if they proceeded from F' (the principal focus). When the rays which fall on

a concave lens converge towards the point F, they are refracted in the direction parallel to

LENS-SHAPED

the axis. When the incident rays converge to a point O beyond F, the refracted rays diverge as if they proceeded from a conjugate point O' also farther from the lens than F'; and when the incident rays converge towards a point M, between C and F, the refracted rays will be convergent, and meet in a conjugate point M' on the same side of the lens with M. These conjugate foci are determined by the rules which have been given for convex lenses. Lastly, when the incident rays diverge from a point O', farther from the lens than the principal focus, the refracted rays will be more divergent, and proceed as if they emanated from a point between the principal focus and the lens. The rule is, in this case, also the same as for convex lenses.

5. The effect of a meniscus is the same as that of a convex lens of the same focal distance; and that of a concavo-convex lens the same as that of a concave lens of the same focal distance. The principal focal distance is found by this rule: Divide twice the product of the two radii by the difference of the radii.

In deducing the above rules it has been assumed that the focus into which the rays are refracted is a mathematical point; but this is not strictly true, unless the rays only fall on the lens very near its centre, by reason of the spherical aberration. [ABERRATION.] For the correction of the chromatic aberration, arising from the unequal refrangibility of the luminous rays, see ACHROMATISM. [LIGHT; OPTICS; REFRACTION.]

Lens-shaped, Lenticular, or Lenticiform. In Botany, a term used in describing the general figure of bodies, to denote their resembling a double convex lens.

Lent. A solemn time of fasting in the Christian church; so called from the A.-Sax. *lencten*, Ger. *lenz*, *spring*. The term of Lent comprises the period of six weeks and four days from Ash-Wednesday to Easter; but the six intervening Sundays being omitted, it is reduced to exactly forty days; the time assigned for the fast which preceded the temptation of Christ in the wilderness. [EASTER.]

Lento or Lento (Ital.). In Music, a direction to the performer that the music to which the word is prefixed is to be performed slowly. [ALLEGRO.]

Lentibulariaceae. A very small natural order of herbaceous Exogens, natives of the marshes and waters of all parts of the world. They are nearly allied to *Scrophulariaceae*, but are distinguished from them by their free central placenta and minute exalbuminous embryo; and from *Primulaceae* by their irregular flowers, their stamens, and their ovary. The beautiful *Pinguicula*, a wild plant in marshes, is one of the genera, and *Utricularia* another. They are of no known use.

Lenticels or Lenticular Glands. In Botany, a term invented by De Candolle to denote certain minute speck-like tubercles on stems. Notwithstanding the importance assigned them by this great botanist, his lenticels

LEPADOGASTER

appear to be nothing more than the points of roots attempting to spring from the surface of bark.

Lentigo (Lat.). A freckle of the skin: so named for its resemblance to a lentil seed.

Lentil (Fr. *lentille*, Lat. *lens*, *lentis*). The seed of a small Leguminous plant, the *Ervum Lens* of botanists. [ERVUM.] The *Revalenta* and *Ervalenta* of the shops are prepared from these seeds.

Lenzinite. A hydrous silicate of alumina, allied to Halloysite. There are two kinds, found at St. Gall in the Eifel (the opaline and the argillaceous), both of which are white, and translucent, and fall into small hard grains when put into water. Named after Lenz, a German mineralogist.

Leo (Lat. *a lion*). One of the zodiacal constellations, situated chiefly on the northern side of the ecliptic. The star *Regulus*, called also *Cor Leonis*, belongs to this constellation.

Leo Minor. The Little Lion: a constellation of the northern hemisphere, between Leo and Ursa Major. This constellation has been formed by the moderns, and is not given in Ptolemy's catalogue.

Leonhardtite. A hydrated silicate of lime and alumina found at Schemnitz in Hungary, and Copper Falls, Lake Superior. It is named after Professor von Leonhard.

Leonine Verses. Latin verses according to the rules of ancient prosody, but rhymed. The name is said to be derived from one of the popes Leo, or, more probably, from a monk called Leoninus. The end rhymes to the middle, i.e. to the two last syllables before the caesura, in hexameters; in pentameters, the two divisions are rhymed. The following distich may serve as an example:—

Demon languebat, monachus tunc esse volebat;
Ast ubi convaleuit, mansit ut ante fuit.

Leopard Wood. The timber of *Brosimum Aubletii*, a South American tree of the order *Artocarpaceae*.

Leopard's Mane. The common name of the genus *Doronicum*, but more especially applied to *D. Pardalianches*.

Lepadites (Gr. *λεπός*, *a limpet*). Goose barnacles; an order of Cirripeds, comprehending those which have a long flexible contractile stem, fixed by its base to some solid body, and supporting at its extremity the principal parts of the animal, enclosed by a multivalve shell or coriaceous case.

Lepadogaster (Gr. *λεπός*, and *γαστήρ*, *stomach*). A genus of Discobolous Malacopterygian fishes, having the following characters: pectoral fins expanded, with stouter rays at their lower edges, which curve slightly forwards, and unite with each other beneath the throat by means of a transverse membrane directed forwards, constituting the boundary of an adhesive disc, close to which there is a second, formed by the union of the ventrals; body smooth, and without scales; head broad and depressed; snout salient and protractile;

LEPALS

branchiæ slightly cleft, and furnished with four or five rays; dorsal fin single, and opposite to the anal, which is near the tail. Of this genus we possess two native species; one of which, called the Cornish sucker (*Lepidogaster cornubiensis*), was discovered by Dr. Borlase on the coast of Cornwall; the other (*Lepidogaster bimaculatus*) has been taken on different parts of the South Weymouth coast. Both species adhere by means of their ventral suckers to rocks, stones, &c., whence the generic name; they feed principally on Crustacea.

Lepals. In Botany, a term invented to denote stamens that are sterile; it is very rarely used.

Lepidine. The name of an oily basic compound (= $C_{10}H_9N$) obtained by distilling quinia or cinchonia with a solution of potash.

Lepidium (Gr. *λεπίδιον*, a small scale). A genus of *Cruciferae* comprising amongst its species *L. sativum*, the Garden Cress, which is extensively grown and mixed with young mustard to form what is called *small-salading*.

Lepidoids (Gr. *λεπίδοειδής*, scaly). A family of extinct fossil fishes belonging to the oolitic formation, remarkable for their large rhomboidal bony scales. Figures of these scales are given in Dr. Buckland's *Bridgewater Treatise*.

Lepidokrokit (Gr. *λεwis*, a scale, and *κρόκος*, saffron). A variety of Brown Iron-ore, occurring at Spring Mills, in Pennsylvania.

Lepidolite (Gr. *λεwis*, and *λίθος*, a stone). Lithia-mica. A mineral of a granular and foliated texture, of a peach-blossom colour. It is a silicate of lithia, alumina, and iron, together with fluoride of potassium. The Lepidolite from Moravia and North America contains the newly discovered metals Cæsium and Rubidium.

Lepidomelane (Gr. *λεwis*, and *μέλας*, black). A variety of Mica occurring in the granite of Three Rock Mountains in Dublin county, and in Sweden.

Lepidoptera (Gr. *λεwis*, and *πτερόν*, a feather). The third order of insects in the system of Linneus, and the tenth in that of Latreille, who has given the following concise and comprehensive description of the characters common to the insects of this most interesting, useful, and beautiful group.

The wings are four, covered on both sides with minute generally coloured scales, resembling farinaceous dust, which are removed by merely coming in contact with the finger. The oral apparatus consists principally of a proboscis, to which the name *antlia* has been given, and which is rolled spirally between two palpi, covered with scales or hairs. This forms the most important part of the mouth, and is the instrument with which these insects extract the nectar from flowers, their only aliment. It is composed of two tubular threads, representing the maxillæ, each bearing near its external base a very small superior palp, in the form of a tubercle. The apparent (inferior) palpi, which form a sort of sheath to the proboscis, replace the labial palpi of the mandibulated

LEPIDOPTERA

insects: they are cylindrical or conical, usually turned up, composed of three joints, and inserted in a fixed labium, which completes that portion of the buccal cavity inferior to the proboscis. Two little and scarcely distinct, corneous, and more or less ciliated pieces, situated, one on each side, on the anterior and superior margin of the front of the head, near the eyes, seem to be vestiges of mandibles. Finally, we observe, and under an equally small proportion, the labrum or upper lip.

The antennæ vary, and are always multi-articulated. Two ocelli are observable in several species, but concealed between the scales. The three segments of which the thorax is usually composed are united in one single body; the first is very short, and the two others are blended together. The scutellum is triangular, but the apex is directed towards the head. The wings are simply veined, and vary in size, figure, and position; in several the inferior ones are plaited longitudinally near the inner margin. At the base of each of the superior wings is a kind of epaulette, prolonged posteriorly, which corresponds to the piece called *tegula* in the Hymenoptera. The abdomen, composed of from six to seven annuli, is attached to the thorax by a very small portion of its diameter, and presents neither sting nor ovipositor. In several females, however, as in *Cossus*, the last rings become narrowed and extended, to form an oviduct resembling a pointed and retractile tail. The tarsi always have five joints. There are never more than two kinds of individuals, males and females.

The females usually deposit their ova, frequently very numerous, on the vegetable surfaces which are to nourish their larvæ, and soon after perish. [BUTTERFLY.]

The larvæ of Lepidopterous insects are well known by the name of *caterpillars*. They have six squamous or hooked feet, which correspond to the legs of the perfect insect, and from four to ten additional membranous ones, or *prolegs*; the two last of which are situated at the posterior extremity of the body. Those caterpillars which have but ten or twelve in all have been called, from their mode of progression, *geometra*. Several of these geometers, when at rest, remain fixed to the branches of plants by the hind feet alone, whence in the form, colour, and directions of their body, they resemble a twig. They can support themselves in this position for a long time without exhibiting the slightest symptom of life. So fatiguing an attitude must require prodigious muscular force; and, in fact, Lyonnet counted 4,041 *muscles* in the caterpillar of the *Cossus ligniperda*, or willow-caterpillar.

The body of these larvæ is generally elongated, almost cylindrical, soft, variously coloured; sometimes naked, and sometimes covered with hairs, tubercles, and spines. It is composed of twelve segments or annuli, exclusive of the head, with nine stigmata on each side. Their head is invested with a corneous

LEPIDOPTUS

or squamous dermis, and presents on each side six shining granules, which appear to be ocelli; and it is furnished with two very short and conical antennae, and a mouth composed of strong mandibles, two maxillae, a labrum, and four small palpi. The silk which they spin is elaborated in two long and tortuous internal vessels, of which the attenuated superior extremities terminate in the tip. A tubular and conical mamilla forms the spinneret through which the threads are spun.

Most caterpillars feed on the leaves of plants; some gnaw their flowers, roots, buds, and seeds; others attack the ligneous or hardest part of trees, softening it by means of a fluid which they disgorge. Certain species attack our woollens and furs, thereby doing us much injury; even our leather, bones, wax, and hair, are not spared by them. Several confine themselves exclusively to a single article of diet; others are less delicate, and devour all sorts of organised matters.

Some of them form societies, and frequently live under a silken tent, spun by them in common, which even shelters them in winter. Several construct sheaths for themselves, either fixed or portable; others make their abode in the parenchyma of leaves, where they form galleries. The greater number are diurnal; the others never issue forth but at night. The severity of winter, so fatal to almost all insects, does not affect certain *Phalaena*, which only appear in that season.

Caterpillars usually change their skin four times previously to passing into the state of a nymph or chrysalis. Most of them spin a cocoon in which they enclose themselves. A frequently reddish liquor, which Lepidopterous insects eject at the moment of their metamorphosis, softens or weakens the extremity of the cocoon, and facilitates their exit; one of these extremities, also, is generally thicker than the other, or presents a favourable issue by the peculiar disposition of the fibres. Other caterpillars are contented with connecting leaves, particles of earth, or of the substances on which they have lived, and thus forming a rude cocoon. The nymphs of the diurnal Lepidoptera reflect a metallic lustre, and are ornamented with golden spots, whence the term *chrysalis* applied to them; they are naked, and fixed by the posterior extremity of the body. The nymphs of all the Lepidoptera are swathed or resemble mummies. These of several insects at this order, particularly of the *Diurna*, undergo their metamorphosis in a few days; they even frequently produce two generations in the course of the year. The caterpillars or chrysalides of others, however, remain during the winter in one of these states, and undergo their final transformation in the ensuing spring. The Lepidoptera issue from their nymphal envelope through a slit, which is effected in the back of the thorax.

Lepidoptus (Gr. *Lepis*, a scale, and *ptus*, a foot). A genus of Tenebrionidae, characterized by the reduction of the ventral line to the condition

LEPROSY

of small scaly plates. The thin and elongated body is without scales: it is furnished with a dorsal fin, which extends its whole length, and a narrow anal fin; it terminates in a well-formed caudal. The branchiostegal rays are eight in number; the head is pointed, with a single row of lunate teeth in each jaw, the largest above, and others, very small, on the palatine and pharyngeal bones. Of this genus one native species is known, called the Scabbard-fish (*Lepidopus argyreus*). It is very rare: only four examples are recorded by Mr. Yarrell, which were taken on the southern shores.

Lepidosteus (Lævis, and *border*, bone). The bony pike of the fresh waters of North America. It is analogous to the Ganoid scaled fishes which existed in great numbers during the Palaeozoic period. Its scales are hard, bony, rhombic, and arranged in oblique rows, descending backwards from the dorsal towards the ventral side.

Lepidotea. In Botany, scurfy, or covered with membranous scales.

Lepidotus (Gr. *lewis*). In Palaeontology, the name of a fossil fish, distinguished by its large thick rhomboidal enamelled scales, and its hemispherical or obtusely conical teeth: its remains are widely diffused through the Wealden formation.

Lepus (Gr. *a scale*). In Botany, a scale or scurf, consisting of a thin transparent membrane attached by its middle, and having a lacerated irregular margin, owing to the imperfect union, towards its circumference, of the cellular tissue of which it is composed. Hence the adjective *lepidote*.

Lepisma (Gr. *a scale* or *husk*). A Linnean genus of Apteroous insects, forming the first family of Thysanuroous insects in the system of Latreille. The body of these apterans is elongated, and covered with small scales, frequently silvery and brilliant; from which circumstance the most common species has been compared to a little fish. The antennae are setaceous, and usually very long. The feet are short, and frequently have very large and strongly compressed coxae, resembling scales. These insects run with great velocity: some of them, by means of their caudal appendage, are enabled to leap. Several species conceal themselves in the cracks of the framework of windows, in wardrobes, under damp boards, &c.; others hide beneath stones.

Lewisia. In Botany, a term sometimes applied to the cup-shaped disc of *Peonia* and *Aconitum*; but seldom employed.

Lepismidae. The family of Thysanuroous insects of which the genus *Lepisma* is the type. It includes the genera *Lepisma* proper and *Machilis*.

Lepistite (Gr. *Levis*, a scale, and *litos*, stone). A variety of Anorthite from Sweden.

Leporidae. The hare tribe, or the family of Rodents of which the genus *Lepus* is the type.

Leprosy (Gr. *lepra*). This disease, if we are to understand the term as expressing the

leprosy of Scripture and of the old writers, of elephantiasis.

gracorum), and in all probability is hereditary, but not contagious. It begins generally in the tubercular form, the parts affected often becoming void of sensation. The features become distorted by deep thickening of the cellular tissue; while the skin gets corrugated, thickened, and deeply furrowed. Internal and deeper parts next become affected, and even the bones partake in the disease. These changes sometimes proceed rather rapidly, but in most cases many years of life are allowed, the disease making but very slow progress, or even for a time remaining stationary. The cause of the leprosy is at present unknown; some attributing it to the ingestion of diseased or putrid fish, while others speak of bad ventilation and dirt as having much to do with its causation. The disease still exists in the East and West Indies, in the Levant, and in Sweden and Norway, but it rarely occurs in England except in a very mitigated form. Nothing is known to cure this horrible malady, or even to afford relief by stopping its progress.

Leptospermum (Gr. *λεπτόσπερμος*, with thin seed). A genus of *Myrtaceæ* which yields the Tea-tree of Tasmania and Australia. The species is *L. lanigerum*.

Leptura (Gr. *λεπτός*, slender; *ὄψιδ*, a tail). A Linnæan genus of Longicorn beetles, now the type of an extensive family (*Lepturidæ*), in which the eyes are rounded and entire, or, if slightly emarginate, with the antennæ inserted before the emargination. The head is always inclined posteriorly behind the eyes, or is abruptly contracted at its junction with the thorax, in the manner of a neck: the thorax is conical or trapezoidal, narrowed anteriorly; the elytra become gradually narrower. The term *Leptura* is now restricted to those Lepturidans in which the head is abruptly narrowed immediately behind the eyes; the antennæ inserted near the anterior extremity of the internal emargination of the eyes, the two eminences from which they rise being almost confounded in one plane. The thorax is almost always smooth, or without lateral tubercles.

Lepurandra. A genus of *Artocarpaceæ* now frequently referred to *Antiaris*. [*ANTIARIS*.] *L. saccidora* is the Sack-tree of the West Indies. The tough fibrous bark is ingeniously constructed into sacks in the following manner. A tree of proper diameter is chosen, and cut intounks of the length which is required for the sacks; theseunks are soaked for a short time, and then beaten with clubs, until the outer bark is removed and the inner loosened, when it is turned inside out, and either sewn up at bottom or a piece of wood left attached.

Lepus (Lat. a hare). A genus of Rodents peculiarly distinguished by having their superior incisors double; i.e. each of them has a smaller one behind it. The molar teeth are also more numerous than in most other Rodentia, there being six on each side of the upper jaw,

and five on each side of the lower jaw: the ears are very long, the tail short and turned up. The species of this genus are called *hares* and *rabbits*. The eyes are large and prominent, and, with the well-developed ears, serve to announce to these timid and defenceless animals remote objects and sounds of peril: the strength and proportions of the limbs, of which the hind pair is much longer than the fore, enable them to escape by rapid flight. The smaller species, as the rabbit, add to their means of safety by burrowing in the soil. Among the anatomical characters of the genus *Lepus* may be reckoned the rudimental condition of the clavicles, and the reticulate bony structure of the infra-orbital spaces.

Lepus. The Hare. In Astronomy, one of the forty-eight ancient constellations of Ptolemy, situated in the southern hemisphere.

Lernæa (Lat. *Lernæus*, an epithet for a snake, from the dragon of Lerna). A Linnæan genus of low-organised crustaceous animals, all of which are external parasites of fishes, and constitute the class *Episœa* of modern systems.

Lernæiformes. The name of a family of Siphonostomous Crustaceans, comprehending those with a long vermiform body.

Lessons (Fr. *leçon*, Lat. *lectio*). Certain portions of the Scriptures read in most Christian churches during divine service. The performance of this duty in the ancient church devolved on the catechumen. In the English church, the greater part of the Old Testament is read once through in daily lessons; and the New Testament, with the exception of Revelations, thrice in the year.

In the Presbyterian church the word *lesson*, in this sense, is unknown; the selection of the passage to be read being left to the choice of the officiating clergyman.

Lestris (Gr. *ληστρίς*, a plunderer, strictly applied to a pirate ship). A subgenus of Gulls, separated from the *Larus* proper on account of their large membranous nostrils opening nearer the point and edge of the beak, and their tail being pointed. They pursue the small gulls with singular pertinacity and boldness to rob them of their food; hence their name.

Lethargy (Gr. *ληθάργία*). A heavy unnatural slumber; sometimes bordering upon apoplexy, from which persons are not easily roused. It sometimes arises from a plethoric state of habit, in which case it requires depletion, but it often also is a symptom of over-fatigue of mind, and then nerve stimulants are indicated.

Lethe (Gr.). In Greek Mythology, the River of Oblivion: one of the streams of the infernal regions. Its waters possessed the quality of causing those who drank them to forget the whole of their former existence. (Virgil's *Æneid* vi.) The word recurs in the names *Leto*; *Latona*, *Lethum*, &c. [*APOLLO*.]

Letter (Fr. *lettre*, Lat. *littera*). A character used to express one of the simple sounds of the voice. Letters properly combined form the visible signs of those sounds by which wo

LETTER

communicate our ideas. For some remarks on the origin of letters, see ALPHABET.

Letters are distinguished by grammarians into vowels and consonants (which latter are again subdivided into mutes and liquids) and diphthongs, according to the organ employed in their pronunciation.

Letter. In Printing, the usual term for an aggregate quantity of types in a printing office; as when a work is put in hand, and there happens to be a great quantity of type of the proper sort unemployed, it is usual to say 'there is plenty of letter;' and, on the contrary, 'there is a scarcity of letter.'

Letter of Attorney. [POWER OF ATTORNEY.]

Letter of Credit. A letter written by one merchant, correspondent, or banker to another, requesting him to credit the bearer with a certain sum of money. The bearer should be described with as many particulars as possible, lest the letter fall improperly into other hands. Under the name of *circular notes*, letters of credit are a very convenient form for carrying such money as is necessary for defraying the expenses of travelling, and for avoiding the risk and encumbrance of taking specie. These notes are negotiable at the current rate of exchange with the principal continental bankers.

Letter of License. An instrument by which creditors allow to a party who has failed in his trade time for payment of debts and management of affairs.

Letters of Marque. [MARQUE.]

Letters Patent or Letters Overt. In Law, letters of the king, open, but sealed at the foot with the great seal of England, conferring some privilege whereby a party is enabled to do or enjoy that which otherwise he could not. Such are letters patent to make denizens, to protect inventions, &c. [PATENT.]

Lettie. The name for that branch of the Aryan family of languages which includes the old Prussian and the living dialects of Lithuania, Kurland, and Livonia. [LANGUAGE.]

Lettsemitte. A hydrated sulphate of copper and alumina occurring in velvety fibres of a smalt-blue colour at Moldawa in the Bannat. It is a rare mineral, named after Mr. W. G. Lettsom.

Lettuce (Lat. *lactuca*). The garden Lettuce is the produce of *Lactuca sativa*. Lettuces have been arranged in two divisions or groups, namely, *Cabbage Lettuces*, comprising all those which have round leaves, and form a compact depressed head resembling a cabbage; and *Cos Lettuces*, those having firm and crisp upright oblong leaves, folded over one another. The latter are preferred for salads; while the cabbage kinds are preferred for soups. Although containing very little nourishment, lettuces rank with the greatest favourites to be found amongst salad herbs.

Leuchtenbergite. A variety of Chlorite occurring in six-sided pyramids at Slatoust in the Ural.

LEVÉE

Leucaine (Gr. λευκός, *white*). A product of the decomposition of caseine, called also *caseous oxide* = $C_8H_{12}O_2N$. [AROSEPADINA.]

Leucite (Gr. λευκός). A crystallised silicate of alumina and potash, of a grey or white colour, generally opaque, and resembling the Garnet in form. It usually occurs in lava, especially in that of Vesuvius; hence it is also termed *Vesuvian* and *volcanic garnet*. This mineral is remarkable as the one in which Klaproth first discovered that potash was a constituent of the mineral kingdom, and not exclusively belonging to vegetables.

Leucocoryllite (Gr. λευκός; κύριος, *a circle*; and λίθος, *stone*). A synonym for Apophyllite. [ΑΡΟΦΥΛΛΙΤΗ.]

Leucoline (Gr. λευκός). One of the organic bases of coal tar.

Leucolite. [ΛΕΥΚΟΛΙΤΗ.]

Leucoma (Gr. λεύκωμα). A white opacity of the cornea of the eye, arising from inflammation. [GLAUCOMA.]

Leucophane (Gr. λευκοφανής, *appearing white*). A silicate of glucina and lime with fluoride of sodium, found in the syenite of Norway, on a small rocky islet near the mouth of the Langesund fiord.

Leucophlegmatic (Gr. λευκός, and φλεγματικός, from φλέγμα, *phlegm*). A pallid flabby state of body.

Leutrite. An indurated sandy marl (which becomes phosphorescent by friction), from the Leutra, near Jena.

Levant (Ital. *levante*, *rising*). In Geography, a term applied in a general sense to any country situated to the eastward of us, or in the eastern part of any continent or country; but, in a more contracted signification, it is given to that part of the Mediterranean Sea which is bounded by Asia Minor on the north, Syria and Palestine on the east, Egypt and Barca on the south, and by the island of Candia and the rest of the Mediterranean on the west.

Levant Nut. One of the commercial names of the berries of *Anamirta Cocculus*.

Levari Facias (Lat. *cause to be raised*). In Law, a writ of execution directed to the sheriff, whereby he is commanded to levy a sum of money upon the lands and tenements, goods and chattels, of a man who has forfeited his recognisances. It is superseded in practice by the writ of *elegit*, except in cases of outlawry.

Levator Muscles. In Anatomy, those muscles which lift the part to which they are attached.

Levéé (Fr. from lever, Lat. *levare*, *to raise*). The term used in court language for the ceremonial visits which distinguished personages receive in the morning; or, as the word implies, at their *rising*. It is chiefly applied in this country to the stated public occasions on which her majesty receives visits from such of her subjects as are entitled by rank or fortune to the honour. The difference between a *levée* and a *drawing-room* consists in this, that while at the former gentlemen alone appear (with the exception of the chief ladies of the

LEVEE

court), both ladies and gentlemen are admitted to the latter.

Levee. A bank raised by the side of a river to confine the waters in case of inundation from the effects of a sudden freshet or thaw. The banks of the Po, the Loire, the Rhine, and those of the Mississippi are defended in this manner, which has sometimes a tendency to raise the bed of the river above the level of the surrounding country.

Levee en Masse (Fr. literally *a universal rising*). A Military expression for the rising of a whole people to defend their country from invasion. In Germany it is styled *landsturm*, in contradistinction to the *Landwehr* or *Militia* [which see]; and there, as in Spain and the Tyrol, its efforts have often proved instrumental in rescuing the country from foreign invasion.

Level (Ital. *livella*—Lat. *libella*—dim. of *libra*—*a plummet*: the old French *livel*, *liveau*, has been changed into *nivel*, *niveau*). An instrument which shows the direction of a straight line parallel to the plane of the horizon.

The plane of the sensible horizon is indicated in two ways: by the direction of the plummet or plumb-line, to which it is perpendicular; and by the surface of a fluid at rest. Accordingly, levels are formed either by means of the plumb-line, or by the agency of a fluid applied in some particular manner. They all depend upon the same principle, namely the action of terrestrial gravity.

Levels in which the plumb-line forms the essential part are those most usually employed for the common purposes required by bricklayers, masons, carpenters, &c. They are constructed under many different forms; but the general principle is as follows: A frame or board is prepared, having one edge perfectly straight, and a straight line is drawn on the frame at right angles to the straight edge. To some point of this straight line a thread carrying a plummet is attached; consequently, when the frame is placed in such a position that the thread of the plummet, hanging freely, coincides with the straight line, the straight edge of the frame, which is perpendicular to it, must be horizontal. [PLUMMET.]

Spirit Level.—By far the most convenient and also the most accurate level is the spirit level, represented in the annexed figure; 'which is nothing more than a glass tube nearly filled

with a liquid (spirit of wine being now generally used, on account of its mobility and not being liable to freeze), the bubble in which, when the tube is placed horizontally, would rest indifferently in any part if the tube could be made mathematically straight; but that being impossible to execute, and every tube having some slight curvature, if the convex side be placed upwards the bubble will occupy the higher part, as in the figure (where the curvature is purposely exaggerated). Suppose such a tube as A B firmly fastened on a straight bar C D, and marked at *a b*, two points distant

LEVELLING STAVES

by the length of the bubble; then, if the instrument be so placed that the bubble shall occupy this interval, it is clear that C D can have no other than one definite inclination to the horizon; because, were it ever so little moved one way or other, the bubble would shift its place, and run towards the elevated side. Suppose now that we would ascertain whether any given line P Q be horizontal; let the base of the level C D be set upon it, and note the points *a b*, between which the bubble is exactly contained; then turn the level end for end, so that C shall rest on Q, and D on P: if then the bubble continue to occupy the same place

between *a* and *b*, it is evident that P Q can be no otherwise than horizontal; if not, the side towards which the bubble runs is highest, and must be lowered. Astronomical levels are furnished with a divided scale, by which the places of the ends of the bubble can be nicely marked.' (Herschel's *Astronomy*, p. 92.)

With proper care they can be executed, it is said, with such delicacy as to indicate a single second of angular deviation from exact horizontality.

Levellers. In English History, a party which arose in the army of the Long Parliament, about the time when it overruled that assembly, and transferred the king to Hampton Court, in 1647. The levellers professed, what their name implied, a determination to level all ranks, and establish an equality in titles and estates throughout the kingdom. Several of the officers belonging to this party were cashiered in 1649; and, on Cromwell's departure for Ireland in the end of that year, they raised mutinies in various quarters occupied by the army, and were put down by Fairfax with some bloodshed. John Lilburne, one of the chiefs of the faction—of whom it was said that 'if none but he were left alive in the world, John would quarrel with Lilburne'—published in 1649 his *Manifestation from J. Lilburne and others styled Levellers*. (Clarendon, books x. & xii.; Godwin's *History of the Commonwealth*.)

Levelling Staves. Instruments used with the spirit level, for supporting a mark, and showing at the same time its height above the ground. As constructed by Troughton, they consist of three sliding rods of mahogany, each about four feet long, and divided into feet and hundredths. They carry each a circular sliding vane, having at the lower edge a square aperture, one side of which is levelled; and a line on the levelled side denotes the reading of the staff. The face of the vane is made of white holly, with an inlaid lozenge of ebony, forming at once a conspicuous object and one easy of bisection. In levelling, the vane must be moved up or down till the horizontal wire of the telescope bisects the acute angle of the lozenge, as shown in the

A A

LEVER

figure. As the line on the levelled edge at *a* denotes the reading of the staff, a piece equal in length to the distance *ab* is cut off from the bottom of the staff, or, rather, the divisions commence at that number of inches above zero. (Simms's *Treatise on Mathematical Instruments*, 1834.)

Lever (Fr. levier, from Lat. *levare*, to raise). In Mechanics, an inflexible rod movable about a fulcrum or prop, and having forces applied to two or more points in it. The lever is one of the mechanical powers; and, being the simplest of them all, was the first that was attempted to be explained. Its properties are treated of by Aristotle; but the first accurate explanation was given by Archimedes, in his treatise *De Equiponderantibus*.

In treating of the lever, it is convenient to distinguish the forces applied to it by different names. One is usually called the *power*, the other the *weight* or *resistance*.

Levers are commonly divided into three kinds,

Fig. 1.

Fig. 2.

according to the relative positions of the power,

Fig. 3.

the weight, and the fulcrum. In a lever of the first kind (fig. 1), the fulcrum *F* is between the power *P* and the weight *W*. In a lever of the second kind (fig. 2), the weight *W* is between the fulcrum *F* and the power *P*. In a lever of the third kind (fig. 3), the power *P* is between the fulcrum *F* and the weight *W*.

The general principle of the lever is, that, when the power and weight are in equilibrio, they are to each other inversely as their distances from the fulcrum. This property is almost an obvious consequence from the principle of virtual velocities; but it may be deduced from more familiar considerations. Let *AB* be a cylinder or bar of homogeneous matter. If supported from the middle, *O*, the two ends would evidently balance each other, and the pressure at *O* would be the same as if

Fig. 4.

the whole matter of the bar were concentrated in that point. Suppose it to consist of two parts, *AC* and *BC*, these again would be separately supported at their middle points *DE*; or the whole of the matter in *AC* may be conceived to be concentrated at *D*, and the whole of that in *BC* at *E*, and the equilibrium would not be disturbed. Hence the weight of *AC* attached at *D*, and the weight of *BC* attached at *E*, would balance the inflexible line *DE*, if supported at *O*, the centre of the whole bar *AB*. But $OD = AO - AD = \frac{1}{2}AB - \frac{1}{2}AC = \frac{1}{2}BC$; and $OE = OB - EB = \frac{1}{2}AB - \frac{1}{2}CB = \frac{1}{2}AC$; consequently *OD* is to *OE* as *BC* to *AC*; or *OD* is to *OE* as the weight concentrated at *E* to the weight concentrated at *D*. This demonstration is commonly ascribed to Archimedes. (Maclaurin's *Account of Newton's Principia*.)

This proposition shows the advantage obtained by using the lever as a mechanical engine. The arm *PF* (fig. 1) is commonly longer than *WF*, and, consequently, when there is equilibrium, the weight exceeds the power. The proportion in which the weight exceeds the power is called the *mechanical advantage*, or purchase. Suppose *PF* (figs. 1 and 2) = 4 feet, and *WF* = 1 foot; then a power of 1 lb. acting at *P* will overcome a resistance of 4 lbs. at *W*.

Suppose the lever with the weights *P* and *W* to turn round the fulcrum, the two points to which *P* and *W* are attached will describe arcs proportional to the radii *FP*, *FW*; consequently the power *P* is to the weight *W* as the velocity of the weight to the velocity of the power. Therefore in this, as in all mechanical engines, when a small power raises a great weight, the velocity of the power is much greater than the velocity of the weight; and what is gained in force is therefore said to be lost in time.

When the power and the weight do not act on the lever in directions perpendicular to its length, or when the arms of the lever are not in the same straight line, or are bent, then the power and the weight are not to each other reciprocally as the arms of the lever, but as the straight lines drawn from the fulcrum perpendicular to the respective directions in which the power and the weight take effect.

Examples of the application of the lever are of constant occurrence in the mechanical arts. The crowbar, the handspike, the poker, scissors, nippers, pincers, &c. are levers of the first kind; the toothed hammer is only a bent lever of this kind. The second kind includes the chipping knife, nutcrackers, the common door, oars and rudders, the wheelbarrow, &c. To levers of the third kind belong the sheep-shears, the treddle of the turning lathe, tongs, &c.: these have a mechanical disadvantage, but admit of a proportionally wider motion. The bones of animals are generally levers of this sort. The socket of the bone is the fulcrum; a strong muscle attached to it near the socket is the power; and the weight of the limb, with whatever resistance is opposed to its motion, is the weight. A very moderate contraction of the muscle thus gives considerable motion to the limb.

From the principle of the lever is deduced the distribution of pressure in the case of a pole bearing an intermediate weight. If the weight hang from the middle, the carriers will share the burden alike; but if a load is laid over the pole, and a vertical from its centre of gravity divides the length unequally, as will be the case on altering the inclination of the pole (for example, in climbing a hill), then the bearer nearest to whom the vertical falls suffers a greater strain than the other.

Universal Lever is the name given to a machine formed of a combination of the lever with the wheel and axle, the object of which is to give a continued rectilinear motion to a heavy

LEVIATHAN

body by means of the reciprocating motion of the lever. FGH is a straight line, whose centre

Fig. A.

of motion is at G. At the extremity of its shorter arm hang two bars, the former of which has a hook to catch into the teeth of the wheel ACD, while the latter has its end bent in order to slide over the outer parts of those teeth. The axle A has a cord wound round it, to the end of which is attached the weight W. Now suppose the end H of the lever to be raised from H to I, while the other end descends from F to B; the bar FE will then push the tooth E of the wheel to C, while the hook D slides over an equal space on the other side of the wheel. On bringing down again the end of the lever from I to H, the other extremity ascends through BF, and the hook D raises up the left-hand side of the wheel through a space equal to EC. Thus the reciprocating motion of the lever is made to communicate a continued rotatory motion to the wheel, and consequently to lift the weight W suspended from its axle by the cord. The universal lever has long been employed in saw-mills, for the purpose of drawing along the logs to the saw. (Gregory's *Mechanics*, vol. ii.)

Leviathan. The name of a great marine animal in the Book of Job, described in ch. xli. as being covered with close-joined or confluent scales, and having the jaws, or 'doors of the face,' armed with terrible teeth round about. Some naturalists have supposed that the crocodile might be the subject of this description; but the 'breath that kindleth coals' could scarcely be suggested by the respiratory actions of a cold-blooded reptile. The same objection applies to the opinion that the leviathan of Job was the extinct megalosaurus: with this additional difficulty, that the megalosaurus was a terrestrial reptile, as the large medullary cavities of its bones prove; while of the leviathan it is said that 'he maketh the deep to boil like a pot; he maketh the sea like a pot of ointment: he maketh a path to shine after him: one would think the deep to be hoary. Upon earth there is not his like.' These expressions accord well with the violent and impetuous exertions of a huge cetacean in his native element; and the verse, 'Out of his nostrils goeth smoke, as out of a seething-pot or caldron,' figures not inaptly the 'blowing' of a whale. The teeth of either the cachalot or grampus might well be termed *terrible*; and their external epidermic covering, if considered as analogous to the scales of fishes, would have its distinguishing peculiarities correctly defined by the following expressions: 'His scales are his pride, shut up together as with a close seal. One is so near another, that no air can come between them. They are joined one to another, they stick together, they

LEVITES

cannot be sundered.' (Verses 16, 16, 17.) Many persons must have witnessed the phenomena of the luminosity of the sea on our own coasts, where it is usually feeble in comparison with that produced in the warmer latitudes of the Mediterranean, or in the tropics. The phenomena which naturalists and voyagers have described as being produced by the swimming and blowing of the cetaceous animals in a phosphorescent ocean, during the night, might likewise have suggested the description of the fire and sparks that escape from the mouth of the leviathan, and of the shining path which he leaves behind him in the deep.

Levigation (Lat. *levigatio*, from *lavus*, smooth). The process of reducing substances to a state of fine mechanical division, by mixing them, previously powdered, with water or some other fluid, and rubbing the paste upon a hard smooth slab, with the flat face of a stone called the *muller*. The paste is then often stirred into a large vessel of water, where the coarser powder first falls, and the finer remains suspended, and is afterwards collected by pouring it off with the water, and suffering it slowly to subside. In this way, by repeated subsidences, powders of very different degrees of fineness are obtained.

Levirate (Lat. *levir*, Gr. *βαδρ*, brother-in-law). A word used in Ecclesiastical Jurisprudence to designate the Jewish custom whereby the brother of a deceased husband was bound to marry the widow; and, in a secondary sense, the marriage of a man with his sister-in-law generally.

Levites. In Jewish History, the descendants of Levi, one of the twelve sons of Jacob, to whom it is stated that no distinct territory was allotted in the land of Canaan, as to the other tribes, because they were set apart for the ministration of the religious services throughout the country, and had forty cities, situated in various parts of Palestine, peculiarly appropriated to their residence. The Mosaic law commanded the tenth of the vegetable produce of the land, and also of the cattle, to be given to them; of this a tenth was set apart for the priests, whose assistants the Levites were. The priests were to be confined to the family of Aaron, who with Moses his brother were both of the tribe of Levi. The classes of which the Levites were composed, their offices, privileges, &c., are enumerated in Num. iii. iv. viii.; also 1 Chron. xxiii.—xxvi.

On this subject the following conclusions are maintained by several recent writers. The historical books of the Old Testament apparently give no evidence of the actual existence of a privileged and powerful sacerdotal caste before the days of the later kings. In the Book of Judges, only two Levites are mentioned, the one being spoken of as belonging to the family of Judah, and wandering about in great poverty until he is appointed by Micah, an Ephraimite, to keep his idols. The other, who seemingly exercises no priestly function, is noticed only in the narrative

which describes an almost complete destruction of the tribe of Benjamin. In the First Book of Samuel, Eli, and his sons Hophni and Phinehas, who are spoken of as priests, belong apparently to the tribe of Ephraim; and their sacerdotal offices are afterwards discharged by Samuel, who seems also to have been an Ephraimite; and, although Samuel rebukes Saul for presuming to offer sacrifice, it is not on the ground that by so doing he was invading the office of an established priestly order. The right of offering sacrifice and of praying for the people is further exercised by David and Solomon; and even under their successors the Levites have no great power or pre-eminence. The full development of their sacerdotal privileges seems to have followed their return from the Babylonish captivity. (Stanley, *Lectures on the Jewish Church*; Colenso *On the Pentateuch*; Kuenen *On the Pentateuch*.)

Levyne (so called from Levy, the crystallographer). A crystallised mineral found in Ireland, Faroe, and elsewhere, closely allied to the scapolites. It is a hydrated aluminosilicate of lime and soda.

Lewisia (after Capt. M. Lewis). A curious North American Mesembryacean plant, the Bitter-root plant of the Canadians, and the Spatum of the Oregon Indians. It has a fleshy root so retentive of life that specimens have been made to grow after having become dried and apparently dead in the herbarium. Hence the species was called *L. rediviva*. The root is eaten by the Indians.

Lexicology or **Lexicography** (Gr. *λέξις*, a word or phrase, and *λόγος* or *γράφω*). A word used by some writers to express that branch of philology which treats of words alone, independently of their grammatical and rhetorical uses; considering their senses, their composition, and their etymology. [PHILOLOGY.] There are two useful papers in the *Quarterly Review* on Greek lexicography, vols. xxii. xlv.

Lexicon (Gr. *τὸ λεγέειν*, sc. *βιβλίον*, a book of words). A dictionary of words, or vocabulary, originally, and still usually, confined to dictionaries of the Greek or Hebrew tongue. The oldest Greek lexicon is the *Onomasticon*, which was written 180 years before Christ: the oldest Hebrew lexicon belongs to the ninth century. [DICTIONARY.]

Leyden Jar. [ELECTRICITY.]

Lesse Majesty. In Jurisprudence, any crime committed against the sovereign power in a state. The name is derived from the Roman phrase, *crimen lese majestatis*, which denoted a charge brought against a citizen for acts of rebellion, usurpation of office, and general misdemeanours of a political character, which were comprehended under the title of injuries to the 'majesty of the Roman people.' The emperors assigned to all offences against themselves the same criminal character; and offences of *lese majesty* were multiplied under their arbitrary governments.

Lherzellite. An olive-green variety of Sahlite occurring at Lake Lherz in the Pyrenees.

Liability,

[COMPANY.]

Liana. A luxuriant woody climber, like those met with in tropical forests.

Lias (the name *Lias* is supposed to be derived from the appearance of the bed in layers in the quarries where it is worked in the middle of England: the term is adopted by geologists of all countries). A remarkable deposit of calcareous clay met with in many parts of England. It generally retains the same mineral form; it is always characterised by similar fossils; and it is traceable by beds very strongly marked. These, in many parts of Belgium, France, and Germany, strikingly resemble the corresponding deposits in the middle of England. Beds of the same age and even of the same kind with similar fossils exist in India, and contemporaneous deposits are very widely spread.

The position of the lias is well marked. It forms the base of the remarkable calcareous group of the middle secondary period, which under the name of Oolitic or Jurassic series is recognised so widely. It overlies the beds which in England are called the *new red sandstone* series (containing salt), and on the Continent the *Triassic* series. It is, however, quite distinct from either.

The contents of the lias and rocks of the liassic series are very interesting and varied. In the middle of England the bands of calcareous nodules, and even calcareous bands of the rock itself, yield an admirable hydraulic cement on burning. They are largely quarried for this purpose. Where the calcareous element is yet more completely observable, as in the marlstone near Cheltenham, the lias yields a good building stone. On the coast of Yorkshire it contains a large admixture of iron pyrites and bitumen, and sometimes there are beds in it approaching the condition of a poor coal or passing into *jet*. The lias shales at Whitby are very extensively worked for the extraction of *alum* produced by a certain amount of manipulation from the decomposition of these shales. Elsewhere the highly bituminous shales are distilled at a low heat for various mineral oils and paraffine; while in some parts of the world, as in various places near the banks of the Danube in Europe, in Virginia in North America, and probably in India, the lias yields considerable stores of valuable fuel, so nearly resembling the true coal of the coal measures as to show no practical difference.

Everywhere, also, the lias is remarkable for its fossils. In England these include a marvellous assemblage of extinct reptiles, of which the *Ichthyosaurus*, *Plasiosaurus*, *Pterodactyl*, and many others, are familiar. Vast multitudes of fishes' remains and numerous characteristic shells also abound. On the whole, there are few more important or interesting deposits known than this liassic series, wherever and however it is presented for investigation.

LIBATION

Libation (Lat. *libatio*, from *libo*, *I pour*). The solemn pouring of wine and other liquids in the religious ceremonies of antiquity; in Greek *swabew*. The libations were usually of unmixed wine; but were sometimes mingled, as wine, oil, honey, &c., with water. The libation was poured between the horns of victims, on the altar or on the ground. There was also a custom of pouring out a small quantity of wine, by way of libation to the gods, at the commencement of their banquets; and libation for the emperors became common under imperial Rome.

Libavious's Fuming Liquor. Bichloride of tin, obtained by distilling a mixture of one part of tin filings with three of corrosive sublimate. It emits dense white vapours when exposed to air.

Libel (Lat. *libellus*, dim. of *liber*, a book). In Law, this term signifies almost any malicious publication by writing or printing, or by signs, pictures, &c. Whatever tends to render a man odious or ridiculous, or to lower him in the esteem and opinion of the world, is a libel; and may either be made the subject of a civil action for compensation in damages to the individual injured, or, as having a tendency to excite his wrath, and provoke a breach of the peace, may be proceeded against by indictment or criminal information. Where it is sought to make a party responsible in damages for a libellous publication, he may set up the truth of it as an answer to the complaint; for the plaintiff, if really guilty of the misconduct or other thing imputed to him, is not considered to suffer by its disclosure any private injury which can be a legitimate ground of compensation to him; but when the proceeding is by criminal prosecution, the truth is no defence whatever, as being altogether immaterial; for the libellous matter may equally provoke a breach of the peace, whether it be true or false. The court, however, will, in general, before granting a rule for a criminal information, which supercedes the usual practice of a presentment by the grand jury, require the prosecutor to deny on affidavit the truth of the matters charged against him. It will be seen, however, that there is not in any case a legal foundation for the maxim vulgarly ascribed to the law, 'The greater the truth, the greater the libel.' All publications are libels, and criminally punishable as such, which have a tendency to disturb the public peace, the government, the established religion, public morals, or the administration of justice. Before the 32 Geo. III. c. 60 (Fox's Act), on a criminal trial for libel the jury were not allowed to take the whole question into consideration, and return a general verdict of guilty or not guilty; but could only decide upon the fact of publication, and whether the libel meant that which it was alleged in the indictment to mean; the court alone taking upon itself to determine the criminality or innocence of such meaning. Now, however, in libel, as previously in all other criminal cases, it is competent to the jury to apply their

LIBERTAS

judgment to the whole question, and return a general verdict of guilty or not guilty. The Act of 6 & 7 Vict. c. 96, commonly called Lord Campbell's Act, has made various important changes in the law of libel. Under that Act, in a criminal proceeding for libel, the truth of the matters charged may be enquired into, but shall not serve as a defence unless their publication was for the public benefit, and the defendant must in that case show on his pleading the public benefit. In civil actions against proprietors or publishers of newspapers, it may also be pleaded that the insertion was made without malice and without gross negligence, and that they had published, or had offered to publish, a full apology.

LIBEL. In the Spiritual Courts, the original declaration in a civil action is so termed. [LAW, ECCLESIASTICAL.]

Libellulines. A genus of Neuropterous insects, of which the dragon-fly, *Libellula*, is the type. [AGRICULTURE.]

Libber (Lat. *bark*). In Botany, the interior lining of the bark of Exogenous plants. It consists of woody tissue in great quantity, and very thick-sided, intermixed with cellular tissue. It appears to be formed annually, at the same time with the concentric zones of wood, and is intended by nature to convey downwards the secretions elaborated in the bark and leaves. It is the principal seat of laticiferous vessels.

The name *liber* was applied by the Romans to the thin coats or rind of the Egyptian papyrus, on which books were written; and hence it passed into a general name for books. [BOOK.]

LIHER. In Mythology. The name given by the Latins to the Greek Dionysus or Bacchus. But the Latin Liber was originally a distinct god, presiding over the fertility of fields, and worshipped along with Libera or Ceres. The name seems to be connected with *liberare* and *libertas*.

Libber Albus (Lat. *the white book*). An ancient book containing the laws and customs of the city of London. It has recently been printed under the direction of the Master of the Rolls.

Liberal (Lat. *liberalis*). In Politics, a cant name, which has been applied since 1816 to the party in each country which advocates constitutional institutions where they do not exist, or their extension into a more popular character where they do. As a party name, this word was perhaps first adopted in Spain, where the party of the cortes assumed the title of *liberales*, and nicknamed their adversaries by that of *serviles*.

Liberalia (Lat.). A festival, in honour of Liber or Bacchus, during which the Roman youths who had attained the age of seventeen assumed the manly dress, or *toga virilis*.

Libertas (Lat.). In the Mythology of the Romans, the goddess of freedom. By the Greeks she was invoked by the synonymous title Eleutheria. At Rome, her most famous temple, built by T. Gracchus, was situated on

LIBERTINES

the Aventine Mount. She was represented under the figure of a woman, holding in one hand a cap, the symbol of Liberty, and two poniards in the other. In modern times a cap is also used as a symbol of Liberty: thus, in France a red cap formed the badge of the Jacobin Club. In England a blue cap with a white border is used as a symbol of the constitutional freedom of the nation, and Britannia sometimes bears it on the point of her spear.

Libertines (Lat. *libertini*). In Church History, a name given, in England, to the early Anabaptists, about the middle of the sixteenth century. [ANABAPTISTS.]

Libertini. [FREEDMEN.]

Libertus. [FREEDMEN.]

Liberty (Lat. *libertas*). Like many other complex subjects involving problems not all of which can be regarded as definitively solved, liberty may be better defined by determining what it is not, than by attempts to lay down what it is. The distinction between rulers and subjects is obviously incomplete, for the relations of subjects or of the members of a community to each other furnish not less important matter for consideration, and in our own day more particularly force themselves on our attention.

When a state is governed by a ruler not responsible to his subjects, it is clear that there can be no such thing as political liberty; but this absolute authority may be exercised by a monarch who has received his power by inheritance or by a usurper who has set himself above law. Among the former may be classed the kings of Eastern nations; among the latter are to be reckoned those who, like Polycrates, Lygdamis, or Pisistratus, rise to power by repressing or subverting an existing constitution. Both these classes of rulers might be equally despotic, but between them the Greek drew a sharp line of distinction. The former were *Basileis*, kings by right of birth or by choice of the nation, and their subjects owed them an obedience the extent of which was not accurately defined, and which practically had no limits. The latter (however beneficent in practice) were *tyrannoi*, tyrants, whom no one was bound to obey any longer than he could help, and whom every citizen was justified by every means in his power, open or secret, to injure or slay. As they were regarded simply in the light of wild beasts who had broken into a sheepfold, tyrannicide became a duty, and the practice founded on the doctrine received the sanction of public opinion. This distinction is of the greatest importance in Greek history, as explaining the very different language which Greek thinkers applied to such of their enemies as Darius and his son, and to such rulers as the Dionysii of Syracuse.

But in Greece the idea of a more extended liberty was early developed. At Sparta, where the highest titular office was filled by two kings representing the elder and younger branches of the Haracleids, the predominant power of the ephors left the kings little more

LIBERTY

than a military command in time of war. But the system administered by the ephors, although depending on the national will, was, as it affected the individual citizen, to all intents and purposes a despotism. It regulated not only all public, but also all private concerns; it interfered with families, and separated the members into classes, who thenceforth existed as a mere political relation; it substituted for domestic life a life of clubs, subjected to a strict routine of employment and the severest sumptuary laws; it placed its ban on all literature, and confined all education to that of the body, and to an absolute submission of the will to a stereotyped order of things. But as the people wished to have it so, the nation was collectively free. The idea of individual freedom was distinctly recognised first at Athens; and if we take the funeral oration of Pericles (Thuc. ii. 35) as a fair exposition of that idea, we can scarcely withhold the admission that the highest modern civilisation has scarcely reached the standard there set forth. In the elaborate comparison which he makes between the policy of Athens and that of Sparta, he lays most stress on the unbounded freedom which the citizens of the former state possessed in the indulgence even of whims and caprices of taste and fancy. According to that picture, every citizen has a right not only to be represented in the government, but to take a personal share in it [PRIMARY ASSEMBLIES]; he has the power of arranging his family, decorating his house, and furnishing his table as he pleases; he is free from all drill and routine, and is not required to prepare himself against the accident of war, by giving up the cultivation of all elegance and grace in times of peace. He may read what books he pleases, and he is free to express whatever opinions he may entertain. The result of this Pericles affirms to be, that Athenian citizens are not surpassed by those of any other states for bravery, presence of mind, and the versatility which is ready to face any emergency, while they are altogether unequalled in their literature and in their appreciation of science and art. An Englishman on reading this account might be forgiven if he saw in it a picture of the civilisation of his own country as compared with that of those continental states of Europe which approach nearest to it in constitutional government. But it must be remembered that the perfect equality of Athenian citizens was, after all, only the equality of an oligarchy, and that it rested on the permanent subjection of a far larger class, in whom a later philosophy saw nothing but animated instruments or machines (*εργαρον εμψυχον*, Aristotle, *Pol.* i. 4. 2). But when all the necessary allowances have been made, it must be admitted that the downfall of the Athenian state closed the brief era of individual freedom, until the seed, long buried, began again to grow within the last few centuries of European history. For, in Rome, the rights and interests of the individual man were but little consulted, and his personal tastes, predilections, and as-

LIBERTY

pirations were at once set aside if they interfered with the interests of the state. This complete subordination of personal to public interests is, perhaps, the secret of the rapid conquests of the republic; but it left all the questions relating to the liberty of the individual citizen altogether unsolved.

With these questions the philosophy of Aristotle dealt in a summary fashion, which presents a complete contradiction to the ideal or the actual polity of Pericles. According to his system, each man is free who lives in a free state, i. e. a state which is not subjected to foreign rule, and which gives to him a share in the administration of the laws. But the power of this state is not limited to the public relations of the citizens. The ethical system of Aristotle is only a part of his political system, and is of value in his eyes only as enabling each man to discharge his duties as a citizen. The state is, therefore, not only justified, but bound to regulate the education and private life of all its members: it is to dictate to them what they are to learn and do, the books which they are to read, and the tastes which they should cultivate. There is, consequently, an imperative need of the most minute legislation for all the circumstances of life (*περὶ πάντα τὸν βίον*, *Eth. N. x. 10*); and this legislation will be obeyed by all decent-minded persons from the mere principle of obedience to law as such. Those who cannot rise to this standard of action will resist; and for these there are pains and penalties which are exactly opposed to the selfish pleasures which they love. The resemblance of this doctrine to that of St. Paul is manifest; but the upshot is that good citizens, in obeying the law, receive their reward in the satisfaction of their own consciences. They have acted as they have done *τοῦ καλοῦ χάριν*, from a disinterested love for that which is beautiful: and this is the highest pleasure to which they can attain. It is, however, an ideal pleasure, with which the positive penalties assigned to wrong action stand out in grim contrast.

Still, for all practical purposes, the province of executive government remains much the same in England now as it was in Greece in the days of Aristotle. It is no part of the business of the state to reward good actions as such. Any harm done to the persons or the property of others, it will promptly repress and punish; but for the performance of the most beneficial and self-sacrificing acts it will leave the citizen, as Aristotle left him, to the approval of his own heart. It becomes, therefore, a matter for simple astonishment when we find such a writer as Bishop Butler deliberately asserting that 'the annexing pleasure to some actions and pain to others, in our power to do or forbear, and giving notice of this appointment beforehand to those whom it concerns, is the proper formal notion of government' (*Analogy*, part i. ch. ii.); and it may fairly be regretted that he should thus, in the supposed interests of a theological dogma, have

LIBITINA

laid down as true in fact a definition which no nation or government has so much as attempted to realise. Certainly, Butler himself did not live in an age in which parliament periodically ordered all persons to feel pleasure for all good deeds which they may have done, and still less offered them the means for procuring this pleasure.

But the progress of modern thought and civilisation tends more and more to restrict the function of government to the protection of person and property. It is felt, therefore, more and more, that with morality and religion, as such, the state has nothing to do; and it is acknowledged that sumptuary or other enactments, designed to regulate the private tastes and habits of citizens, trench on a province which is wholly beyond the reach of human law. Such restrictions, in the measure in which they take effect, necessarily enlarge proportionally the liberty of the individual citizen, and force on our attention those further questions which are discussed at length in Mr. J. S. Mill's work on *Liberty*.

But without attempting to enter on discussions wholly beyond our limits, we may remark that a very real obstacle is placed in the way of personal liberty where all the members of a state, without respect of office and position, are not equally amenable to the law of the land. In this respect, the British constitution stands out in favourable contrast with the most free constitutions of Europe; for whereas in this country all judges and magistrates are liable to prosecution not less than the meanest member of society, under the continental governments no charge can be brought against subordinate officials, of whatever kind, without the written permission of the chief in the department or bureau to which he belongs, while against the chief himself the application of a legal remedy is still more difficult and uncertain. Where this privilege exists, the essential conditions of individual liberty are lamentably imperfect, even if that liberty is not wholly neutralised. This state of things is productive of the greatest mischief in the smallest and the least powerful states, and may be set down as one of the chief causes of that chronic misgovernment under which the modern Hellenic kingdom seems likely to labour for many years to come. Wherever it exists, it must operate as a formidable barrier in the way of that free expression of opinion on all subjects which seems to be of the very essence of political and social freedom. (*Mill On Liberty*, ch. ii.) [REPRESENTATION.]

LIBERTY. In Philosophy. [NECESSITY.]

Libethenite. A native phosphate of copper, found in cavities in Quarz, at Libethen, in Hungary, associated with Iron Pyrites.

Libitina (Lat.). An Italian goddess, in whose temple, at Rome, was deposited a small coin, called *Libitinæ ratio*, for every person who died. This custom, which originated in the desire to procure a faithful account of the number of deaths, may, perhaps, be regarded

LIBOCEDRUS

as among the first attempts to obtain an accurate census of the population.

Libocedrus (Gr. *Libanus, incense*; *κέδρος*, the cedar-tree). A genus of Chilian and New Zealand *Conifera*, related to *Thuja*. *L. Doniana*, the Kawaka of New Zealand, is a large tree, yielding a fine-grained heavy timber; while *L. Bidwillii*, from the same country, has wood so soft and porous that soap bubbles may be blown through a piece a foot long. The Chilian *L. tetragona* and *L. chilensis* are valuable timber trees. The grain of the former is so straight and equal, that the wood can be split into shingles which look as though they had been dressed.

Libra (Lat. *the balance*). One of the zodiacal constellations, the seventh in order, beginning with Aries. Libra is one of the forty-eight ancient constellations of Ptolemy.

LIBRA denotes also the ancient Roman pound. [WEIGHTS.]

Libraries, Itinerating. The name given to a peculiar species of circulating library, instituted a few years ago at Haddington, in Scotland, by Mr. Samuel Brown. The principle on which such libraries are formed consists, as the epithet *itinerating* implies, in the books being sent from one part or district of a country to another on the following plan: The books are formed into divisions, consisting each of a certain number of volumes, and proportioned in number to the extent of the country intended to be supplied. Each division remains for a certain period (in some instances one or two years) in the same place, when it is removed to another, and succeeded by a new supply of books of the same number; by which means each place has a fresh supply of useful reading at short stated intervals. In Haddingtonshire, which may be called the head-quarters of itinerating libraries, the books consist of 43 divisions of 50 volumes each: and on the principle above explained each volume, at an average of the 43 divisions, is read five times during two years, the period at which the books are changed. The system of itinerating libraries has been extended to various other parts of Scotland, to several districts of England, to Ireland, Canada, South Africa, and Jamaica. The use of the books is gratuitous, if so wished; and never more than a penny per annum has been systematically taken from any reader. Voluntary contributions, however, either in books or money, are received. (*Geographical Dictionary*, art. 'Haddington.')

Library (Lat. *liber, book*). The name given either to a collection of books, or to the apartment or edifice in which they are kept. The most famous of ancient libraries was that of Alexandria. Its history has been written by Bonamy (*Mém. de l'Acad. des Inscriptions*, vol. ix.), Reinhard (Götting. 1792), and many others. It was first formed by the Ptolemies, Soter, Lagides, Philadelphus and Euergetes; the last of whom resorted to very royal measures for the accomplishment of so laudable an

LIBRARY

end; for he is said to have seized on books imported from Greece, caused them to be copied, and returned the copies to the proprietors, keeping the original for his library. The collection of Soter is said to have been deposited in a suburb called Bruchium, which was burnt by the troops in Caesar's Egyptian war. That of Philadelphus (the smaller of the two) was preserved in the temple of Serapis, and became the nucleus of the later library, which was augmented by the great library of Pergamus (said to have amounted to 200,000 volumes), presented to it by Mark Antony. The narrative of the destruction of this library by the fanatical Arabs, in A.D. 641, is among the popular chapters of history; and the most careful enquirers are of opinion that it is substantially, if not literally, true, notwithstanding the doubts thrown on it by Gibbon and others. The first public library at Rome was founded by Asinius Pollio; the second, the Palatine, by Augustus; great part of it was consumed under Commodus; but much remained even in the time of Constantine. Rensch (1734), Eckerman (1764), and Eckhart (1799), have published separate dissertations on the libraries of the Romans. The ancient libraries of the West must have wholly perished in the convulsions which attended the overthrow of its empire. The history of those of the East is not easy to investigate. Constantinople certainly possessed, at the period of its capture, extensive remains of ancient literature; and many, but almost wholly fruitless investigations, have been made of late years in the monastic libraries of modern Greece, particularly of Mount Athos, for valuable manuscripts. (Walpole's *Oriental Memoirs*; *Journal of Education*, vol. ii.; Cuzon's *Monasteries of the Levant*.) The best accounts of ancient libraries to which we are able to refer the reader, are contained in the work of Petit Radel, *Recherches sur les Bibliothèques Anciennes et Modernes*; Heeren, *History of the Study of Classical Literature*, vol. i.; Ersch and Gruber's *Encyclopædia*, art. 'Bibliotheken'; Taylor's *History of the Transmission of ancient Books in modern Times*; *Ency. Brit.* art. 'Library.'

Of modern public libraries, the most celebrated is that of Paris (Bibl. Impériale). It was commenced by King John, in the middle of the fourteenth century, with ten volumes; and has been augmented by subsequent kings to the enormous number which it now possesses. (Le Prince, *Essai Historique sur la Bibl. du Roi*, Paris 1787.) In Italy, the Ambrosian at Milan, and the Vatican at Rome, are peculiarly rich in MSS. But the most extensive are those of the British Museum. That of Oxford (the Bodleian) is peculiarly rich in Oriental manuscripts. That of the Advocates, at Edinburgh; and of Trinity College, Dublin, are extensive. Statements of the number of books contained in public libraries will be found in many works; but no statistical information is more imperfect and worthless.

LIBRATION

Premising thus much as to the uncertainty of our materials, we offer the following estimate of the contents of some of the principal libraries of Europe.

Great Britain.—British Museum (1864), 780,000 printed volumes (the additions now exceed 40,000 per annum), MSS. (1864) 80,800. Bodleian, Oxford, printed volumes (1862) 400,000, MSS. 30,000. Advocates', Edinburgh (1857), 172,000.

France.—Impriales (1862), more than 500,000 printed, besides 450,000 pamphlets or sheets, 84,000 MSS.

Germany.—Munich, probably from 400,000 to 500,000 printed, 10,000 MSS. Vienna (1853), 365,000 printed, 20,000 MSS. Berlin, 460,000 printed, 10,000 MSS. Göttingen (1850), 300,000 printed, 6,000 MSS. Dresden (1853), 305,000 printed.

Italy.—Vatican, 150,000 printed, 40,000 MSS. Public Library, Naples, 200,000 printed, 4,000 MSS.

Russia.—Imperial of St. Petersburg (1857), 520,000 printed, 21,000 MSS. Denmark, Copenhagen, 408,000 printed, 15,000 MSS.

Libration (Lat. *libratio*, from *libra*, a balance). In Astronomy, a term applied to certain phenomena connected with the moon's motion.

The libration is of two kinds; the libration in longitude and the libration in latitude. The libration in longitude, by which we are enabled to look a few degrees round the equatorial parts of her eastern and western limbs, is occasioned by this circumstance, that the rotatory motion of the moon about her axis is not always precisely equal to the angular velocity in her orbit. If the moon's orbital motion were uniform, and performed in the same time as her rotation about the axis, the radius vector from the centre of the earth would always intersect the lunar disc in the same point, or the moon would always present exactly the same face to the earth. But the rotatory motion is sensibly uniform; while the orbital motion, being performed in an ellipse, is sometimes slower and sometimes faster than its average amount. Hence the spots near the eastern and western borders alternately disappear and reappear.

The libration in latitude is occasioned by the inclination of the moon's axis of rotation to the plane of her orbit. Supposing this axis always to have the same direction in space, the angle which it makes with the radius vector of her orbit will be acute during one part of her revolution and obtuse in another. Hence the two poles of rotation, and the adjacent parts of the surface, are alternately visible from the earth.

Licence (Lat. *licentia*). In Law, a power or authority given to a man to do some lawful act, and conferred either by word or by deed. If a man abuse a license or authority given to him by the law except in distraining for rent, with respect to which special statutory provisions have been made, he becomes a trespasser ab initio. License is also commonly taken for

LICHEN

the admission of an individual, by proper authority, to the right of doing particular acts, practising in professions, &c., and for the certificate of such admission.

Licentiate. A degree in some foreign universities; but not known in the universities of England, except in the instance of the degree of licentiate in medicine, which is granted at Cambridge. In the original sense of the word it appears to have been a title applied only to such as had obtained a license to teach. It is said to be of Italian origin, and first granted at the university of Bologna. Where the degree of licentiate exists, it intervenes between that of bachelor and that of doctor.

Lich Gate (Ger. *leiche*, a corpse). A shed over the entrance of a churchyard, or a cemetery, beneath which the bearers of the corpse sometimes rested.

Lichanus (Gr. *λεψω*, I lick). The forefinger, used in tasting a small quantity of anything.

Lichen (Gr. *λειχήν*, a roughness of the skin). In Pathology, a papulous eruption of the skin, terminating in scurfy exfoliations: it is generally symptomatic of disordered stomach and bowels.

Lichens (Gr. *λειχήν*). A very extensive natural group of Cryptogams of a very low organisation, which grow on the bark of trees or rocks, when they form a kind of incrustation; or upon the ground, when they consist of irregular lobes parallel with the earth's surface. Occasionally in all situations they are found in a branched state; but their subdivisions are generally irregular and without order. Their fructification consists of hard nuclei, called *shields*, which break through the upper surface of the *thallus* or main substance of the lichen, are of a peculiar colour and texture, and contain the reproductive particles.

Lichens abound in the cold and temperate parts of the world. The greater part are of no known use; but some, as the reindeer moss (*Cenomyce rangiferina*), the Iceland moss (*Cetraria islandica*), and various species of *Gyrophora*, are capable of sustaining life, either in animals or man. The Iceland moss, when deprived of its bitterness by boiling, becomes, indeed, a diet recommended to invalids. Others are used as tonic medicines, as *Varilaria faginea*, and *Parmelia parietina*. Their principal use is, however, that of furnishing the dyer with brilliant colours; orchil, cudbear, and perolla, with many more, are thus employed.

Lichens, Colouring Matters of. Lichens or liverworts are diminutive mossy-looking plants frequently found on old walls, the trunks of trees, &c. in most countries. They all contain definite crystalline substances which become coloured on exposure to a moist warm atmosphere containing ammonia. Foreign lichens are especially rich in these matters, 100,000*l.* worth being annually imported into this country, chiefly from the Canary Islands, for the purpose of making the well-known lilac,

LICHENIC ACID

blue, violet and purple dyes known as *archil*, *oudbear*, and *litmus*. The following is a list of the lichen derivatives; they were nearly all discovered by Stenhouse and Schunk, and the chief of them are treated of in separate articles: *Amethystin*, *azoerythrin*, *beta-orcin*, *chlororocin*, *chrysophanic acid*, *erythrellic acid*, *erythric acid*, *erythrolic acid*, *erythro-mannite*, *evernic acid*, *everninic acid*, *gyrophoric acid*, *lecanoric acid*, *leucorocin*, *litmic acid*, *litmylic acid*, *nitro-erythro-mannite*, *orcein*, *orcin*, *orsellic acid*, *parellic acid*, *picroerythrin*, *pseuderythrin*, *procellinin*, *spaniolitmin*, *telerythrin*.

Lichenic Acid. The acid peculiar to some species of lichens. It appears to be the *malic acid*.

Lichenin. A substance closely allied to starch, extracted from the *Cetraria islandica*, or Iceland moss.

Lichenstearic Acid. A crystalline oily body contained in Iceland moss.

Lichtenberg's Figures. When the knob of a charged Leyden phial is drawn over a flat surface of lac or resin, as, for instance, the plate of an electrophorus, it leaves a charge in its track, positive or negative, as we choose; and if, after this, a mixture of certain powders be sifted upon the plate, as, for instance, of powdered sulphur and red lead, the sulphur will adhere to the one and the red lead to the other electrified surface, and with a little management groups of figures resembling flowers may be thus brought out, as Lichtenberg first observed.

Licks. A term applied in North America to sandy tracts of land, upon which common salt forms an efflorescence, and which almost all graminivorous animals resort to for the purpose of licking the surface.

Lictors (Lat. *lictiores*). Officers who attended the principal Roman magistrates (such as the consuls, master of the horse, and prætors) and the vestal virgins on their appearance in public. Their insignia were the *fascæ* or bunch of rods (originally encircling an axe, which within the walls of Rome was used under the republic only by dictators), and the *virga* or rod, which was used to touch the door of the magistrate on returning home. The number of lictors in attendance varied according to the rank of the magistrate; thus the consuls had twelve, the prætors six, and dictators, according to some, twenty-four.

Licuala (its Macassar name). A genus of palms from India and the Indian Archipelago, one species of which, *L. acutifida*, yields the walking sticks known by the name of *Penang lauvers*. The stems average about an inch in diameter, and five feet or more in height.

Lieberkühne. A pseudomorphous form of *Elasolite*.

Lieberkühn. A silver concave reflector fixed on the object-glass end of a microscope to bring the light to focus on an opaque object.

Lieberkühnian Glands. In Anatomy, simple secreting cavities, having the form

LIEUTENANT

of blind tubular depressions of the intestinal mucous membrane, thickly distributed over the whole surface of the large and small intestines. They are so called after their discoverer Lieberkühn, who observed them in the small intestines, where they are visible only with the aid of a lens, their orifices appearing as minute dots scattered between the villi. They are larger in the large intestine.

Liebigite. A hydrated carbonate of uranium and lime occurring in mammillary concretions or thin crusts of an apple-green colour, near Adrianople in Turkey, and also in Saxony and Bohemia. Named after Baron Liebig.

Liege (in the Latin of the middle ages *ligens*, perhaps from *ligare*, to bind; some writers derived the word *liege* from the Teutonic word *leude*—Mod. Ger. *leute*, *people*—used in the sense of *vassal*). A liege lord, in feudal language, is a superior to whom *allegiance* is owed, and a *liege-man* he who owes such allegiance. Hence all subjects are termed *lieges* of the king.

Lien (Fr. *a bond*). In Law, the right which a creditor has to retain the property of his debtor until the debt has been paid. It furnishes one of very few instances in which a party is allowed to take the law, as it were, into his own hands. Liens are either general or particular. A general lien is the right to retain a thing for a general balance of accounts, and not for those demands only which arise in respect of the thing retained. This sort of lien is not favoured by law, as having a tendency to prefer one creditor to another. A particular lien, which the law is said to favour, is a right to retain a thing when the claim against the owner of it arises out of the thing retained itself; as, where a tailor has made the cloth of his customer into a coat, the tailor may retain the cloth until he is paid for his labour in making it into a coat. The payment of a simple contract debt cannot be enforced by action after six years have elapsed from the time the debt was incurred: but a party who has a lien on property may retain it for an unlimited period, until his claim is satisfied.

Lientery (Gr. *λειερεπλε*, from *λεῖος*, *smooth*, and *ερεπα*, *bowels*). A Medical term formerly applied to a form of diarrhoea in which the food passes rapidly through the bowels in an apparently undigested state. Lubricity of the intestines.

Lieutenant (Fr.; from Lat. *locum tenens*, *holding a place*). In the Army, a commissioned officer next in rank to a captain, in whose absence he takes the command of his company. In the British service the lieutenants of the three regiments of foot guards have the rank of captain. In the marine artillery and marines of the British service, and in all the regiments of most of the Continental nations, there being no cornets or ensigns, the subaltern officers are distinguished as first and second lieutenants. In the royal artillery and engineers there is no commissioned rank lower than that of lieutenant. The daily pay of a lieutenant is:

LIEUTENANT

in the life guards and horse guards, 10s. 4d.; foot guards, 7s. 4d.; cavalry, 8s.; artillery (horse), 9s. 10d.; (foot), 6s. 10d.; engineers, 8s. 10d.; marines and infantry, 6s. 6d.; and the price of his commission, according to the present regulations, is, for the life guards, 1,785*l.*; horse guards, 1,600*l.*; foot guards, 2,060*l.*; cavalry and infantry of the line, 700*l.*

LIEUTENANT. In the Navy, the next rank to that of commander, and coördinate with that of captain in the army, or with that of major after being eight years a lieutenant. The number of lieutenants appointed to ships of war varies with their rate. A ship of the first rate carries eight lieutenants, besides supernumeraries; and those of the second, third, fourth rates, &c. have respectively one less than the number appointed to the preceding rate. The daily pay of a lieutenant in the British navy varies, according to the ship, from 1*4s.* 9d. to 10*s.* His half-pay ranges according to service from 8*s.* 6d. to 4*s.* a day.

Lieut. A commissioned officer in the army, next in rank to a colonel, and senior to a major. He has actual command of a battalion in the line. [**COLONEL.**]

Lieutenant-General. [**GENERAL.**]

lieutenant of the Kingdom.

A dignity equivalent to that of regent, which has been occasionally held in France on temporary emergencies. The count of Artois (afterwards Charles X.) took this title in 1814 on entering France, and held it until the arrival of his brother, Louis XVIII. On the expulsion of Charles X., in 1830, the duke of Orleans was constituted lieutenant-general, both by an ordinance of that prince, and by the provisory government of the Hôtel de Ville, on July 29; and retained the title until he was proclaimed king on August 7 following.

Liévrite. A silicate of iron and lime, named after the discoverer, Le Lièvre. It has also been called *Jenite* and *Revite*, as being found at Jena and in the island of Elba.

Life (Ger. leben). A living thing has been defined by Professor Owen as an object which possesses such an internal cellular or cellulovascular structure as can receive fluid matter from without, alter its nature, and add it to the alterative structure. Such fluid matter is called *nutritive*, and the actions which make it so are called *assimilation* and *intus-susception*. These actions are classed as *vital*, because, as long as they are continued, the organism is said to *live*. Other definitions, formed more or less upon metaphysical bases, have been suggested by physiologists. Bichat defined life as 'the sum total of the functions which resist death,' which has been wittily paraphrased as 'Life consists in being able to live.' Treviranus defined it as 'the constant uniformity of phenomena with diversity of external influences;' Lawrence as 'the assemblage of all the functions or purposes of organised bodies, and the general result of their exercise;' Dugès as 'the special activity of organised bodies;' Béclard as 'organisation in action;' Kant as 'an internal principle of

LIFEBOAT

action;' De Meville as 'the twofold internal movement of composition and decomposition, at once general and continuous;' Herbert Spencer as 'the definite combination of heterogeneous changes, both simultaneous and successive, in correspondence with external coexistences and sequences;' and Mr. G. H. Lewes as 'the dynamical condition of the organism.' The whole question of the correct terminology of the sciences of life is not yet in a sufficient state to be dogmatically decided.

Life Anxusity. [**ANXUSITY.**]

Life Assurance. [**ASSURANCE.**]

Life Buoy. An apparatus carried on ship-board, pier, &c. for the purpose of throwing to a person who has fallen into the water, to enable him to sustain himself until the arrival of assistance. The commonest form is a cone of about thirty-one inches in diameter, six inches wide and four inches thick. It is formed of about twelve pounds of cork in thin layers; the whole being held together by a painted canvas case. Such a buoy will sustain six persons. Some life buoys comprise a short mast to carry a flag for daylight, or a composition which at night burns for some minutes with a powerful light. The object of this arrangement is to attract the attention of the drowning person.

Life Guards. Cavalry troops composing the body guard of a sovereign prince. In England they consist of two regiments, each comprising a total of 440 of all ranks. There is also a regiment of horse guards performing the same duties. -In Germany such troops are styled the *leib garde* (body guard); and in France the *garde du corps*. The English name is, therefore, only catachrestic. [**GUARDS.**]

Life Line. In a Ship, any rope stretched along for the safety of the men, as is practised in bad weather; also lines attached loosely to a life buoy to give a person in the water more chance of obtaining a hold upon it.

Life, Mean Duration of. [**EXPECTATION OF LIFE.**]

Life Rent. In Scottish Law, the right of enjoyment either of an heritage or a sum of money, for the life of the life renter. The superior proprietor of the subject, or *fee*, in which this rent subsists, is termed the *far*. *Tercie* (i. e. dower) and *courtesy* (analogous to the courtesy of England in English law) are instances of legal life rents.

Life-preserving Apparatus. This apparatus, employed to effect communication between a stranded vessel and the shore, consists in our service of a cast-iron shot carrying a leather thong, to which a long line is secured. There are four fuse holes from which flame issues when the shot is fired. Before firing, the fuses are uncapped, and the shot is placed in the bore of the gun base foremost. This apparatus is also known as *Manby's shot*.

Lifboat. A boat devoted to the saving of life which would otherwise be sacrificed from the violence of the sea. As its service is only in the most tempestuous weather, it is indis-

pensable that it should be of great strength yet moderate lightness, easy of management, and incapable of being swamped. Several designs have received more or less favour, and have each been instrumental in saving many lives. The present lifeboat, as adopted by the Royal National Lifeboat Institution, is the invention of Mr. Peake, now master-shipwright of Devonport Dockyard. It consists of a strong boat about thirty feet long, and eight wide, to give great stability. It is nearly flat-bottomed; but the bow and stern (which are alike) rise about two feet higher than the midship portion. Running along the upper part of each side, and occupying four feet in length of bow and stern, are air-tight chambers which impart buoyancy, and are sufficient to float the boat and crew when filled with water. Should the boat by any chance capsize, it would rest on the raised points of the bow and stern; but as it has a heavy iron keel weighing seven or eight hundredweight, it is very nearly impossible for it to turn over, and if it do capsize it is wholly impossible for it to remain many seconds without righting itself. The iron keel is also of great advantage on taking the beach or grazing a rock. The boat has—and this is its distinctive feature—a false bottom sufficiently raised to be above the water-line when it is fully laden with crew and passengers. The space between the false bottom and the bottom of the boat is tightly packed with pieces of cork and light wood; and passing right through this ballast from the false bottom to the water below are open tubes about six inches in diameter. If a sea be shipped and the boat filled, the water is immediately discharged through the tubes, since the false bottom is above the water-line. The lifeboat is propelled by eight to twelve oars of the best fir: usually rowed double-banked.

For carriage on board ship this land lifeboat is too cumbersome; and, for this purpose, an ingenious folding lifeboat has been invented by the Rev. E. L. Berthon, of Fareham, which readily expands and possesses great strength. It is much used by ocean steamers.

Lift-tenter. The name given in some parts of England to a sort of regulator or governor applied to windmills to counteract the irregular action of the wind. In a windmill for grinding corn, the distance between the upper and lower millstones is regulated according to the velocity; and if, when the mill is at work, the velocity should receive any considerable increase, the corn is forced rapidly through the mill without being sufficiently ground. To prevent this is the object of the lift-tenter. Like the governor of a steam engine, it acts by the centrifugal force of one or more balls which fly out when the velocity is augmented, and as they rise in the arc of a circle, allow the end of a lever to rise with them, while the other end descends with the upper millstone, and brings it a little nearer to the under one.

Lifting Jack. A simple mechanical arrangement for raising one end of the axle-tree of a carriage, and so lifting the wheel from the

ground; the wheel can then be removed, or turned round for the purpose of being cleaned.

Lifting Pump. [PUMP.]

Lifts. On Shipboard, the ropes used for hoisting, lowering, and maintaining in position the several yards. They pass in pairs over the head of the mast on which the yard is suspended, and thence to the deck or to the tops.

Ligaments (Lat. *ligamentum*, from *ligo*, *I bind*). Strong elastic membranes connecting the extremities of the movable bones. When boiled in water they yield more or less gelatine, and leave a portion of insoluble albumen.

Ligature (Lat. *ligatura*, from *ligo*). In Music, the tie which binds several notes of like length together, by which they appear in groups.

Thus  four quavers, by means of a ligature at top or bottom, assume the form , the line connecting them being the ligature.

LIGATURE (Lat. *ligo*, *I bind*). In Surgery, a waxed thread of silk used in tying arteries or veins.

Ligatures. In Printing, two or more letters cast on one piece or shank. They are also called *logotypes* (word-types), a name given them by the late Earl Stanhope. They have never succeeded in a commercial point of view, although great efforts were made some few years back by Major Beniowski to induce the House of Commons to accept his logotypes for printing their work. The precursor of the *Times* newspaper (the *Universal Register*), as well as the first few numbers of the *Times* itself, were printed with logotypes; and the founder of these journals, Mr. J. Walter, in the first number of the *Register*, published Jan. 1, 1785, tells his readers that he considers the new mode so economical that he can in consequence afford to sell his paper at 'one halfpenny under the price paid for seven out of the eight morning papers.'

The ligatures now in use are few in number, having been reduced to æ, œ, ff, ffi, fi, and f; but within the last forty years we had also the Ç, ç, ß, ð, ñ, ò, ï, and ð, now discarded mainly in consequence of our confining ourselves entirely to the short s. The & is the modern form of the Ç, the e and i joined together for ð. Earl Stanhope proposed to abolish the present ligatures by making the f more upright without being kerned, so as to admit an i or an l or another f after it, and to introduce others which occur more frequently, viz. th, in, an, re, se, to, of, and on.

Greek Ligatures.—In former times Greek was printed as written in the middle ages, with an immense number of ligatures, some easily decipherable, but most of them not intelligible even to good Greek scholars of the present day. A list, perhaps the most complete, was compiled by the late Mr. Savage from various sources, and is given in his *Dictionary of Printing*.

Light (Ger. *licht*, Lat. *lux*, Gr. *lúmen*, Sansc. *lôk*, to look or see). The phenomena of light and vision have always been regarded

LIGHT

is one of the most interesting branches of natural science; though it is only since the days of Newton that they have been examined with such care as to afford grounds for any safe speculation respecting the nature of light, and the mode of its propagation through space.

The knowledge of the laws which regulate the phenomena of light constitutes the science of *Optics*, which is divided into a number of subordinate branches. An account of the principal phenomena will be found under the terms *ABERRATION, CHROMATICS, INTERFERENCE, OPTICS, POLARISATION, REFLECTION, REFRACTION, &c.* The present article will be confined to a brief enumeration of some of the principal properties of light, and a statement of the two theories which have been proposed to explain its nature and propagation.

Properties of Light.—Experiments of the simplest and most familiar kind suffice to show that light is propagated from luminous bodies in all directions. Thus, the flame of a lamp is visible from every part of the sphere of which it occupies the centre; and the same is the case with respect to a phosphorescent body, an electric spark, a ball heated red-hot, or light having any other source. The sun throws its light, not only on the earth, but on the planets, and comets, and every other body in the firmament.

Another property of light is, that in a homogeneous medium it is always propagated in straight lines. This is evident from various considerations. The forms of shadows correctly represent the outlines of the objects which produce them, as seen from the luminous body, which could not be unless the light proceeded in straight lines from the extremities of the objects to the borders of the shadow. If three plates of metal, each pierced with a small hole, are placed at some distance behind each other, and in such positions that the three holes are exactly in one straight line, the light will pass freely through them; but if the holes are not exactly in a straight line, no light will pass. In like manner, if a number of similar objects are placed behind each other in a straight line, the first renders all the others invisible to an eye placed in the same line. We cannot see through a bent tube.

A third property of light is that it requires time for its propagation. The velocity with which it passes from one point to another is, however, so great, that, with respect to any terrestrial distances, the passage may be considered as instantaneous. But astronomy furnishes the means, not only of detecting its propagation, but of measuring its velocity with great precision. The eclipses and emissions of Jupiter's satellites become visible about 16 m. 26 s. earlier when the earth is at its least distance from Jupiter, than when it is at its greatest. Light, therefore, occupies above a quarter of an hour in passing through the diameter of the earth's orbit. Now, the sun's distance from the earth being nearly 93,000,000 miles, it follows that light must travel through space with the prodigious though

finite velocity of about 193,000 miles in a second of time, and consequently would pass round the earth in the eighth part of a second. Astounding as this conclusion is, no result of science rests on more certain evidence. It is also proved, by the phenomena of aberration, that the light of the sun, planets, and all the fixed stars, travels with one and the same velocity.

When light in its progress encounters an obstacle, or enters a different medium, it undergoes certain modifications, depending on the nature of the body on which it falls, or the medium into which it enters. When it falls on a smooth polished surface, a portion of it is regularly reflected; that is to say, it is returned from the surface at an angle equal to the angle of incidence, and pursues its course in a straight line as before the reflection. The quantity of light thus reflected depends on the nature and polish of the surface, and on the angle of incidence, the amount being greatest when that angle is small. A polished surface of silver, the most perfect reflector of light known, reflects about 91 per cent. of the incident rays, whilst a polished surface of glass at a small angle of incidence reflects only about 4 per cent. If the medium upon which the light falls be transparent another portion of it enters the medium, and there (if the medium is homogeneous) pursues a rectilinear course, but differing from its former direction, unless the surface of the medium be at right angles to the track of the ray. In this case it is said to be refracted. The angle of refraction depends on the nature of the medium, each different medium having its own peculiar action on light. In many media, comprehending the liquids and most of the uncrystallised substances, the whole of the refracted light is bent from its original direction at the same angle. In many others, as in most crystallised media, part of the refracted light follows one course, and another part of it a different one; the two portions acquiring at the same time different physical properties. In this case the refraction is said to be double, and the light becomes polarised. [POLARISATION.] A portion of the light falling on a body is reflected irregularly, and is scattered in all directions; it is this portion which renders bodies visible. All bodies on which light falls absorb a certain part of it; more or less in proportion to their opacity. In perfectly opaque bodies the absorption is total, and the light does not penetrate to a sensible depth under the surface. In others it penetrates farther; but even in the most transparent it is gradually extinguished. A depth of only seven feet of pure water is required to absorb one-half of the incident light. [REFLECTION.]

Solar light, refracted by a prism or other body, is separated into a multitude of rays of different colours, each of which afterwards proceeds in its course independently of all the others. These differently coloured rays possess different physical properties and different degrees of refrangibility. The investigation of

LIGHT

the laws of the dispersion of the coloured rays forms the subject of *chromatics*. One of the principal facts connected with it is, that the dispersion of the rays by different refracting substances is not proportioned to the refraction; the dispersive power of some substances being greater than that of others, while their refracting power is less. This fact led to the important discovery of the *achromatic telescope*. [ACHROMATISM; CHROMATICS.]

Light, on being regularly reflected or refracted, undergoes a modification termed *polarisation*, in virtue of which it presents, on encountering another medium, different phenomena of reflection and refraction from those presented by light which has not undergone such modification. [POLARISATION.]

The last property of light which we shall notice, as important towards forming a theory of its propagation, is that to which Dr. Young gave the name of *interference*. Under certain circumstances, the rays of light exercise a mutual influence on each other; increasing, diminishing, or modifying each other's effects according to certain laws. This mutual action of the rays on each other gives rise to a great number of the most beautiful and interesting phenomena of optics. These are described under the term *INTERFERENCE*.

Theories of Light.—Two different theories have been proposed regarding the nature and propagation of light. One of these consists in supposing it to be composed of particles of excessive minuteness, projected from the luminous body with a velocity equal to about 193,000 miles in a second. This hypothesis was adopted by Newton. The other hypothesis supposes light to be produced by the vibrations or undulations of an ethereal fluid of great elasticity, which pervades all space and penetrates all substances, and to which the luminous body gives an impulse which is propagated with inconceivable rapidity, in spherical superficies, by a sort of tremor or undulation, as sound is conveyed through the atmosphere, or a wave along the surface of water. The former theory has been totally abandoned, and we may therefore devote our attention exclusively to the latter, which is termed the *undulatory theory*. The principles of the undulatory theory are thus stated by Sir J. Herschel:—

1. 'That an excessively rare, subtle, and elastic medium, or *ether*, fills all space, and pervades all material bodies, occupying the intervals between their molecules; and, either by passing freely among them, or by its extreme rarity, offering no resistance to the motion of the earth, the planets, or comets, in their orbits, appreciable by the most delicate astronomical observations; and having inertia, but not gravity.

2. 'That the molecules of the ether are susceptible of being set in motion by the agitation of the particles of ponderable matter; and that when any one is thus set in motion it communicates a similar motion to those adjacent to it, and thus the motion is propagated farther and

farther in all directions, according to the same mechanical laws which regulate the propagation of undulations in other elastic media, as air, water, or solids, according to their respective constitutions.

3. 'That in the interior of refracting media the ether exists in a state of less elasticity, compared with its density, than in *vacuo* (i.e. in space empty of all other matter); and that the more refractive the medium, the less, relatively speaking, is the elasticity of the ether in its interior.

4. 'That vibrations communicated to the ether in free space are propagated through refractive media by means of the ether in their interior, but with a velocity corresponding to its inferior degree of elasticity.

5. 'That when regular vibratory motions of a proper kind are propagated through the ether, and, passing through our eyes, reach and agitate the nerves of our retina, they produce in us the sensation of light, in a manner bearing a more or less close analogy to that in which the vibrations of the air affect our auditory nerves with that of sound.

6. 'That as, in the doctrine of sound, the frequency of the aerial pulses, or the number of excursions, to and fro, from the point of rest made by each molecule of the air, determines the pitch or note; so, in the theory of light, the frequency of the pulses, or number of impulses made on our nerves in a given time by the ethereal molecules next in contact with them, determines the *colour* of the light; and that as the absolute extent of the motion to and fro of the particles of air determines the *loudness* of the sound, so the *amplitude* or extent of the excursions of the ethereal molecules from their points of rest determines the brightness or intensity of the light.'

That the sensation of light is produced by the vibrations of an extremely rare and subtle fluid, is an idea that was maintained by Descartes, Hooke, and some others; but it is to Huygens that the honour solely belongs of having reduced the hypothesis to a definite shape, and rendered it available for the purposes of mechanical explanation. Owing to the great success of Newton in applying the corpuscular theory to his splendid discoveries, the speculations of Huygens were long neglected; indeed, the theory remained in the same state in which it was left by him till it was taken up by our countryman, the late Dr. Young. By a train of mechanical reasoning, which in point of ingenuity has seldom been equalled, Dr. Young was conducted by some very remarkable numerical relations among some apparently most dissimilar phenomena of optics, to the general laws of diffraction, and to the true principles of the colouration of crystallised substances. 'It is a theory,' says Herschel, 'which, if not founded in nature, is certainly one of the happiest fictions that the genius of man has yet invented to group together natural phenomena, as well as the most fortunate in the support it has received from whole classes of new pheno-

LIGHT

mena, which at their discovery seemed in irreconcilable opposition to it. It is, in fact, in all its applications and details, one succession of *felicités*; inasmuch that we may almost be induced to say, if it be not true, it deserves to be so.' (*Ency. Metr. 'Light,'* § 695; Sir J. Herschel's *Treatise on Light*; *Airy's Mathematical Tracts*; Brewster's *Optics*; Young's *Lectures*; Biot, *Traité de Physique*; Pouillet, *Éléments de Physique*; Hunt's *Researches on Light*.)

An account of the principal *photographic processes* will be found under the term *PHOTOGRAPHY*.

LIGHT. In Painting, the medium by which objects are discerned. In a picture it means the part which is most illuminated. This may happen from *natural light*, as the sun or moon; or from *artificial light*, as a fire, candle, &c. The principal light is generally made to fall on the spot where the principal figures are placed, and generally near the centre of the picture. A reflected light is that which a body in shadow receives from a contiguous light object.

Light Ball. In Artillery, a cylindrical wrought-iron skeleton with hemispherical ends, covered with canvas, and filled with a composition of saltpetre, sulphur, resin, and oil, which, when ignited, burns for some time with a red flame. Light balls are employed in the defence of fortresses to discover the working parties and assaulting columns of the enemy, into whose trenches they are thrown.

Light Cavalry. Cavalry especially adapted by the lightness of their equipment, &c. for detached duties, skirmishing, &c. In our service cavalry is classed as *heavy*, including the 4th and 5th dragoon guards, and 1st and 2nd dragoons; *medium*, including the remaining régiments of dragoon guards and dragoons and the lancers; and *light*, including the hussars only.

Light Infantry. An honorary distinction by which eleven régiments of the line are called. They do not differ in any essential particular from the rest of the line.

Light Room. A small chamber adjoining, but isolated from, the powder magazine in a ship. It is separated from the latter by a glass partition, through which the light of the lanterns in the light room is thrown. The object is to prevent any combustible matter being taken into the magazine itself.

Lights, Artificial. Artificial light, in the practical acceptance of the term, always emanates from solid matter heated to whiteness, and in nearly all cases this solid matter is carbon. The most common sources of artificial light are coal-gas, oil, and candles, the flames of each of which are composed of jets of burning gas containing little particles of white-hot carbon. The first of the three is made at a distance, and conveyed to the burners by pipes; the other two are made on the spot, or the oil is decomposed into gas by the heat of the flame; and tallow or wax, being first melted by the heat, is then decomposed in a similar manner. Naphtha and other hydrocarbons resemble oil in con-

LIGHTHOUSE

taining carbon, and on being heated also give a jet of combustible gas containing floating particles of ignited carbon. Even the *electric light* proceeds from particles of white-hot carbon; the heat, however, being derived from the electric force instead of the chemical, as in the previously mentioned cases; by this means the carbon is made more intensely hot, and therefore gives out more light. The heat produced by the chemical action of the gas and air in common flames cannot easily be increased without too rapidly burning up the particles of carbon, that should yield light; under these circumstances, therefore, the flame will give less light. This occurs when excess of pure oxygen or even air is blown into the interior of such a flame; heat is then produced at the expense of light. But this heat can be utilised by introducing other solid matter into the flame, such as platinum wire, a lump of lime, even a piece of tobacco-pipe, or any similar solid that does not fuse or burn away. Such an arrangement forms the so-called *lime light*, frequently used for signalling and for exhibiting dissolving views.

Lights, Northern. [*AURORA BOREALIS.*]

Light-ship. A floating lighthouse. It is anchored firmly in positions where the bottom or the depth renders a fixed structure inapplicable.

Lighter. A strong vessel or barge for transporting goods or stores, chiefly on rivers or canals, or between vessels and a shore which they cannot approach on account of their draught.

Lighthouse. An establishment for the exhibition of a light or landmark to direct the mariner. The use of lights for such a purpose is of very high antiquity; but their early history is involved in much obscurity. In the ancient world there were lighthouses at Ostia, Ravenna, Puteoli, Caprea, Rhodes, on the Thracian Bosphorus, &c.; but by far the most celebrated lighthouse in antiquity was that erected by Ptolemy Soter on the small island of Pharos, opposite to Alexandria—'*nocturnis ignibus cursum navium regens.*' (Pliny, lib. v. c. 31.) Its extraordinary height, which some authors have estimated at 500 feet and upwards, procured for it a place among the wonders of the world; and, according to Josephus, its 'beaming summit' could be seen at a distance of 300 stadia—about 42 British miles. It is said to have cost 800 talents; and its celebrity was such that Pharos rapidly became, and still continues to be in many countries, a generic name equivalent to *lighthouse*.

The most celebrated lighthouses of modern times are: the Tour de Corduan, at the entrance of the Gironde, in France; the Eddystone lighthouse, opposite to Plymouth Sound; and the lighthouse constructed on the Ball Rock, opposite to the Frith of Tay. The first of these was begun in 1684, and finished in 1611. It is 186½ feet (English) in height; and besides being of the highest importance to the sailor on so dangerous and frequented a coast,

LIGHTHOUSE

it is at the same time a splendid architectural work. The Eddystone lighthouse, constructed by the celebrated engineer Smeaton, was completed in 1769. It is regarded as a masterpiece of its kind; and, as has been well remarked, it bids fair to be little less lasting than the rocks upon which it stands. The Bell Rock lighthouse was built by Mr. Stevenson on the model of the Eddystone. Numerous lighthouses, marking the most dangerous points, and the entrances to the principal harbours, are now erected in most civilised maritime countries. (The Trinity Board now regularly publish lists of all these lights.) But the coasts of no country are so well provided with lighthouses as those of the United Kingdom. For England, they are under the management of the Brethren of the Trinity House; for Ireland, under that of the Board for the Improvement of the Port of Dublin; and for Scotland, under that of the Commissioners of Northern Lighthouses meeting at Edinburgh.

The ancient mode of exhibiting lights as beacons to the mariner consisted in burning wood or coal in a chauffer on the top of a tower; and till the year 1807, the Eddystone light was nothing better than the feeble blaze of a few tallow candles, without any apparatus for concentrating the light or giving it any particular direction. Afterwards, however, Argand oil-lamps of great illuminating power were employed, and recently the magneto-electric light has been most successfully introduced into the South Foreland and Dungeness lighthouses; and it can scarcely be doubted that this intense light will soon be generally used in lighthouses.

As rays of light proceeding from a luminous body are equally dispersed over the surface of the sphere which has the luminous body for its centre, it is evident that without some means of giving the light a horizontal direction, the greater part of it must be wholly lost; for only those rays which are directed in the plane of the horizon, or at least which are depressed only a few degrees below it, can be seen from a ship at a distance. Hence the first object to be attained is to prevent the loss of light by throwing the whole of it forward in the plane of the horizon, in order that its intensity may be increased in the greatest possible degree. Now there are two principles on which this may be accomplished—reflection and refraction. The object is accordingly carried into effect by a catoptric or dioptric apparatus. Sometimes both principles are combined in the same apparatus.

Catoptric System.—The usual mode of applying the catoptric principle is by placing the source of light in the focus of a parabolic mirror. This mode of illumination appears to have been first carried into effect at the Corduan lighthouse above mentioned, under the direction of Borda, about the year 1780. A few years later reflecting mirrors were placed in some of the English lighthouses, under the direction of the Trinity House; and in 1786 the principle was adopted in the only two

beacons then existing on the coast of Scotland—viz. the Isle of May in the Firth of Forth, and the Cumbrae Isle in the Clyde. Soon afterwards it was adopted generally in this country. Borda's reflector was formed of a sheet of copper plated with silver; those applied in Scotland were formed of small facets of mirror glass, placed in hollow parabolic moulds of plaster. The mirrors in general use in the British lighthouses at the present time are of copper coated with silver; the focal length is about three or four inches, and the diameter at the outer edge about twenty-one inches.

In order to produce a light of sufficient intensity, several parabolic mirrors, sometimes as many as eight, are placed on a frame, with their axes all parallel to each other, so that the light reflected by all of them is blended together in the same beam. To form a revolving light, the frame is attached to a horizontal axis, which is turned by means of clock machinery; and in this manner the different quarters of the horizon are successively illuminated. But as a rapid motion would be inconvenient, the frame has usually three or four sides, on each of which the same number of mirrors and lights is placed; so that the illumination is repeated three or four times in one revolution. To form a stationary light, a number of reflectors are placed round a circular frame, having their axes on the radii of the circle. This arrangement has one obvious defect; namely, that the illumination will not be equally intense at all azimuths, but strongest in the direction of the several axes, and feeblest in the direction of lines bisecting the several angles formed by each pair of contiguous axes. The defect is one which cannot be entirely remedied in a stationary light on the catoptric principle.

Dioptric System.—The introduction of lenses for the purpose of giving the light a horizontal direction is of recent date. A project for this purpose is indeed mentioned by Smeaton in his account of the Eddystone lighthouse, and about the end of the last century the method was tried in some lighthouses in the south of England; but from the imperfect figure of the lenses, and the absorption of the light caused by the great thickness of the glass, it did not succeed. But the art of grinding spherical lenses having been since brought to greater perfection, and a means of greatly diminishing the absorption, and also of constructing lenses of a much greater size, having been found in the use of polygonal lenses (that is to say lenses formed of several pieces separately prepared and afterwards united) [POLYGONAL LENSES], the system has been revived of late years, and in many instances carried successfully into execution. The merit of first applying such lenses to lighthouses belongs to the late Auguste Fresnel, of the Academy of Sciences of Paris. The annular lenses, constructed under the direction of Fresnel, for the principal lighthouses in France, are

LIGHTHOUSE

plano-convex, having a focal distance of about three feet; and they are formed of crown glass as being less liable to *strive* than flint glass.

The construction of a revolving dioptric apparatus of the first order is usually as follows: The revolving frame which carries the principal lenses has eight sides; and there are consequently eight large lenses, so arranged that their axes are all in the same horizontal plane, and meet in the common focus, where the lamp is placed. This frame, with its lenses, consequently forms an octagonal prism. For the purpose of preventing the loss of the rays which fall above and below the principal lenses, various methods are employed. One is to place above the first frame a second frame, whose sides form the frustum of an octagonal pyramid of 50° of inclination, in each of the sides of which is placed a lens having its focus in the flame of the lamp. The rays falling on these inclined lenses are refracted into directions parallel to the axis of the lens, and are then reflected into the horizontal direction by plain mirrors placed above the second frame. Another method is to place curved reflectors above the frame containing the principal lenses. But a third and still more elegant method, proposed by Fresnel, is to substitute for the upper lenses and mirrors a series of triangular prisms, having their axes arranged in horizontal planes, and so adjusted that the light falling on the face next the flame is thrown upon the back of the prism, where it suffers a total reflection; and a second refraction at the third side of the prism gives it the horizontal direction.

For fixed lights on the dioptric system, it is necessary to increase the number of the lenses, which in fact ought to be infinite, or to form a true cylinder, in order to produce an equal diffusion over every point of the horizon. In some of the French lighthouses the refracting apparatus consists of a polygonal belt of thirty-two lenses; but on establishing a dioptric apparatus at the Isle of May lighthouse, in 1836, Mr. Alan Stevenson proposed to form a true cylindric belt; and the task, though attended with much difficulty, was successfully executed at a glass-house in Newcastle.

A plan of the arrangement of the lenses for lighthouses, produced by Messrs. Chance at the Great Exhibition of 1862, combines the principles of Fresnel's fixed and revolving lights with an improved method of reflection; and does away with the use of metal reflectors.

The dioptric system is peculiarly adapted for fixed lights; and its advantages are these: 1. A light of equal intensity is distributed round every point of the horizon. 2. The consumption of oil is less for the same intensity of light, and consequently the expense of maintaining the light is less. 3. The trouble attending it is less, as there is only one lamp to trim, and the lenses are easily kept in order; whereas the reflecting surfaces require much care and attention. On the other hand, there is more

risk from accident, for the accidental extinction of the lamp leaves the whole horizon in darkness; whereas in a system of reflectors the light would be extinguished over only a small portion of it.

One of the most important advances of recent times in lighthouse illumination is the introduction of the electric light, which, thanks to an admirable arrangement invented by Mr. Holmes, may be made as tractable as the oil light, which doubtless it is destined in time to supersede. The more the light-source can be reduced in size, the more does the light-grasping arrangement of Fresnel come into play. The electric light being a point, can thus be wholly utilised, while its intensity is such that not only is it possible to produce a beam giving light enough to read by some ten or twenty miles off, but to *penetrate mists*, a quality which ought to be the sine qua non of the light used in lighthouses. We regret we have not space to give a description of Mr. Holmes' arrangement; one will be found, however, in the *Reader*, vol. ii. p. 701. With regard to the comparative cost of the electric and oil lights, the French Director-General of Lighthouses has reported that, both as to first cost and cost of maintenance, the electric light is the cheaper of the two, the quantity of the manufactured article—light—produced being taken into account.

Method of distinguishing Sea Lights.—An object of great importance in the establishment of lighthouses is to vary the appearances of the different lights so that each may have some distinctive character by which it may be readily recognised, and the mariner be made aware of the part of the coast which he is approaching. Among the methods adopted for this purpose are the following: 1. The interposition of coloured shades before the lenses or refractors, so as to give a particular colour to the light: red is the only colour which can be used, as shades of any other colour are found to absorb too much light. 2. The time of revolution, or the length of the interval between the successive appearances of the light: this is the only mode of distinguishing lights adopted on the French coasts. 3. A *flashing light*; that is, a light of which the alternate flashes and eclipses succeed each other so rapidly as to give the appearance of a succession of brilliant scintillations. 4. An *intermittent light*, which consists of a fixed light which is suddenly eclipsed, and after a stated interval as suddenly revealed: the appearance of this light is entirely different from that of any revolving light. 5. The exhibition of a double light, which admits of other distinctions; for the one light may be placed vertically above the other, or in the same horizontal plane; or one may be white and the other red. Sometimes three lights are necessary to indicate the entrances to harbours, &c.

The average annual expense of maintaining land light in Great Britain is about 500*l.*, and that of a floating light about 1,200*l.*

Lightning. An electric phenomenon, produced by the passage of electricity between one cloud and another, or between a cloud and the earth.

The identity of lightning with electricity, though it had been previously suspected, was first directly demonstrated by the celebrated Dr. Franklin, in the year 1749, by the experiment of drawing sparks from the string of the electric kite. Since that time the science of electricity has been greatly advanced; nevertheless, the cause of some of the appearances connected with lightning is not well explained even at the present day.

The phenomenon of lightning is exhibited under two forms called respectively *forked lightning* and *sheet lightning*. The lightning is forked when the electric discharge occurs within a few miles of the earth's surface, and when it is directly seen by the observer. When, however, the discharge takes place below the horizon, or behind a dense cloud, only the scattered light reflected from the surfaces of the clouds illumined by the flash reaches the eye of the observer; the actual flash is not seen, but only the general illumination of a portion of the heavens. Such lightning is termed *sheet lightning*; and when the discharge takes place below the horizon or behind a very remote cloud, the distance is too great for the accompanying thunder to be heard. Sheet lightning may also sometimes be due to the electric discharges taking place at great elevations above the earth's surface. The more rarefied the air through which the electric spark passes, the less narrow and defined is its path. When the rarefaction is extreme, the discharge assumes the character of the *Aurora borealis*; but in somewhat more dense regions of the atmosphere its appearance would resemble that of the peculiar kind of sheet lightning which is observed when the sky is free from clouds. Forked lightning is produced by the intense ignition of the particles of air lying in the path of this electric discharge, and is generally of a reddish tint, which is due to the pink light emitted by the

LIGNIN

nitrogen of the air when heated to incandescence. [ELECTRICITY.]

Lightning Conductor. The early researches of electricians demonstrated that the effects produced by the passage of lightning through different substances varied greatly according to the nature of the substance traversed. Thus, its passage through a good conductor, such as a bar of metal, of sufficient sectional area, was found to produce only a slight elevation of temperature in the metal, whilst on the other hand its transit through imperfect conductors, such as wood, stone, &c., was attended with great heat and destructive mechanical effects, by which such imperfect conductors were torn to pieces, and, if combustible, ignited. This knowledge of the effects of the disruptive electric discharge led to the invention and adoption of the lightning conductor, which consists of a rod of metal, or series of rods placed in metallic contact, and extending from the earth to some distance above the highest point of the building or ship which it is designed to protect. The upper extremity of the conductor should be pointed, in order to convert, as far as possible, the ordinary spark or globular discharge into the less instantaneous brush discharge, and every prominent angle of the roof of a building should be furnished with its own pointed rod carefully connected with the main rod which descends to the earth. The latter should have its lower extremity carried to some distance from the foundations of the building, and low enough to reach moist earth; or, better still, it may be connected with a gas or water main. According to Sir J. Snow Harris, a copper rod three-quarters of an inch in diameter is a sufficient and safe conductor for any stroke of lightning ever recorded. Usually a much smaller rod would doubtless suffice.

Lign Aloës (Lat. *lignum aloës*, the wood of the aloë). The fragrant wood of *Aloezylum Agallochum*.

Ligneous (Lat. *lignum*). In Entomology, a part is so called when it is composed of a hard inelastic substance like wood.

Lignin (Lat. *lignum*). This term has been applied to the pure woody fibre: it has also been called *cellulose*: its ultimate composition is represented by $C_6H_7O_5$, but a higher equivalent is better adapted to its combinations, and its most convenient formula is $C_{24}H_{20}O_{10}$; it belongs, therefore, to the class of compounds of carbon and water which includes starch, gum, sugar, and some other substances. The ordinary varieties of woody matter differ in colour and texture; but when freed from foreign matters, they leave a white translucent residue, insoluble in water, alcohol, and ether, and convertible, by sulphuric acid, into a substance having some of the characters of starch, and then into dextrine and sugar. Certain piths, linen, cotton, paper, and some other allied substances, are nearly pure cellulose. Weak acids and alkaline liquids, and a weak solution of chlorine, have scarcely any action on it, but they change,

LIGNIPERDOUS

combine with, or decompose it when concentrated, and some of these reactions are very important: when, for instance, clean linen or cotton rags are acted on by cold sulphuric acid, a magma is formed, which if immediately saturated by carbonate of baryta, or of lead, yields insoluble sulphates, together with soluble *sulpholignates*. These salts appear identical with those of the sulphoglucic or sulphosaccharic acid derived from the action of sulphuric acid on glucose. This magma is also blued by iodine. If it be much diluted and boiled, it yields dextrine, and ultimately glucose. - By this action of sulphuric acid upon paper, a useful material now known as *vegetable parchment* is obtained. It is prepared by steeping thick unazed paper in a mixture of equal parts of sulphuric acid and water, at a temperature of sixty degrees, then washing it well in cold water and drying it. It is translucent, tough, and nearly impermeable to water, forming a useful substitute for common parchment or vellum. [PARCHEMENT.] The action of nitric acid on lignine also gives rise to several curious and useful products which are elsewhere noticed. [GUN COTTON; PYROXYLINE.] The affinities of lignin for various other substances involve important considerations bearing upon the arts of dyeing and calico-printing, and upon the preservation of timber from decay and dry rot, which are also adverted to under separate articles. [DRY ROT; DYEING; TIMBER; WOOD.]

Ligniperdous (Lat. lignum, and perdo, I destroy). A term applied to insects which destroy wood.

Lignite. The varieties of brown coal which show distinct marks of having been formed of trunks of trees are conveniently separated from the rest under the name of *lignite*. On the Rhine, in the duchy of Nassau, are very large deposits of this kind, and in Styria near Grätz are others equally remarkable. The ash contained in lignite is generally very considerable, rarely less than 20 per cent. There is also much water, which can be removed by exposure, besides a large quantity of hygroscopic water. As all this must be got rid of before available heat is obtained for raising steam, lignite is not an economical fuel.

As distinguished from brown coal, the most remarkable lignites are those of the Rhine, and the best passages from the one mineral fuel to the other are seen in Styria.

All varieties of brown coal injure by exposure to weather; but lignite splits and tears, while brown coal of the best kinds falls to powder after a few months. These materials may both be kept somewhat longer if not exposed to the weather. Lignites are extensively used for fuel where nothing better can be had. [BROWN COAL.]

Lignone (Lat. lignum). A liquid which may be separated by distillation from commercial wood spirit. It has also been called *Xylite*.

Lignosulphuric Acid. An acid resulting from the action of sulphuric acid upon lignine. It is more properly termed *Sulpholignic acid*.

LILIACEÆ

Lignum Vitæ (Lat. wood of life). The wood of *Guaiacum officinale*. [GUAIAIACUM.]

Ligula (Lat.). In Botany, a membranous appendage at the apex of the sheathing petiole of grasses, and analogous to the corona of some Silenaceous plants. The term *ligula* is also applied to certain bodies proceeding from the base, and alternate with the horns, of the organ called the *orbiculus* in Asclepiadaceous plants.

LIGULA. In Entomology, a name applied by Latreille to the lower lip of insects, or *labrum* of English entomologists.

Ligule (Lat. ligula). In Botany, the strap-like radiant florets of certain Composites. In a part of the order the ligulate florets are confined to the circumference; but in another group, the *Ligulifloræ*, they occupy the whole flower-head.

Ligulifloræ (Lat. ligula, and flos, a flower). That division of *Compositæ* in which the florets are all ligulate, and equivalent to the *Cichoraceæ* of Jussieu.

Ligure. The name of a stone mentioned as worn in the breastplate of the Jewish high priest (Exodus xxviii. 19). It was, probably, the same as the Jacinth or Hyacinth of the moderns.

Ligurite (so called after Liguria, the country where it is found). A variety of Spheene, of an apple-green colour, found in a talcose rock on the banks of the Stura in the Apennines. It resembles Chrysolite, but is considered superior to it as a gem, in colour, hardness, and transparency.

Ligustrin (Lat. lignum). A bitter principle found in the *Ligustrum vulgare*.

Ligustrum (Lat.). The genus of the Privet, a family of *Oleaceæ*, much grown in gardens, as ornamental evergreen or subevergreen shrubs. The Common Privet, *L. vulgare*, is much used for making hedges, and its purplish-black berries are said to be used amongst others for colouring inferior port wine.

Lilac. The *Syringa vulgaris* of botanists.

Lilac Stone or Lilalite. [LEPIDOLITE.]

Lilacine. A bitter crystallisable principle contained in the leaves of the *Syringa vulgaris*. It has also been termed *Syringine*.

Liliaceæ (Lat. lilium, a lily). A large natural order of Endogenous plants, typical of Lindley's Liliæ alliance, with hexapetaloid hexandrous flowers, a superior ovary, and anthers which burst internally. They are familiarly known, in consequence of the Asparagus, the Lily, the Fritillary, the Harebell, the Star of Bethlehem, and many other common plants, forming a part of the order; which differs from *Melanthaceæ* in having a single style, not three styles, and in the anthers opening towards the style, not towards the petals. The species are extremely varied. Some, like the Dragon-trees, form a tall woody perennial stem, which emulates that of palm-trees; others are small bulbous plants, whose stem only lives a few weeks. Almost all the order is sought after by cultivators of beautiful plants; and of the tulip and the hyacinth there are

innumerable varieties. Some Liliaceous plants secrete stimulating principles, which, in different degrees of concentration, give their activity to onions, garlic, chives, and similar garden productions, and medical value to squills.

Liliaceous. In Botany, a term invented by Link to denote a corolla the petals of which have their unguis gradually dilating into a limb, and standing wide by side. It is rarely employed.

Lilium (Lat.; Gr. *λίσσιον*). A genus of *Liliaceae* consisting of numerous beautiful flowers, which are great favourites in gardens. They are commonly called Lilies, and offer considerable variety of appearance. Several beautiful kinds are natives of Japan, the most glorious being *L. auratum*, with enormous white flowers spotted with rich red brown, and marked down each segment by a broad golden band. Some, as *L. crinum*, have long horizontal trumpet-shaped flowers; others, as the well-known White Lily, *L. candidum*, have the tube shorter, and the segments more rolled out; while others again, as *L. Martagon*, the Turk's Cap Lily, have the segments completely reflexed. In some countries the bulbous roots are eaten.

Lillite. A silicate of iron found at Przibram in Bohemia. It resembles Glauconite in appearance, and is probably a product of the decomposition of Iron Pyrites.

Lima (Lat. *a file*). A genus of Lamellibranchiate Bivalves, of the tribe *Ostracæ*, characterised by the length of their shells as compared with those of the nearly allied genus *Pecten*, and their more regular oval form. The ridges of the shell are most of them relieved with scales. The *Limas* swim with rapidity by means of their valves, but in a young state they secure themselves by means of a byssus.

Limacidae. [LIMAX.]

Limacina (Lat. *limax, a slug*). A genus of Testaceous Pteropodous Molluscs, existing in considerable numbers in the northern seas, and forming, with the *Clio borealis* and other small marine animals, the food of the whalebone whale. The body terminates in a spirally convoluted tail, and is lodged in a very thin shell, formed by one whorl and a half, umbilicated on one side and flattened on the other. The animal uses its light shell as a boat, and its wing-like fins as oars, and thus navigates in countless fleets the surface of the tranquil deep.

Limagon (Fr.). This name appears to have been given by Pascal to a certain curve of the fourth order and sixth class, whose form somewhat resembles a shell. It is generated from a circle by adding to and subtracting from all radii vectores through a point of its circumference a given constant length. Its polar equation, therefore, if a denote the radius of the circle and $2b$ the length added and deducted, is

$$r = 2(a \cos \theta + b).$$

In rectangular coordinates, its equation may be written in the form

$$[(x-a)^2 + y^2 - a^2 - 2b^2]^2 = 4b^2(b + 2\frac{a}{b}x),$$

whence we learn that the curve has a double point at the origin, two cusps at the circular points at infinity, a double tangent parallel to the ordinate axis at the distance $-\frac{b^2}{2a}$ from the

origin, and two points of inflexion. It belongs also to the class of Cartesian ovals, and includes the cardioid as a particular case corresponding to $b=a$. Just as the latter curve can be generated as an epicycloid, so the *limagon* may be generated as an epitrochoid, the rolling circle being taken equal to the fixed one.

Limax (Lat. *a slug*). The name of a genus of the Linnæan *Vermes Mollusca*, of which the common slug is the type. The genus enters into the class *Gasteropoda* and order *Pulmonaria* of the system of Cuvier; and is now raised to the rank of a family (*Limacidae*), which includes *Limax* proper; *Arion*, Fér.; *Inciliaria*, Benson; *Testacella*, Lam.; *Parmacella*, Cuv. &c. Each of these genera has a small scutiform rudimental shell developed in the substance of the mantle, and protecting the heart. The orifice of respiration in the true slugs (*Limax*, Cuv.) is on the right side, and not so far forward as in *Arion*. The rudimental shell is marked with fine and concentric striæ, and is calcified internally. The species of this genus are the pests of gardens and cultivated grounds. Young plants may be protected from slugs by having a coarse horsehair rope coiled round their stems, or by being plentifully sprinkled with soot; or they may be watered morning and evening with strong and fresh lime water.

Limb. In Astronomy, the border or outermost edge of the sun, moon, or of a planet. Also the graduated edge of a circle, or other astronomical instrument.

Limb or **Limbus** (Lat. *a border*). In Botany, a term applied to petals, to denote that portion which is supported by the unguis or claw; it is the same organ in a petal as the lamina in a leaf, and is what constitutes the broad thin coloured part which renders many flowers so beautiful.

Limbellite. An altered form of Chrysolite, occurring in small wax or honey yellow masses, in the basalt of Limbourg.

Limber (of uncertain derivation; possibly connected with limp, Swiss lampen, to hang loose; Wedgwood). In Artillery, a two-wheeled carriage, carrying ammunition boxes, to which the trail of the gun carriage is attached, when the latter has to be moved. It thus forms with the gun carriage a four-wheeled carriage. To *limber up* is to attach the gun to the limber.

Limber Strakes. The planking of a ship's internal skin, above the floor timbers, and next, horizontally, to the limbers. They are among the thickest of the planks used.

Limbers. In Shipbuilding, the main drains of the vessel. They are gutters running along each side of the keelson, receiving the hose of the pumps, and all the internal drainage of the

LIMBO

vessel. They are emptied from time to time by the pumps.

Limbo (Lat. *limbus*, a *hem* or *edge*). A region supposed by some of the schoolmen to lie on the edge or neighbourhood of hell. This served as a receptacle for the souls of just men, not admitted into purgatory or heaven. Such were, according to some Christian writers, the patriarchs and other pious ancients who died before the birth of Christ: hence the limbo was called *limbus patrum*. These, it was believed, would be liberated at Christ's second coming, and admitted to the privileges of the blessed in heaven. This latter idea is probably an adorned representation of the remarkable passage in St. Peter's Epistle (1 iii. 19), where he says that Christ preached to the spirits in prison; and being held by certain of the later fathers, seems to have given some influence to the growing opinion in favour of a purgatory. Dante has fixed his limbo, in which the distinguished spirits of antiquity are confined, as the outermost of the circle of his hell. The use which Milton has made of the same superstitious belief is well known. (*Paradise Lost*, book iii.) The analogous term, *limbus puerorum*, was applied to the abode of children dying unbaptised before the commission of mortal sin. It is described as a neutral state, without actual happiness or torment. Some of the fathers held, however, a less merciful doctrine. In one of his sermons against Pelagius, Augustine declared that such infants descended into everlasting fire, while Fulgentius maintained that even children dying before birth must be punished by the eternal torture of undying fire. (Lecky, *Hist. of Rationalism in Europe* i. 397.)

Lime (Ger. *leim*, *glue*). This very useful earth is obtained by exposing chalk and other kinds of limestone, or carbonates of lime, to a red heat—an operation generally conducted in kilns constructed for the purpose; the carbonic acid is thus expelled, and lime, more or less pure, according to the original quality of the limestone, remains. In this state it is usually called *quicklime*. Its specific gravity is about 3. When sprinkled with water it becomes very hot, and crumbles down into a dry powder, called *slaked lime*, or *hydrate of lime*. When exposed for some weeks to the air, it also falls into powder, in consequence of the absorption of moisture and of a portion of carbonic acid from the atmosphere; so that, in this case, part of the lime gradually reverts to the state of carbonate, and loses its causticity.

Pure lime may be obtained by heating powdered Carrara marble to whiteness in an open crucible. It is white, very infusible, but promotes the fusion of some other earths and oxides, and is therefore used as a *flux* in several metallurgical processes. It is highly luminous when intensely heated, as for instance by the oxy-hydrogen blowpipe. [DRUMMOND'S LIGHT.]

Lime is soluble in about 700 parts of water, and is somewhat more soluble in cold than in hot water. But, weak as this solution is, its action is powerfully alkaline upon vegetable

LIME

colours, and has an acrid taste. It absorbs carbonic acid by exposure to air; and as *carbonate of lime* is insoluble in water, it becomes milky in consequence; so that lime-water is a useful test of the presence of carbonic acid.

The nature of lime was first demonstrated by Davy in 1807: he showed that, like the other alkalies, it was a metallic oxide. The metallic base of lime has been termed *calcium*: its equivalent is 20, and lime, being a compound of one atom of calcium and one of oxygen (CaO), is represented by the equivalent 28; and hydrate of lime by 28 lime + 9 water = 37.

The *salts of lime* are generally obtained by dissolving carbonate of lime in the respective acids: several of them exist native. *Sulphate of lime* (CaO, SO₃), selenite, or gypsum, is an abundant natural product, and may be formed artificially by adding sulphuric acid, or the soluble sulphates, to solutions of the salts of lime. It consists of 28 lime + 40 sulphuric acid, and its crystals include two atoms = 18 of water. When these crystallised sulphates of lime are heated, they part with their water and fall into a white powder, called *plaster of Paris*; when this is mixed with water it again combines with it, and concretes into a white mass; hence its use for casts, busts, &c. Sulphate of lime is often contained in spring water, which is thus rendered *hard* and unfit for washing. These waters become turbid upon the addition of a spirituous solution of soap. *Phosphate of lime* (3CaO, PO₅) is found native, constituting the mineral called *apatite*. The *earth of bones* is also chiefly a similar phosphate of lime. *Oxalate of lime* is very insoluble, and is precipitated whenever oxalic acid or a solution of an oxalate is added to solutions containing lime; hence it is that *oxalate of ammonia* is so valuable a test of the presence of lime, and is frequently used for the purpose of separating lime in analysis. When oxalate of lime is well dried, at 500°, it is anhydrous, and consists of 28 lime + 36 oxalic acid = 64 oxalate of lime. This substance is occasionally found in the human urine, and sometimes forms calculi: these are often of a reddish brown colour and a rough exterior, whence they have been termed *mulberry calculi*. When hydrate of lime is exposed to chlorine, the gas is absorbed, and a *chloride of lime* is obtained. This article is manufactured upon an extensive scale, under the name of *bleaching powder*, and consists of about 33 per cent. of chlorine and 67 of hydrate of lime. It evolves chlorine when acted upon by acids; and gives it out very slowly when exposed to air, in consequence of the absorption of carbonic acid. It is a most useful disinfecting material, and when dissolved in water forms *bleaching liquid*. *Carbonate of lime* (CaO, CO₂) is thrown down when alkaline carbonates are added to solutions of the salts of lime. It is a most abundant natural product, and is found pure in the varieties of calcareous spar and statuary marble. Chalk and several varieties of limestone are also nearly pure carbonates of lime. It is easily

LIME

distinguished from other minerals by effervescing in dilute acids and by yielding quicklime when a fragment is heated before the blowpipe. It is constituted of 28 lime + 22 carbonic acid: the equivalent, therefore, of carbonate of lime is 50. [LIMESTONE.]

The uses of lime are very numerous. Its most important application is in the manufacture of mortar and other cements used in building. It is also very extensively used as a manure to fertilise land.

Lime (so called from the glutinous juice of the young shoots: the word is the same as Ger. *leim*, Lat. *limus*, Eng. *slime* and *loam*). The name of the Linden-tree, *Tilia europæa*, which, however, is by some authors said to be more correctly Lime-tree, from its bark or bast being used to make cordage. The name is also applied to certain fruits of the *Citrus* family, related to lemons and citrons. The varieties of *Citrus Limetta* are called sweet limes; and some varieties of the lemon, *C. Limonium*, are also popularly called limes. The fruit, like that of the lemon, is used for its acid juice.

Lime Burning. Although all carbonates of lime may, by burning, be brought to the state of quicklime, chalk and compact limestone are alone used for this purpose in the large way. The limekiln at present almost universally employed in this country is a cup-shaped concavity, in a solid mass of masonry, open at top and terminated at bottom by a grate, immediately above which is an iron door. This simple furnace is first charged with fuel (either wood, or coal and cinders), upon which is afterwards laid a stratum about a foot thick of chalk or limestone, broken into pieces not larger than the fist; to this succeeds a charge of fuel, and so on alternately, keeping the kiln always full. The pieces of limestone descend towards the bottom of the kiln in proportion as the fuel is consumed, being in the meantime kept at a pretty full red heat. At this temperature, the water and carbonic acid are driven off; and by the time the limestone arrives at the bottom of the kiln, which happens in about forty-eight hours, it is rendered perfectly caustic. The door above the grate is then opened, and the lime below the next descending stratum of fuel is raked out; the remaining contents of the furnace sink down, and a fresh charge is laid on the top. The compact limestone, after having undergone this process, though lighter and more porous than before, still retains its figure unaltered; hence it is readily separable from the ashes of the fuel, and is sufficiently hard to be carried from place to place without falling to pieces. The management of the kiln as to temperature varies with the nature of the limestone, which if silicious and overheated is apt to be partially vitrified; such lime slakes imperfectly, leaving a *opre*, and is said to be *dead-burnt*.

Attempts have been made to burn lime, or, in other words, to expel the carbonic acid from limestone, in close vessels, but the carbonic acid cannot be so driven off.

LIMESTONE

Lime Light. [DRUMMOND'S LIGHT.]

Limestone. Stone consisting chiefly of uncrystallised carbonate of lime. Perfectly crystallised carbonate of lime is *calc spar* or *Island spar*. Imperfectly crystallised carbonate of lime with a fine grain, or with the texture of sugar, is called **MARBLE** [which see]. Carbonates of lime and magnesia are described as **MAGNESIAN LIMESTONES**.

Compact limestone is sometimes white and nearly pure, sometimes coloured with iron or other metallic oxides, and often mixed irregularly with clay and sand. It passes by insensible gradations into impure limestone, marlstone, calcareous clay, and marl.

Limestones of all kinds are found in rocks of all geological ages; but it is generally fancied that the more crystalline varieties occur with the more ancient or the more distinctly metamorphic rocks. Thus in England the carboniferous limestones pass into marble. In the Alps, however, the oolitic rocks, and in the Carpathians cretaceous rocks, assume this form, and not unfrequently even tertiary rocks are altogether crystalline. On the other hand, the Silurian limestones are mere mudstones, and quite uncrystalline, so that there is no real law on the subject.

Whenever limestones are not distinctly metamorphic, they bear traces of organic structure. This is so much the case as to justify the assumption by geologists that all limestone is the result of organic action at some period or other. The indication of life is of various kinds, often microscopic. Corals, shells, and even bones make up in some cases the entire mass of large deposits. In other cases the limestone consists of minute particles of such bodies so cemented and combined into a solid, that it is scarcely possible without minute investigation to discover the secret. Shelly limestones of the oolitic period, such as are common at Bath and Portland Island, afford good examples of the first, and chalk of the latter condition.

Limestones are extremely useful, and therefore it is very important to discover them in every country. Of themselves, when in sufficient abundance, they generally make excellent building material. When not so used, they may be burnt to produce lime, either to work up into mortar, or employed for agricultural purposes. Forming part of a soil, the disintegrated fragments that are loosened from the rock below often mix with clay and produce useful soils during their slow decomposition. Worked up into the soil in a powdery state, they form marls and other useful admixtures.

In England the limestones are of four kinds: compact limestones, passing into marble of the carboniferous and Devonian period; oolitic limestones; mudstones, or impure clayey limestones, and marlstones, from both of which hydraulic cement is made; and chalk. The Silurian limestones are, for the most part, mudstones; the lias yields marlstone; and the rest belong to the middle and upper part of the

LIMIT

secondary period. There are in England no limestones belonging to the tertiary period, but they are abundant and excellent in the rocks of this date in the Paris Basin.

There is no necessary resemblance between the contemporaneous limestones of different countries; for of all deposits, limestones are those which are least persistent as mineral types of geological periods. Thus Silurian limestones in the north-east and north of Europe are semi-crystalline; the oolitic, or, as they are there called, Jurassic, limestones of the Alps are compact; the cretaceous limestones of the Caucasus are marble; and the tertiary rocks of the Paris Basin are calcareous, and afford excellent building material.

There are many local names for varieties of limestone. Some are called RAG STONE, others are FLAG STONES. CHALK is a well-known variety, and hard chalk is called CLUNCH. We have STONESFIELD SLATE, CEMENT STONE, SEPTARIA, KENTISH RAG, FOREST MARBLE, SUSSEX MARBLE, KELLOWAYS ROCK, MARLSTONE, and many others, all more or less distinct. Most of these will be found briefly described under their respective heads.

Limit (Lat. *limes*, *limitis*). In Mathematics, a given or determinate quantity to which some other variable quantity continually approaches in value, but never reaches. Thus, if we suppose a polygon to be inscribed in a circle, by increasing the number of sides of the polygon its area is increased. But the area can never exceed that of the circle within which the polygon is inscribed; and it is only when the number of its sides is conceived to be infinitely great that its area becomes equal to that of the circle. The circle is thus said to be the limit of the areas of the inscribed polygon.

Again, the limit to which $(1 + \frac{m}{n})^{nx}$ approaches as n is continually increased is e^{mx} , where e denotes the number 2.7182818 . . . known as the base of Napierian or natural logarithms. This important theorem is expressed thus: $\lim. (1 + \frac{m}{n})^{nx} = e^{mx}$.

One of the most satisfactory ways of establishing the principles of the differential calculus is by the consideration of *limits*. This was done by D'Alembert, though his *method of limits* coincides practically with that of *prime and ultimate ratios* employed by Newton in his *Principia*.

The *limits* of a definite integral are the values of the independent variable which correspond to the extreme terms of the series whose sum that integral represents. [DEFINITE INTEGRAL.]

Limitation. In Law, this term is generally used to express the time allowed by statutes for the commencement of litigation after the act complained of. The period beyond which personal actions of trespass, or debt on simple contract, cannot be brought, is defined by the stats. 21 Jas. I. c. 16 and 19 & 20 Vict. c. 97. They must be commenced within six years after the cause of action;

LIMNÆUS

with the exception of actions of assault, menace, and imprisonment, which are limited to four. But a right of action may be revived by an express acknowledgment on the part of the debtor.

Penal actions for forfeitures made by statute must be sued in general, according to the terms of the statutes, within two years or one year.

By the statute 3 & 4 Wm. IV. c. 27, all process for the recovery of land by entry and distress, or by action, whether real or mixed, must be commenced within twenty years after the right of action accrued. Persons under the disabilities of infancy, coverture, idiotcy, lunacy, unsoundness of mind, or absence beyond seas, are allowed ten years after the termination of their disability; so that forty years be in all cases the extreme limit. This statute extends both to suits in equity and actions at law. No ad-vowson can be recovered after one hundred years. Money charged upon land, and legacies, are deemed satisfied at the end of twenty years unless there have been some receipt or acknowledgment; and by stat. 23 & 24 Vict. c. 38 the same rule is extended to claims by the next of kin of intestates. Arrears of rent, or interest of money charged on land, cannot be recovered after six years, unless secured by bond or covenant, when by statute 3 & 4 Wm. IV. c. 42 actions may be brought at any time within twenty years after the cause of action has accrued. The various limitations in proceedings arising out of bankruptcies are defined by the bankrupt Acts. These are among the principal instances of legal limitation; but there are many more: a tabular arrangement of all will be found in Wharton's *Law Lexicon* (1860).

The statutes of limitation apply to equitable remedies directly, and by the plain import of the statutes, where the equitable remedy is sought (as it may be in some cases) for a right enforceable at law; and they have been adopted by analogy in those cases where a purely equitable right is the counterpart of a legal one, as the right to mesne profits in respect of an equitable ownership, or a debt payable in equity but not in law. Where there is not this strict correspondence between the equitable and legal claims, the rule prevails that twenty years' adverse possession, which is in law a bar to the possessory action for land, shall be a bar to all equitable claim, whether the adverse right be merely equitable also or equitable and legal; such period of limitation being, as at law, capable of extension from infancy, absence, or disability. But time is not a bar to the claim of cestui que trust against his trustee, where the trusteeship was in the origin direct and express, and not coupled with any beneficial interest, as it is in the case of a mortgage; nor does a purchaser, with notice from a trustee, stand in a better situation in respect to time than the trustee himself.

Limnæus (Gr. *Λιμναῖος*, from *λίμνη*, a pool). A genus of fresh-water snails; so named from their general location in ponds, ditches, and other receptacles of stagnant water. Many species of this genus are natives of Britain.

LIMNING

Limning (Lat. *lumen*, *light*). Illuminating. The art of painting in water colours; in which sense it is used to distinguish it from painting in oil colours. The term was originally applied to the decoration or illumination of MSS.

Limosin. A bitter crystalline matter found in lemon and orange pips.

Limonite (Gr. *λεῖμωρ*, *a meadow*). In Mineralogy, Brown Iron-ore. It is a hydrated peroxide of iron.

Limosa (Lat. from *limus*, *mud*). A genus of wading birds, belonging to the tribe *Longirostres*; and characterised by a straight beak, longer than that of the snipes (*Scolopax*), and sometimes slightly bent at the extremity; the nasal groove extends close to the tip, which is blunt and somewhat depressed; there is no third groove or punctation on its surface. The external toes are palmated at the base: they are longer and slenderer than in the snipes. The species of *Limosa* which, with us, are vernacularly termed Godwits, frequent salt marshes and the seashore.

Limosis (Gr. *ἄλγος*, *hunger*). A genus of diseases distinguished by excessive or defective appetite.

Limpets. [PATELLOIDS.]

Limulus (Lat. *limus*). A genus of gigantic Entomostracous Crustacea, in which the haunches of the first six pairs of feet are beset with small spines, and are so closely approximated about the mouth as to serve the office of jaws. The œsophagus, instead of proceeding backwards, is continued forwards for a short distance into the anterior part of the shield before it enters the stomach; this cavity is lined with a thick rugous cuticle, and terminates in the intestine by a long muscular and valvular projection. The heart is elongated, vasiform, and muscular; the branchiae are supported on a series of closely packed broad plates beneath the post-abdomen. The total number of feet is twenty-two: the first ten, with the exception of the two anterior ones in the males of some species, are terminated by a didactyle forceps, and are inserted, with the two following pairs, beneath a large semilunar shield. The species of this genus are found on the shores of the North American and Asiatic continents: they are commonly known by the names of king crabs, horse-shoe or mollusca crabs. The tail is long, straight, sharp-pointed, and of sufficient strength and size to be used as a spear-head or arrow-point by savages.

Linaceæ (Linum, one of the genera). A small natural order of herbaceous Exogens, principally inhabiting Europe and the North of Africa; allied, according to De Candolle, to *Sileneæ*, *Malvaceæ*, and *Geraniaceæ*. The want of a gynobasic structure, the imbricate calyx, the regular flowers, and the small quantity of albumen in the seeds, rather point out an affinity with *Cistaceæ* and its allies. Their chief characters are the tenacity of their fibre, the mucilage of their seeds, and the beauty of their flowers. Common flax or lin (whence linseed) is the most important plant of the order.

LINE OF DEFENCE

Linarite or **Cupreous Anglesite**. Native cupreous sulphate of lead often forming twin crystals of a deep azure-blue colour at Linares in Spain; also in Cumberland, at Leadhills in Lanarkshire, &c.

Lincolnte. A variety of Heulandite from Durdfield in Massachusetts.

Linctus (Lat. from *lingo*, *I lick*). A medicinal preparation of the consistence of thick syrup, or honey, which requires to be licked off the spoon.

Lindackerite. A hydrated arsenite of copper with sulphate of nickel, of a verdigris or apple green colour, occurring at Joachimsthal in Bohemia. Named after the Austrian chemist, Lindacker.

Linden-tree. The Lime-tree, *Tilia europæa*.

Lindsayite or **Linseite**. A hydrated variety of Amphodelite from Finland; the result, probably, of partial alteration.

Line (Fr. *ligne*, Lat. *linea*). In Fortification, any extended defence; as a ditch with its parapet, a row of gabions, &c.

LINE. In Geography and Navigation, is used for the equator: as equinoctial *line*.

LINE. In Geometry, a magnitude having only one dimension. Euclid defines it to be 'that which has length without breadth.'

LINE. In Military affairs, a term used to distinguish what may be called the regular cavalry and infantry of Great Britain from other military corps or establishments. All numbered cavalry and infantry regiments except the life guards, foot guards, and dragoon guards, belong to the *line*.

Troops are said to be *in line* when their formation, is of considerable frontage but little depth, as opposed to *column*. [COLUMN.]

Line of Battle. The line formed by the ships of the fleet when ranged ahead and astern of each other, at equal distances, and close-hauled or nearly so. It could be formed accordingly upon either tack. The line was composed of ships of not less than two decks, thence called *line-of-battle ships*. The invention of steam, and the introduction of long-range guns, with iron-sided ships, and their adaptation as rams, render it probable that in future the line of battle will give way to rapid evolutions by which the vessels will seek to outmanœuvre each other.

Line of Bearing. The line of bearing is formed by the ships of the fleet when ranged on a line six points from the wind, at equal distances, and with their heads in any direction whatever. The line is called by the name of that tack upon which if the ships were to haul to the wind together they would form the line ahead. For example; suppose the wind N., and the ships in a line W.N.W. and E.S.E. of each other; this is the *starboard* line of bearing, whether the ships are going free, or close-hauled upon the *port* tack.

Line of Curvature. [CURVATURE.]

Line of Defence. In Fortification, the line of the top of the scarp of any work re-

LINE OF DIP

criving flank defence; or that line together with its prolongation to the flanking work.

Line of Dip. In Geology, the strata which form the crust of the globe are rarely horizontal, but incline to some point of the horizon, and rise to the opposite point; a line drawn through these points is called the line of their dip.

Line of Fire. In Gunnery, the line formed by the axis of the piece produced. Whenever the gun is not laid point blank, the line of fire forms an angle with the line of sight. This is called the *angle of elevation*.

Line, Geodesic. [GEODESIC LINE.]

Line at Infinity. [INFINITY.]

Line of Least Resistance. In Military Mining, the line drawn from the centre of the charge perpendicularly to the surface.

Line of Metal. In Gunnery, a visual line, joining the notches cut on the highest point of the breech and muzzle when the trunnions are perfectly horizontal.

Line of Metal Elevation. In Gunnery, the elevation due to the conical form of a gun; when the gun is laid on an object by the line of metal.

Line of Nodes. In Astronomy. [NODES.]

Line of Operations. In Strategy, the line of communication from the original source of supplies or base of operations to the army.

Line of Sight. In Gunnery, the line passing through the two sights of a gun, at any elevation, and the object.

Line of Spherical Curvature. [CURVATURE, SPHERICAL.]

Lines. In Shipbuilding, the delineation of the form of an intended vessel supplied by the naval architect to the shipbuilder for his guidance in his work. They are the boundaries, on the ship's exterior, of vertical and horizontal planes passing through various parts. [NAVAL ARCHITECTURE.]

Lines of Circumvallation and Contravallation. [CIRCUMVALLATION; CONTRAVALLATION.]

Lineal Consanguinity. In Jurisprudence. [CONSAUQUINITY.]

Linear (Lat. linearis, from linea). In Mathematics, a term, of geometrical origin, applied in various (more or less technical) ways, but usually to magnitudes of one dimension or to functions of the first degree in a certain set of variables or facients. Thus a linear transformation is one where each variable is replaced by a function of the first degree in the new variables, and so in other cases. An expression involving two sets of variables is said to be *linear-linear* when it is of the first degree, whether considered as a function of one set or of the other. [TANTIPARTITE FUNCTION.]

Linear Differential Equation. An equation which is of the first degree when the expression equated to zero is regarded as a function of the dependent variables and its differential coefficients. It should be noticed that according to this definition a differential equation of the first degree is not necessarily

LINEAR DIFFERENTIAL EQUATION

linear. [DIFFERENTIAL EQUATION.] The general form of the latter is—

$$\frac{d^2y}{dx^2} + X_1 \frac{dy}{dx} + X_2 y = X,$$

$$+ \dots + X_{n-1} \frac{dy}{dx} + X_n y = X,$$

wherein the coefficients X_1, X_2 &c. . . , and the right-hand member X , are either constants or functions of the independent variable x . If the coefficients involved the dependent as well as the independent variable, the equation would be simply referred to as of the n^{th} order and first degree. The complete solution of a linear differential equation of the n^{th} order involving n arbitrary constants, can be readily deduced from any particular solution, provided the complete solution were known of the equation possessing the same coefficients X_1, X_2 , &c., but no second member, or rather if $X = 0$. In fact, if

$$y = F(x, c_1, c_2, \dots, c_n)$$

be the complete solution in the latter case, and $y = f(x)$ the particular solution, the complete solution of the above equation would be

$$y = f(x) + F(x, c, c_1, \dots, c_n).$$

When the coefficients of a linear differential equation are all constants, the calculus of operations enables us to express its solution in a very elegant form. In fact, separating the symbols of operation and quantity, such an equation may be written in the form

$$F\left(\frac{d}{dx}\right)y = X,$$

where F denotes a rational integral function of the n^{th} order. If, for the sake of an illustration, we suppose the equation $F(\xi) = 0$ to have n unequal roots a_1, a_2, \dots, a_n , and $\bar{F}(\xi)$, when resolved into partial fractions, to be equal to

$$\frac{A_1}{\xi - a_1} + \frac{A_2}{\xi - a_2} + \dots + \frac{A_n}{\xi - a_n},$$

then the solution of the above equation may be exhibited thus:

$$y = \left[F\left(\frac{d}{dx}\right) \right]^{-1} X = \sum_i A_i \left(\frac{d}{dx} - a_i \right)^{-1} X.$$

Now by the definition of inverse symbols of operation, we have, on representing

$$\left(\frac{d}{dx} - a_i \right)^{-1} X \text{ by } u,$$

$$\left(\frac{d}{dx} - a_i \right) u = X,$$

a linear differential equation of the first order whose complete solution is well known to be

$$u = e^{a_i x} \left\{ \int e^{-a_i x} X dx + C_i \right\};$$

so that the complete solution of the linear differential equation is

$$y = \sum_i A_i e^{a_i x} \left\{ \int e^{-a_i x} X dx + C_i \right\}.$$

LINEAR PERSPECTIVE

where C_1 is an arbitrary constant, and the summation \sum extends to the values $i = 1, 2 \dots n$.

For the modifications to be introduced when $F(\xi) = 0$ has equal, real or imaginary, roots, we must refer the reader to Prof. Boole's excellent treatise on Differential Equations (Cambridge 1859) or to his original memoir in the *Phil. Trans.* 1844.

M. Lobatto, in his *Théorie des Caractéristiques*, Amsterdam 1837, appears to have been the first to exhibit the solution of a linear differential equation with constant coefficients in the above form. For the full development of the symbolical method, however, we are chiefly indebted to Prof. Boole.

Linear Perspective. This name is applied to that branch of perspective which regards only the positions, magnitudes, and forms of the objects delineated; as distinguished from *aërial perspective*, in which the variations of the light, colour, and shade of objects, according to their different distances and the quantity of light that falls on them, are also considered and represented.

Linear Transformations. In Algebra, transformations whereby each one of a set of variables is replaced by linear functions of a new and equally numerous set. Geometrically, this is equivalent to the transformation of coordinate axes. Thus if x_1, x_2, \dots, x_n denote the original system of variables, and $\xi_1, \xi_2, \dots, \xi_n$ the new system, the transformations will be linear if the two sets are connected by relations of the form—

$$x_1 = a_{11}\xi_1 + a_{12}\xi_2 + \dots + a_{1n}\xi_n,$$

$$x_2 = a_{21}\xi_1 + a_{22}\xi_2 + \dots + a_{2n}\xi_n,$$

$$\dots \dots \dots$$

$$x_n = a_{n1}\xi_1 + a_{n2}\xi_2 + \dots + a_{nn}\xi_n.$$

The determinant formed from the coefficients,

$$D = \begin{vmatrix} & & & a_{1n} \\ a_{21}, a_{12}, & & & a_{2n} \\ & & & \dots \\ a_{n1}, a_{n2} & \dots & & a_{nn} \end{vmatrix}$$

is called the *modulus of transformation*, and when D is equal to unity the transformations are said to be *unimodular*. The theory of linear transformations plays a most important part in modern algebra. [INVARIANTS; CO-VARIANTS.]

By solving the above system of equations, we obtain the reciprocal transformations

$$D \cdot \xi_1 = A_{11}x_1 + A_{21}x_2 + \dots + A_{n1}x_n,$$

$$D \cdot \xi_2 = A_{12}x_1 + A_{22}x_2 + \dots + A_{n2}x_n,$$

$$\dots \dots \dots$$

$$D \cdot \xi_n = A_{1n}x_1 + A_{2n}x_2 + \dots + A_{nn}x_n;$$

when each coefficient A_{hi} is a *first minor* of the modulus of transformation; obtained, in fact, from the determinant D by omitting the i th column and h th row, and affixing the sign $(-1)^{h-1}(-1)^{i-1}$ to the resulting determinant of the $(n-1)$ th order. The modulus of the reciprocal transformations is easily shown to be

LINGUA FRANCA

equal to D^{-1} , so that the latter are unimodular when the original ones are unimodular.

Linens. A species of cloth woven with the fibres of the flax plant (*Linum usitatissimum*). The origin of the manufacture of linen is lost in its antiquity. In the time of Herodotus linen was an article of export from Egypt, where it had been used from time immemorial; but it is evident that in ancient times its use was limited to the noble and the rich. In modern times linen constitutes a staple manufacture in almost all European countries; but more especially in Germany, Russia, Switzerland, Flanders, England, Scotland, and Ireland. In England it has been prosecuted for a very long period; but until of late years its progress has been inconsiderable, compared at least with that made in other branches of manufacture. This seems to be partly owing to the attempts to bolster up and encourage the manufacture in Ireland, partly to the restrictions which were for a lengthened period laid on the importation of foreign flax and hemp, and partly to the rapid growth of the cotton manufacture—fabrics of cotton having to a considerable extent superseded those of linen. It is only within the present century that any machinery has been used in the production of linen cloth. The first mills for the spinning of flax were constructed at Darlington; but the principal seats of the manufacture now are—in England, Leeds and its immediate vicinity, and in Lancashire, Dorset, Durham, and Salop; in Scotland, Dundee, which indeed may be regarded as the chief seat of the British manufacture (*Geographical Dictionary*, art. 'Dundee'); and in Ireland, the province of Ulster. The entire value of the linen manufacture of Great Britain and Ireland is estimated at 14,000,000*l.*, and the total number of persons employed in it upwards of 200,000, a great impulse having been given to the manufacture by the dearth of cotton.

Ling. The *Calluna vulgaris* or Common Heather. The name is also given in China to *Trapa bicornis*.

Lino. In Ichthyology, the *Gadus Molva* of Linnæus; a species of cod inhabiting the northern seas. It is salted in large quantities.

Linga. The Hindu name for the emblem known as the Phallus among the Greeks. The Ashera, mentioned in the Books of Kings as set up in the house of Jehovah at Jerusalem, and translated *grove* in the authorised version, seems to have been an emblem of the same kind. [PHALLUS.]

Lingua (Lat. *a tongue*). In Entomology, the name of an organ situated within the labium or emerging from it, by which insects, in many cases, collect their food and pass it down the pharynx, which is situated above its root.

Lingua Franca. The dialect spoken chiefly along the European and African coast of the Mediterranean. It is a species of corrupt Italian, mingled with words of other languages, and may be termed the Creole of the Mediterranean.

LINGULA

(Lat. dim. of *lingua*). A genus of Palliobranchiate Bivalves with two nearly flat, smooth, oblong, triangular valves, attached between the two apices to a long fleshy pedicle. The arms, or labial appendages, are spirally involutioned, as in the rest of the class.

Lingula Flaga. A group of deposits chiefly composed of coarse flag stones, but in all nearly two thousand feet thick, and remarkable as yielding an infinite multitude of specimens of a peculiar bivalve shell, the *Lingula*, whence the name of the deposit.

The Lingula flags, though certainly very old, are not the most ancient rocks within the compass of the British Islands. They belong to the middle member of the lower Silurian series overlying the Harlech grits. They have sometimes been called *Cambrian*, as occurring in the district once known as Cambria; but they are not sufficiently distinctive as a group to justify the name.

(Lat. *linimentum*, from *linio*, *I besmear*). A semi-fluid ointment, or a soapy application, to rub upon painful joints. The term is also applied to spirituous and other stimulating applications for external use.

Linnaea. A bitter principle obtained from the *Linum catharticum*, or purging flax.

Lining. In Architecture, any covering of an interior surface. The linings, for instance, or boxings of window shutters, are the pieces forming the backs of the recesses into which the shutters are folded. In doorways, they are the facings on each side of the aperture; to sashes, they are the vertical pieces parallel with the surface of the walls. In Engineering, linings are sometimes applied to prevent the radiation of heat from the surface of a cylinder or steam pipe.

Links (Swed. *länk*, a *ring*: Wedgwood). Short connecting pieces in a steam engine, with bearings at both ends, for transmitting motion from one rod, or lever, to another. The link motion is an ingenious contrivance for working the slides, without a separate expansion gearing. [STEAM ENGINE.]

Linnean System. [BOTANY.]

Linnesite. Native sulphide of cobalt, in which the cobalt is sometimes partly replaced by nickel or copper. It was first noticed in Sweden by Linneus, and named after him.

Linnet. The *Fringilla cannabina* of Linnaeus. A small song bird allied to the goldfinch and siskin. It is often confused with the Redpole (*Fringilla linaria*).

Linseed. The seed of the flax plant, *Linum usitatissimum*.

Linsenerz or **Linsenkupfer** (Ger.). Native octahedral arseniate of copper. [LIMONITE.]

Lint. A soft woolly material made by scraping old linen by hand; it is also made by machinery. It is used in Surgery for dressing wounds and ulcers, either alone or spread with some ointment.

Lintel (Fr. *linteau*). In Architecture, horizontal piece of timber, or stone, inserted

LINUM

over a door, window, or other opening, to discharge the superincumbent weight.

Linum (Gr. *λίον*). The genus of the Flax, the common Flax being *L. usitatissimum*. This is an annual with smooth erect slender stems, narrow pointed leaves, and blue flowers, and is largely cultivated for its fibre, which forms the linen of commerce.

Flax has been grown for its fibre from the earliest times of which we have any record. The books of the Old Testament afford ample proof of its antiquity as a material for weaving cloth; and representations of its culture occur in ancient Egyptian pictures which have come down to us. The plant was cultivated by the early Romans; but as their clothing was chiefly made of wool, it did not find much favour.

In modern times the culture of Flax is widely spread in the northern hemisphere, extending from the tropics in India and Egypt to the northern parts of Europe. The principal producing country, from which we obtain the greater portion of our supply, is Russia, flax being an important crop in the northern districts of that country; but large importations are likewise received from Belgium, Holland, Prussia, and other countries, in addition to which a considerable quantity is annually produced in our own country, mainly, however, in the north of Ireland.

The processes which flax undergoes before it reaches the hands of the spinner, vary in different places, but the general principle is the same in all, and although many new processes have been invented for shortening the time occupied by the various stages, none has yet entirely superseded the old modes. They may be said to consist of six operations: *Rippling*, or the removal of the seed capsules by drawing the stem through a kind of comb. *Steeping* or *watering*, the object of which is to facilitate the separation of the fibre from the wood, and to get rid of the mucilage. To accomplish this, the flax-straw is tied in bundles and placed in ponds or rivers, where it is allowed to remain for a period of eight to twelve days, when it is taken out, and then undergoes *grassing*, the bundles being untied and the straw spread out evenly and regularly on pasture land, and frequently turned so as to expose both sides to be washed and bleached by exposure to the rain and sun. Then follows *breaking*, by which operation the woody part of the stem is broken previous to *scutching*, which removes all the broken fragments left adhering after the last process. These two operations are generally effected by machinery, but were formerly performed by hand labour. After scutching, flax finds its way into the market, but before being used by the spinner it undergoes a sixth operation called *heckling*, which removes all extraneous matter and completely separates and arranges the filaments in parallel order. It consists in drawing the flax over sharp iron spikes arranged in a quincunx manner and inserted into oblong pieces of wood.

The seeds of the Flax plant, known as Linseed, are a commercial article of considerable importance, for the supply of our oil-mills. The finest kind of linseed oil is the product of simple pressure, and is called *cold drawn*; but the ordinary kind is obtained by breaking up, beating, and re-pressing the marc or cake left after the last process. It is a non-drying oil; but by boiling with sugar of lead, red-lead, or white vitriol, it is converted into a drying oil fit for the use of painters, by whom it is most extensively employed. The cake is greatly valued by agriculturists for feeding purposes; and in addition to that made in this country, large importations are received from abroad. [FLAX.]

Mr. Darwin has recently (*Journal of Linnean Society*, vii. 69) directed attention to the dimorphism which exists in the flowers of *Linum*, by which means they become functionally, though not structurally, unisexual.

Lion. *Felis Leo* (Linn.). The largest, most formidable, and most noble of the Carnivorous animals, though not the most typical of the genus *Felis*. It is chiefly distinguished by the presence of a full-flowing mane in the male, and by a tufted tail and the disappearance of the feline markings in both sexes before they arrive at maturity; the colour then being a nearly uniform light fulvous brown, with mane inclining to black, especially in the Central and South African races. The mane is scantier and lighter coloured in the Asiatic than in the African lions; and there exists a maneless variety in the eastern parts of Hindustan. [FELIS.]

LION. In Heraldry, a beast, of which the figure is very commonly borne as a charge. The attitudes in which the lion is represented are very various. [RAMPANT, PASSANT, REGARDANT, GARDANT, COUCHANT, SALIENT, SUIVANT.] A lion passant is termed, in French heraldic language, a *leopard*; and hence the common notion that the lions of England were substituted for leopards.

Lion Ant. [MYRMELION.]

Lion of England. A lion passant regardant or (being the bearing of England) is frequently thus termed in heraldry.

Lip (Lat. labium). A term applied to either of the two divisions of a monopetalous corolla, where one portion takes a direction upwards and the remainder a direction downwards, as in *Labiata*. It is the same as LABELLUM [which see].

Liparis (Gr. λιπαρίς, *glistening*, from λίπος, *fat oil*). The name of a genus of Lepidopterous insects; also applied by Pliny to a genus of fishes. In Botany, it is the name of a genus of plants of the Orchidaceous order.

Liparite. [FLUOR SPAR.]

Liparocoele (Gr. λιπαρίς, and κείλη, *a tumour*). A fatty tumour.

Lipic Acid (Gr. λίπος, *fat*). An acid formed by acting upon stearic and oleic acid, by means of nitric acid.

Litogrammatic Works or Writings (Gr. λίστα, *I omit*, and γράμμα, *a letter*). Compositions in which a particular letter is omitted throughout. The ancients produced many ingenious trifles of this description. In the *Odyssey* of Tryphiodorus there was no A the first book, no B in the second, and so on. There are other pieces of modern invention, such as the *Pugna Porcorum*, in which all the words begin with the letter P. Odes in Spanish, containing only one of the vowels, are refinements on the same invention.

Lipoma (Gr. λίπος, *fat*). An encysted fatty tumour.

Liporna (Gr. λίπος). A soft fatty tumour.

Lippitude (Lat. from lippus, *blear-eyed*).

The disease commonly called *bleared eyes*, consisting in a puriform exudation from the margin of the eyelids, which often causes them to adhere together after sleep.

Liquation. [ELIQUATION.]

Liquefaction (Lat. liquefactio). The act of melting or of fusing. This term is also used synonymously with *solution*.

Liqueurs (Fr.). This term is applied to a great variety of foreign compounded spirits. In France they are known as *ratifias* and *crèmes*: they are generally alcoholic solutions or tinctures, sweetened and variously flavoured. The varieties of *noyau* are flavoured with prussic acid and essential oil, derived from the bitter almond, peach and apricot kernels, and similar sources. *Maraschino* is prepared in Dalmatia from a cherry called *marasquin*, which is bruised, fermented, and distilled; its flavour is derived from the kernels of the fruit and some peculiar product of its fermentation, the alcohol being formed from its saccharine matter: the distilled product is afterwards sweetened, and sometimes coloured. *Curaçoa* is a tincture of orange berries and orange peel, cloves, and cinnamon, in old brandy, to which syrup is subsequently added. For *colourless curaçoa* the tincture is distilled, and the distillate afterwards sweetened. *Kümmel* (a favourite German liqueur or *schnaps*) is sweetened spirit of caraway. Tea, coffee, and innumerable other sources of flavour are resorted to. The celebrated *vermouth*, or *crème d'absynthe*, is an analogous preparation from wormwood.

Liquidamber. A balsam procured in Mexico and Louisiana from the stem of *Liquidamber styraciflua*.

Liquids. In Grammar, the letters *l, m, n*, and *r* are so called.

Liquor Amnii. The liquid contained in the membrane enveloping the fœtus of most mammiferous animals. It contains mucus, albumen, grape sugar, and the chlorides, sulphates, and phosphates of sodium and potassium in aqueous solution.

Liquor of Cadet. *Alcarnin* or *oxide of cacodyl*. A volatile and very poisonous liquid formed on heating arsenious acid with acetate of potash. It has an extremely disagreeable odour, and its vapour is a powerful irritant to the eyes and nose.

LIQUOR SANGUINIS

Liquor Sanguinis. [PLASMA.]

Liquor Siliolum (Lat.). Liquor of flints. A solution of silicated potash or soda.

Liquorice (Gr. γλυκύριζα, a plant with a sweet root). The extract of the root of the *Glycyrrhiza glabra*, or Official Liquorice: it is often called Spanish liquorice or Spanish juice, of which that stamped with the name Solazza, and imported in sticks or bars six or eight inches long, is considered the best. It is in common use as an emollient in catarrh and cough. The so-called *refined liquorice*, rolled into pipes or quills, is often much adulterated. [GLYCYRRHIZA.]

Litella. In Botany, a term used in describing lichens, to denote a linear shield, with a channel along its middle, as found in *Opegrapha*.

Liriodendrine (Gr. λειριον, a lily, and δένδρον, a tree). A bitter crystallisable principle obtained from the bark of the root of the *Liriodendron Tulipifera*, a handsome North American tree of the Magnoliaceae order.

Litroconite (from Gr. λειρός, pale, and κόνις, dust). A hydrated arseniate of copper, occurring crystallised in obtuse rectangular pyramids of a sky-blue or verdigris-green colour in Cornwall, at Huel Multrell, Huel Gorland and Huel Unity, and also in Hungary. The name has reference to the paleness of the streak yielded by the mineral, compared with its natural colour.

Lissencephala (Gr. λισσός, smooth, and εγκέφαλος, brain). The subclass of mammalia in which the *corpus callosum* is present, but connects cerebral hemispheres as little advanced in bulk or outward character as in the *Lycencephala*; the cerebrum leaves both the olfactory lobes and cerebellum exposed, and being commonly smooth, or with few and simple convolutions in a very small proportion of the largest members of the sub-class. It is composed of the orders BRUTA, CHEIROPTERA, INSECTIVORA, and RODENTIA [which see].

List (derived by Mr. Wedgwood from the lists or hangings with which the tilting yards were hung, and so connected with Dutch lijst, Ital. liccia, lizza, Span. liza, Fr. lices, lisse). The enclosed field or ground wherein the ancient knights held their jousts and tournaments. It was encircled with pales, barriers, or stakes. These were sometimes double, one for each cavalier, to prevent them from coming nearer each other than a spear's length. Hence the expression to *enter the lists* is synonymous with engaging in contest.

The term *lists* was also applied to the space between the exterior and interior line of defences in mediæval fortifications.

Liser. The name given to the border or selva of a piece of cloth, &c.

List, Civil. [CIVIL LIST.]

Listel or **List.** In Architecture, the same as fillet or annulet.

Listening Galleries or **Listeners.** In Military Mining, the most advanced galleries of a system of countermines; so called because

LITERATURE

from them the defenders can hear any advancing mining parties of the besiegers.

Listing. In Architecture, the process of cutting off the sappy part of a board is called *listing* it.

Litany (Gr. λητρεία, supplication). This term was applied by the Eastern church in early ages to a special form of prayer which was introduced into the ritual, or used on particular occasions. The term passed into the Western church, where the words *rogatio* and *supplicatio* had before been used in the same technical sense. It appears that some of the Eastern litanies contain the supplication to saints which forms a distinguishing feature of the Roman. The litany in the Book of Common Prayer of the Church of England is mostly translated from the forms of the Western litanies previously used in this country, namely those of the breviaries of Salisbury and York. (Palmer's *Origines Liturgicæ*, i. 264.)

Literary Property. [COPYRIGHT.]

Literati (Lat.). This word denotes, in general, learned men. In China such persons as are able to read and write their own language, and also a particular sect, consisting chiefly of the most learned men of that country, are called *Jukiao*, or learned. It is from the class of the literati that the MANDARINS [which see] are alone capable of being selected. In this country, the term is now applied chiefly to persons who are admitted into holy orders without having previously taken an academical degree.

Literature (Lat. *litera*, letters). This word denotes, generally, the entire results of knowledge and fancy preserved in writing; but, in the narrower use to which ordinary custom restricts it, we draw a distinction between literature and positive science, thus exempting from the province of the former one extensive branch of our studies. And, in a still more restricted sense, the word *literature* is sometimes used as synonymous with *polite literature*, or the French *belles-lettres*.

The history of literature is a peculiar and distinct subject, comprising several subdivisions, such as histories of the literature of special ages or countries; or histories of separate branches of literature, such as poetry. For its complete execution it requires a union of bibliographical knowledge with critical acumen. It should give the reader a sufficient acquaintance with the titles, contents, and dates of remarkable books, and with the general biography of remarkable authors, together with a critical appreciation of the characters and value both of authors and books, and of the dependence, connection, and derivation of literature; that is, the mode in which opinions, taste, and style have been propagated or changed. This last, as it is the most difficult part of the subject, is also that of which the execution has been hitherto most imperfect.

In the following brief notices of the principal works of general literary history which the student has it now in his power to consult, wo

LITERATURE

shall follow, in great measure, the criticisms of Hallam, in the Preface to his *Introduction to the Literature of Europe in the Fifteenth, Sixteenth, and Seventeenth Centuries*. The oldest work of this description (if such it can be called) is that of Polydore Virgil, *De Inventoribus Rerum*, 1499. Conrad Gesner, who has been termed the father of literary history, published his *Bibliotheca Universalis* at Zurich, 1645-56. Notwithstanding these and a few other meagre attempts, Lord Bacon, says Hallam, was justified in denying that, up to his time, any real history of letters had been written. The next in order of time is Lambuc's *Prodromus Historiæ Literariæ*, 1659; a work designed on a great plan, but scarcely begun. But Morhof's *Polyhistor Literarius*, first published in 1688, and much enlarged by subsequent editors, is still found in every considerable library. Andréa, a Spanish Jesuit, published his *Origine, Progresso, e Stato Attuale d'ogni Letteratura*, from 1782 to 1799; a very extensive, and, in some respects, valuable work, though without much display of taste, and no signs of genius. In the present century, no writers, except those of Germany, have attempted a field which has become of such enormous extent; but Eichhorn's *Literary History*, in six volumes, 1805, 1811, appears to be now, on the whole, the most complete and valuable work of this kind extant. Waehler's *Manual of Literary History*, in four volumes, appeared at Leipzig in 1833.

But besides these general compendia, much assistance is to be derived from general biographers. Of these the well-known dictionary of Bayle, first published in 1697, is the earliest of any value. That of Nicéron, *Mémoires pour servir à l'Histoire des Hommes illustres de la République des Lettres*, 43 vols. 12mo. 1733, 1746, is extraordinarily copious, and useful in biographical details, but in other respects of no great value. The *Biographie Universelle* (of which the original edition was in 52 volumes, and a supplement is now in course of publication which has reached the letter H) stands first among this class of works. Chalmers's *Biographical Dictionary* scarcely deserves mention as a literary work; but its historical details are sometimes minute and useful, though not unfrequently most so in the obscurest names.

Of partial works on literary history some of the most remarkable and useful are: 1. According to subjects—History of Philosophy, Brucker, Buhle, Tennemann (abridged by Victor Cousin). To these we may add, brief as they are, the Introductory Essays of Stewart and Playfair to the *Encyclopædia Britannica*. Of Belles-lettres generally, Bouterwek, 12 vols. 8vo. Poetry, Quadrio, *Storia d'ogni Poesia*; a work of remarkable industry, though strangely defective in point of critical taste. 2. According to countries—German: the works of Menzel, Vilmar, and others. English: Craik, *History of the English Language and Literature*. Arnold, *Manual of English Literature*. Taine, *Histoire de la Littérature Anglaise*. French:

LITHIUM

LaHarpe, *Cours de Littérature Française*; a performance of considerable, but in parts superficial and showy, talent. Italian: Tiraboschi, *Storia della Letteratura Italiana*; a work of extraordinary value, in which the history of Italian literature has been traced, with the greatest care and the most elaborate research, from the earliest times down to the last century. It has been abridged, but with some original criticism, by Ginguené, in his *Histoire Littéraire de l'Italie*; Corniani, *Secoli della Letteratura Italiana dopo il suo risorgimento*, 1804, 1813. Sismondi's *Littérature du Midi de l'Europe* is most valuable, also, in its Italian chapters, although those on Spanish and Portuguese literature touch on subjects less generally known. In England, Warton's *History of Poetry* contains much that bears on our general learning; but leaves us about the accession of Elizabeth. 3. According to ages: The work of Hallam, which comprehends the literary history of Europe from 1400 to 1700, is almost universal in its character. Its peculiar excellences are a philosophical spirit, manliness and candour of judgment, great honesty in the execution, and a taste unusually cultivated and correct.

Lithagogue (Gr. λίθουργός, *bringing stones*). Medicines supposed to have the power of expelling calculous matter from the kidney or bladder.

Litharge, Lythargyrum (Gr. λίθάργυρος, from λίθος, and ἄργυρος, *silver*; probably from its silvery appearance). Fused oxide of lead. [LEAD.]

Lithia (Gr. λίθειος, *of stone*). The oxide of lithium (LiO), an alkaline substance, discovered in 1818 by M. Arfwedson in a mineral called *petalite*; it has also been found in a few other lapideous bodies such as *lepidolite* and *triphanite*. It is distinguished from potassa and soda by the difficult solubility of its carbonate; from baryta, strontia, and lime, by the solubility of its sulphate and oxalate; and from magnesia by the alkalinity of its carbonate. It is the oxide of *lithium*; the equivalent of which is 7, and that of lithia 15. The salts of lithia impart a peculiar crimson-red colour to the flame. By spectral analysis traces of lithia appear to have been detected in sea-water, and in many mineral springs.

Lithia Mica. [LEPIDOLITE.]

Lithiasis (Gr. from λίθος). The disease of stone in the bladder or kidney.

Lithic Acid (Gr. λίθος). The substance generally termed *uric acid*: it forms the commonest variety of urinary calculus. [URIC ACID; CALCULI.]

Lithium (Gr. λίθος). This metal (represented by the symbol Li and the equivalent 7) has been obtained by the electro-chemical decomposition of its chloride: it is white, softer than lead, fusible at 356°, and volatile at a full red heat; it decomposes water. When heated in the air it burns with an intense white light, forming lithia. Lithium is the lightest known solid; its specific gravity being 0.539,

LITHOCHROMATICS

so that it floats upon naphtha. Carbonate of lithia has been used in medicine as a lithon- triptic, in cases of uric sand and gravel; it dissolves uric acid somewhat more freely than the carbonate of potash or soda. [LITHIA.]

Lithochromatics (Gr. λίθος, and χρώμα, colour). A term applied to painting in oil upon stone, and taking impressions upon canvas.

Lithocolla (Gr.). A cement for stone-work.

Lithodendron (Gr.). Coral has been thus designated, from its frequent arborescent appearance.

Lithodermis (Gr. λίθδερμος, with strong skin). A genus of Apodal Echinoderms, in the system of Cuvier; characterised by an oval body compressed posteriorly, of which the surface is covered with a layer of calcareous granules, which form an extremely indurated crust.

Lithodomes (Gr. λιθοδόμος, building with stone). This term is applied to those bivalves which are found in rocks and stones, inhabiting cavities, which they form for that purpose. A particular genus is called *Lithodomus*.

Lithofellic Acid (Gr. λίθος, a stone, and Lat. fel, gall). A substance obtained by Göbel from a Bezoar stone. In 1844, Taylor made the curious discovery of the identity of the substance constituting the so-called *Oriental Bezoars*, which are probably the intestinal concretions of a species of antelope, with the acid called *Ellagic acid*, contained, along with tannic and gallic acids, in the gall nut.

Lithographic Stone (Gr. λίθος, and γραφω, I draw). A limestone splitting into plates and slabs of moderate thickness, and having a sufficiently hard smooth and absorbent surface to be adapted for use for lithographic purposes. The best of such stones are from the upper oolites of Pappenheim and Solnhofen in the North of Bavaria. Very good stones are also obtained from the lias in many other parts of Europe, and some from beds of other geological periods.

Lithography. [ENGRAVING.]

Lithological (Gr. λίθος, and λόγος). A term expressing the stony structure or character of a mineral mass. We speak of the *lithological* character of a structure, as distinguished from its *zoological* character.

Lithomarge (Gr. λίθος, and Lat. marga, marl). Stone-marrow. A hydrous silicate of alumina of various colours, generally associated with magnesian minerals. The term has, however, been applied by mineralogists to several substances, some of which are mere products of the decomposition of other minerals.

Lithontriptics (Gr. λίθος, and τριβω, I rub away). Remedies which are supposed to dissolve stone in the bladder, or which prevent the deposition of calculous matter in the urine.

Lithontriptor. An instrument for breaking calculi in the bladder, so as to reduce them to small particles which may admit of being passed along with the urine, and thus render the operation of lithotomy unnecessary.

Lithophagi (Gr. λίθος, and φάγω, I eat). Molluscous animals which bore into stones. [LITHODOMES.]

LITURGY

Lithophytes (Gr. λίθος, and φυτόν, a plant). Polypes which have a stony axis; as distinguished from the Keratophytes, or horny polypes.

Lithornis (Gr. λίθος, and ὄρνις, bird). A genus of vulturine birds, of which fossil specimens are found in the Eocene clay at Sheppey.

Lithotomy (Gr. λιθοτομία). The operation of cutting into the bladder for the removal of a stone.

Lithotriety (Gr. λίθος, and Lat. tritus, part. of tero, I rub or wear away). The operation of breaking a stone in the bladder into small pieces capable of being voided by urine: it is effected by the introduction of instruments by the urethra, and under skilful management has in many instances successfully superseded the more formidable operation of lithotomy.

Litmic Acid. The chief constituent of the ordinary litmus of commerce.

Litmus. A blue pigment obtained from various lichens, among which species of *Rocella*, *Lecanora*, and *Variolaria* have been especially resorted to; it is often called *turnsol*, and yields the dye called *archil*. Paper tinged blue by litmus is reddened by the feeblest acids, and hence is used as a test of the presence of acids; and litmus paper which has been reddened by an acid has its blue colour restored by an alkali. Distinct colouring substances have been obtained from litmus, such as lecanorine, orceine, erythrine, &c. [LICHEN.]

Litotes (Gr. λιτότης, from λιτός, plain). In Rhetoric, a figure, according to the Greek and Latin rhetoricians, in which an affirmative is expressed by the negative of the contrary; it is, therefore, a species of irony in the ancient sense of the word [ΙΡΟΝΙΑ], in which less is expressed than what is intended to be conveyed to the mind of the reader or hearer. Thus, 'a citizen of no mean city' means 'of an illustrious city.' It is a figure constantly employed to soften what might otherwise appear obnoxious in self-commendation.

Litre. The French standard measure of capacity in the decimal system. The litre is a cubic decimetre; that is, a cube, each of the sides of which are 3·937 English inches: it contains 61·027 English cubic inches. Four and a half litres are a close approach to the English imperial gallon.

Littorina (Lat. littus, the seashore). A genus of Pectinibranchiate Molluscs of the tribe *Trochoida*; characterised by its thick shell, of which the aperture presents a small angle, and is without a ridge. The common periwinkle of our coasts (*Turbo littoreus*, Linn.) is a species of this genus.

Liturgy (Gr. λειτουργία). At Athens, certain public services, performed by the wealthier citizens, were called Liturgies. Among the ordinary liturgies were the Choregia, Lampadephoria, Hestiasis, &c.; the extraordinary liturgy was the Triarchia, or the duty of equipping and manning ships for the Athenian fleet. In later times these services, when too

expensive for one citizen, were performed by two, whose partnership was termed *Συττελεια*; the members in these partnerships for contributing ships was much larger; and such societies were also called *Symmoriae*. On the mismanagement of this service, and the reforms proposed by Demosthenes, see his oration *De Coronâ*. It is from this term that the English **LITURGY**, in its ecclesiastical meaning, has been derived; the sense having been contracted from public *ministry* or service in general to the ceremonies of religious worship.

LITURGY. The ritual according to which the religious services of a church are performed. In the writings of the ancients the name is restricted to the service of the Eucharist, which afterwards came to be distinguished in the Western church by the term *missa*, or mass.

There still exist in Greek, Latin, and some Oriental languages, various rituals according to which the Eucharist was celebrated in very early ages. Some have supposed that all these may be referred to one original liturgy, which may have been universally adopted in the primitive church. Palmer (*Antiq.* vol. i. p. 8) conceives that the number of original liturgies may be reduced to four, but not lower. These he entitles the great Oriental liturgy, the Alexandrian, the Roman, and the Gallican; each of which was extensively used from the apostolic age in the quarters from which he assigns them their names, and became the parents of many other rituals, such as were used, with many variations, in the different patriarchates of the empire.

The earliest period at which any liturgical forms were consigned to writing is the end of the third or beginning of the fourth century; at least the liturgy called of St. Basil can be traced as high as the latter period. This practice, also, seems frequently to have been applied only to certain parts of the service. We find, therefore, great differences in the MSS. which now exist; and it becomes very difficult to ascertain what the contents of the primitive rituals were, and to trace the periods at which many rites and ceremonies have been introduced into the service.

The liturgy of the church of England is a liturgy in the wider and more usual acceptation of the term, comprehending the whole of the various services used on ordinary and extraordinary occasions throughout the year. For the history of this liturgy, see **COMMON PRAYER**. See also Assemani, *Codex Liturgicus*; Muratori, *Liturgia Romana Vetus*; Breff's *Collection of Liturgies*; Palmer's *Origines Liturgicae*; Maskell's *Monumenta Ritualia Anglicana*.

LITUUS (Lat.). Among the Romans, a crooked staff, resembling a crozier, used by the augurs in quartering the heavens. The origin of the word is uncertain.

LITVUS. In Geometry, the name given by Cotes to a spiral, of which the characteristic property is that the squares of the radii vectores are reciprocally proportional to the angles which they respectively make with a certain straight line *OX* given in position,

and which is an asymptote to the spiral. The polar equation is obviously $r^2\theta = a^2$. It has a point of inflexion at A corresponding to the value $r = OA = a/\sqrt{2}$. For the properties of the lituus, see Varignon, *Mém. Acad. Paris* 1704; Cotes, *Harmonia Mensuratum*, p. 85; Peacock's *Examples in the Diff. and Integral Calculus*, p. 183 &c.

LIVER (A.-Sax. *lifere*, Ger. *leber*). The viscus in which bile is secreted. It is situated in the right hypochondriac region under the diaphragm; and in the human body is divided into two lobes, of which the right lobe is the largest. There is between them a smaller lobular process, called the *Lobulus Spigelii*. The ultimate arrangement of the different blood-vessels of the liver is very peculiar. It has been ably investigated by Mr. Kiernan, by whom it is described in the *Phil. Trans.*

Liver of Antimony. A compound of the oxide and sulphide of antimony. The *hepar antimonii* of old pharmaceutical chemistry.

Liver Ore of Mercury. *Hepatic ore.* A bituminous Cinnabar, or sulphide of mercury, from Idria in Carniola.

Liver of Sulphur. Fused tersulphuret of potassium: so called from its *liver colour*.

Livery (Fr. *livrée*). A word derived, probably, from the clothes *delivered* by masters to their servants, in which sense it still continues to be used. At tournaments the cavaliers used to distinguish themselves by wearing the livery or badge of their mistresses; and persons of distinction formerly gave liveries to persons unconnected with their own household or family, to engage them in their quarrels for the time being. The *liverymen* of London are a number of men belonging to the freemen of the ninety-one companies, which embrace the different trades of the metropolis; and are so called because they are entitled to wear the livery of their respective companies. By this body are elected the common councilmen, sheriffs, aldermen, and some other superior officers of the city; and, down to the passing of the Reform Bill in 1832, they had the exclusive privilege of voting at the election of members of parliament.

Livery of Seisin. In Law, a delivery of possession in lands, tenements, and hereditaments, to one that has a right to the same: a ceremony at common law used in the conveyance of lands, whereby an estate of freehold passes by feoffment. [**FEOFFMENT**.]

Living Force or Vis Viva (Lat.). In Mechanics, the product of the mass of a particle into the square of its velocity. [**FORCE**.]

Livre (Fr.; Lat. *libra*, a pound). An ancient French coin, which appears as early as 810 A.D. It was at first divided into twenty *solidi*, and afterwards into twenty *sous*. At the French revolution the *franc* was substituted for the *livre*.

Lixivium (Lat. *lye*). A term employed by the old chemists to signify an alkaline ley or solution.

Lizard. [LACERTA.]

Llandeilo Flags. A group of hard dark-coloured sandy or gritty beds readily splitting into flag-stones. This group is of considerable local importance, and belongs to the Silurian series developed in South Wales. The flags lie near the top of the lower division of the Silurian rocks, as recognised by Sir R. Murchison, passing into the lower subdivision of the Caradoc sandstone, part of which is Upper Silurian. The Llandeilo flags are rich in fossils, *graptolites* being especially abundant in them. They also contain valuable metalliferous veins in Shropshire. They are represented in France by the slates of Angers, and in America by the Utica slates. It is chiefly in Wales that they exhibit that fissile character which has given them the name of flags. They afford many stones useful for paving and other economic purposes.

Llanos (Lat. *planus*, *level*). Tropical plains, continuations northward of the forest plains of the Amazons. [SILVAS.] Their area is about 350,000 square miles, and the whole are destitute of trees. They consist of low table-lands, nearly barren for the most part, sloping at first, and then ranging at a dead level between the Amazons and the Caribbean Sea. These are called the *Llanos altos*. The larger plains are lower, but also nearly barren, the soil being sand over calcareous rock without rocks or pebbles. Although without cultivation, grasses and a few bushes cover parts of these plains.

Lloyd's List. A well-known periodical publication, which contains a full account of shipping intelligence. It derives its name from Lloyd's coffee-house, so long celebrated as the resort of all classes connected either with the mercantile or shipping interest; and its importance in supplying full, trustworthy, and early maritime information cannot be easily overrated. It has been in existence since 1716.

Loach. [COBITIS.]

Load-line. In designing a ship, the load-line is the supposed line of deepest immersion when she is fully laden. Vessels are usually so built that the immersion shall be deeper aft than forward.

Loadstone. [LODESTONE.]

Loam (A.-Sax. *lam*, Ger. *leim*, *clay*). A variety of clay in which there is sufficient sand and limestone to render it loose in texture and well adapted to such crops as require a soil in which they can readily expand and assume their natural dimensions. The quantity of silica which clays are capable of holding mixed up with them without losing their peculiar characteristics is very large, amounting in some cases to nearly ninety per cent. of the whole soil.

Loamy Soil. In the language of practical agriculturists and gardeners, is one in which clay exists: it is called *heavy* or *light*, as the clay may be more or less abundant; and sandy, gravelly, or calcareous, as these earths predominate respectively in the composition. In

general, loamy soils are more fertile than sand or chalk; but the fertility of any soil is always to a certain extent relative to the nature of the subsoil, and to the local climate.

Loan. In Finance, a term employed to designate such advances for the purposes of national administration as are demanded by temporary exigencies. In the middle ages, when public credit was low, and the method of joint action familiar to modern capitalists, for the purpose of contributing to the necessities of government by voluntary subscription, was unknown, violent means were resorted to in order to meet any emergency; though in general the compulsory contribution was coupled with a delusive promise of repayment. Borrowing was a frequent expedient of government before the Revolution; but no effectual guarantee for the liquidation of the principal sum borrowed, or for the punctual payment of interest on advances, was given till after the settlement of 1688. Since this time, however, it has been found essential to the security of government, that trustworthy pledges for the guarantee of public debts should be afforded to lenders; and one by one European and other civilised communities have entered into obligations intended to secure public credit, and have been constrained more or less exactly to keep such obligations.

In general, loans are negotiated by individuals or banking houses, who contract to supply the borrowing government with the sum required, either in a variable quantity of money, but a fixed quantity of stock, or in a fixed sum of money at a varying rate of interest. The former is the method which has generally been adopted in this country; the finance minister advertising for tenders of so many millions of stock, and trusting that the competition of capitalists will raise the percentage paid for the stock to the highest rate which the money market will permit. Hence a large portion of the national debt of the United Kingdom is in effect factitious, the nation not having received much more than three-fifths of the sum which is taken as the existing indebtedness of the community to its public creditor. The question, indeed, whether this method of borrowing is ultimately advantageous or the contrary, is still matter of debate; it being urged, on the one side, that the extinction of debt is rendered more difficult by the creation of so large an amount of factitious obligations; and on the other, that the terms on which the loan is procured are always more favourable when the rate of interest is invariable, and the stock therefore uniformly negotiable.

In most other countries, loans have been effected at variable rates of interest. Such a method has this advantage, that when public credit is high, and capital abundant, it is possible to lower the rate of interest on loans already effected, by offering the public creditor the choice of repayment, or as an alternative a diminished percentage on his capital. Large amounts of stock in this country have, at

LOASACEÆ

different periods, been virtually extinguished by the possibility which has sometimes occurred of offering lower terms to the public creditor in consequence of the price of the stock having risen above par. In short, the government has been enabled to do that which a mortgagor does who, taking advantage of a low rate of interest, extinguishes one mortgage, and creates another on more favourable terms.

The government of this country has from time to time negotiated loans on the latter method. Its first loans were all of such a nature, the other system having been adopted after the consolidation of the various three per cent. stocks in 1752. Still, though the greater part of the sum borrowed was funded in perpetual annuities at three per cent. (called, by an abbreviation of the term used in the Act of 1752, *consols*), other portions were created in other stocks. For instance, in a loan negotiated in 1794, the lender of 100*l.*, in addition to 100*l.* stock in consolidated annuities, received 25*l.* four per cents. and an annuity of 11*s.* 6*d.* for 66½ years. The 'loyalty loan' of 1797 was negotiated in a five per cent. stock. It rarely happens, of course, that the lender can, in case of bad faith on the part of governments, use any means in order to compel payment; but the police of the Stock Exchange exercises a powerful control over a dishonest administration, by excluding, in the case of fraud or repudiation, all the transactions of the offending government from the open money market. [NATIONAL DEBT.]

Loasaceæ (Loasa, one of the genera). A natural order of epigynous Exogens belonging to the Cactal alliance, found chiefly in the temperate regions of America, and distinguished by their distinct petals and sepals, their scattered stamens, their confluent pendulous ovules, and albuminous seeds. The principal genus, *Loasa*, consists of stinging herbs.

Lobate (Gr. λοβός, *a lobe*). A term applied by Linnæus to the feet of those birds, as the grebe, which were furnished at their sides with broad-lobed membranes.

Lobby. In a ship, a small cabin adjoining the bread-room, and appropriated to the use of the surgeon.

Lobeliaceæ (Lobelia, one of the genera). A natural order of epigynous Exogens of the Campanal alliance, especially distinguished by its valvate irregular corolla, its syngenesious anthers, its stigma being surrounded by hairs, and its two or more celled ovary. They are mostly herbs or subshrubs, abounding in various parts of the world, in tropical or subtropical climates, and include the important genus *Lobelia*, many species of which have acrid properties, and are also used in medicine. One of them, *L. inflata*, a North American species, called Indian Tobacco, is a powerful narcotic poison. Its leaves have been used in medicine as an expectorant and emetic. They are said to quiet the action of the heart and relax the muscles, and to be of great use in allaying the paroxysms of spasmodic asthma, and as a relaxant in whooping-cough.

LOCK

Lobeline. A peculiar acrid oil, contained, along with *Lobelic acid*, in the leaves of the *Lobelia inflata*.

Lobolite. A magnesian variety of Idocrase from Gökum in Finland.

Lobster. A well-known Crustacean, the *Palinurus vulgaris* of Cuvier. Several species are used as food on the Continent, but the Norway Lobster is the only important one brought to the British market. The peculiar colouring matter of the shell changes from black to red when immersed in boiling water.

Local Problem. In Geometry, a problem in which the number of given conditions being insufficient to determine the position of a point, but still sufficient to prevent this position from being perfectly arbitrary, the curve or surface is required upon which the point must be situated. Thus, 'to find all points equidistant from two given fixed points,' is a local problem. The right line which bisects, and is perpendicular to the line joining the given points, contains all the points required, and constitutes the solution of the problem. [D-TERMINATE PROBLEM.]

Locative Case. In Grammar, the case expressive of locality. Such a case existed originally in all the Aryan languages; but in the later dialectical formations it has been confused with other cases owing to the similarity of the suffix by means of which it was constructed. This suffix in Sanscrit, which retained the case in all numbers, is *i*; and it was manifestly the same in Greek and Latin. Thus, when our ordinary grammars tell us that in the phrase, 'Romæ vixit,' *he lived at Rome*, Romæ is in the genitive case, they fall into the great error of confusing the genitive case with the locative Roma-i = Romæ. Hence arises that most confusing and mischievous of grammatical rules, which tells the learner that position at a place is in Latin to be expressed by the genitive singular of the first and second declensions of nouns, but by the dative or ablative case of the singular number with nouns of the third declension, or of the plural number of the first. Instead of this rule, which has neither rhyme nor reason to recommend it, all that is to be said is that these so-called genitives and ablatives are really the old locative case, as may be seen by comparing Roma-i = Romæ, Abyd-i, Carthagin-e, Athen-is, with Σαργη, Σαλαμιν-ι, Ἀθην-αις, &c. It was only in later Latin that the locative assumed the same form with the genitive, the original termination of the latter in the first declension being in -as, as shown by the form 'pater-familias'; and, indeed, the idea of any genitive at all is seemingly of later growth, everything that is abstract in language having been originally concrete. (Max Müller, *Lectures on Language*, first series, vi.)

Loch. The Scotch term for LAKE [which see]. [LOUGH.]

Lochaber Axe. [BATTLE-AXE.]

Lock (A.-Sax. loc). An instrument composed of springs and bolts, used for the fasten-

LOCK

ing of doors, drawers, chests, &c. A good lock is a masterpiece of smith's work, and requires much delicacy and art in contriving and varying the wards, bolts, springs, and other parts of which it is composed, so as to adjust them to the places where they are serviceable, and to the various occasions of their use. The structure of locks is so varied, and the number of inventions of different sorts so extended, that we cannot attempt to enumerate them. Those placed upon outer doors are called *stock-locks*; those on chamber doors are called *spring-locks*; such as are hidden in the thickness of the doors to which they are applied, are called *mortice-locks*; and those that are applied upon the outside of the doors are called *iron rimlocks*. The padlock is too well known to require description. We here add the conditions which, according to Mr. Nicholson, appear necessary in a lock of the most perfect kind: 1. That certain parts of the lock should be variable in position through a great number of combinations, one only of which should allow the lock to be opened or shut; 2. That this last-mentioned combination should be variable at the pleasure of the possessor; 3. That it should not be possible, after the lock is closed and the combination disturbed, for anyone, not even the maker of the lock, to discover by any examination what may be the proper situation of the parts required to open the lock; 4. That trials of this kind should not be capable of injuring the lock; 5. That it should absolutely require no key, and be as easily opened in the dark as in the light; 6. That the opening and shutting be done as easily, and by a process as simple, as a common lock, either with or without a key, as may be desired; 7. That the keyhole be defended, concealed, or inaccessible; 8. That the key may be used by a stranger without his knowing, or being able to discover, the adopted combination; 9. That the key be capable of adjustment to all the variations of the lock, and yet be simple; 10. That the lock should not be liable to be taken off and examined, whether the receptacle be open or shut, except by one who knows the adopted combination. These considerations involve a mechanical problem of great difficulty; but much towards its accomplishment has been effected in various inventions by Bramah, Chubb, Taylor, Hobbs, &c. The Romans seem to have known the use of tumblers in their locks, if we may judge from the specimens from Pompeii.

LOCK. That part of a musket or fowling-piece which has to do with the ignition of the charge by percussion.

LOCK. In internal Navigation, the part of a canal included between two floodgates, by means of which a vessel is transferred from a higher to a lower level, or from a lower to a higher. It is also applied to the contrivance by which vessels are maintained at the level of high tides in harbours exposed to variations of level. [CANAL.]

On Shipboard, compartments of

LOCOMOTIVE ENGINE

the hold for the stowage of chain cables and solid shot. They are centred round the foot of the mainmast; that position for these weighty objects being found to give the easiest motion to the ship as she pitches in a head sea.

Lockjaw. [TETANUS.]

Locomotion (Lat. *locus*, a place, and *motio*, a moving). Such motion as is attended by change of place in the body which moves, in contradistinction to motions which a body may have which is stationary. Thus a clock, a mill, a lathe moves; but as no change of place of the machine is produced, such motion is not locomotion. A steam engine which being fixed in its position impels other bodies, is a stationary engine; but one which travels with the bodies which it drives is called a locomotive engine.

Locomotive Engine. Any engine which, being employed to draw loads in transport overland, travels with the load which it draws.

Since the improvement and extension of iron railways, this term has been exclusively applied to the steam engines by which loads are drawn upon them. Although, strictly speaking, the steam engine by which a ship is propelled is a locomotive engine, it is not usual to apply that term to it; such an engine being called a *marine engine*. [STEAM ENGINE.] The term locomotive engine must, therefore, as at present used, be understood to express the travelling steam engine by which trains are drawn on railways.

History of the Locomotive Engine.—The first practical application of the steam engine as a locomotive power took place in 1804, on a railroad at Merthyr Tydvil, in South Wales. The engine was constructed by Messrs. Trevithick and Vivian, under a patent obtained by them two years previously. This engine, in several respects, resembled in its form and structure those which have been since used for a like purpose.

The early projectors of locomotive engines were all impressed with a notion that the adhesion of the driving wheels to the rails must be insufficient to enable the power applied to these wheels to give progressive motion to the carriage; and, without thinking it necessary to ascertain by actual experiment whether such were really the case or not, they expended much ingenuity and capital in devising means for overcoming this difficulty, which, after all, turned out to be merely imaginary. Engineers were, in fact, impressed with a notion that if any power compelled the wheels to revolve, they would merely slip upon the rails, and that the carriage or engine would remain stationary. To provide against this, Messrs. Trevithick and Vivian proposed to make the external rims of the wheels intended for common roads rough and uneven, by surrounding them with projecting heads of nails or bolts, or by cutting transverse grooves in them. Seven years afterwards Mr. Blenkinsop, of Leeds, obtained a patent for a method of surmounting this imaginary difficulty by the substitution of a rack rail for the ordinary smooth rail, and constructing teeth on the driving wheels to work in the teeth of this rack. Various other ingenious contrivances

LOCOMOTIVE ENGINE

were subsequently produced for the same purpose until about the year 1814, when experience at length forced upon engineers the knowledge of the fact, that the adhesion of the tires of the wheels with the rails was amply sufficient to propel the engine, even when drawing a great load after it.

The next stimulus which the progress of this invention received arose from the project of constructing a railway between Liverpool and Manchester, for the purposes of a general traffic. When this project was undertaken, it was not decided what moving power was most eligible—whether horse power, stationary steam engines, or locomotive engines; but the first, for many obvious reasons, was soon rejected, in favour of one or other of the last two, and after an elaborate enquiry the decision of the directors was given in favour of locomotive power. Prizes were therefore proposed to be given, under certain stipulations, to those who would construct the most effective locomotive engines for the purposes of the road.

This proposal produced, as was anticipated, much competition; and the spirit of emulation being roused, a trial was appointed, which took place on the railway in October 1829. Engines of several forms were produced; and the prize was awarded to one, called the *Rocket*, constructed by Mr. Robert Stephenson, the son of Mr. George Stephenson, the engineer of the railway. (Jeaffreson and Pole, *Life of Robert Stephenson*.) In the first trial, this engine attained the then astonishing speed of twenty-nine miles an hour; and when, unhappily, at the ceremony of the opening of the railway, the accident occurred which deprived the country of Mr. Huskisson, his wounded body was conveyed, by the same engine, a distance of about fifteen miles in twenty-five minutes, being at the rate of thirty-six miles an hour. This engine, which involved in its construction all those mechanical arrangements to which the extra-

Fig. 1.

ordinary speed and power of the locomotive engine of the present day are due, is represented in elevation in fig. 1; and a cross section of the boiler and furnace is represented in fig. 2. It is supported on four wheels, the weight being principally thrown on the larger pair worked by the engine. The boiler is a cylinder 6 feet long, having the chimney at

one end, and the fire box B at the other. This box is surrounded with a hollow casing, which communicates with the bottom of the boiler by a tube C, and with the top by a tube D. The water in the boiler, therefore, flows into the casing, and fills it to the same level as that which it has in the boiler. When the engine is at work, the boiler is kept about half filled with water, and, consequently, the casing round the furnace is completely filled. Steam is abundantly generated in this casing, exposed as it is on every side to the radiant heat of the fire; this steam rises in bubbles, and passes through the tube D into the boiler. The lower part of the boiler is traversed by a number of copper tubes, the ends of which appear in fig. 2. The flame and heated air proceeding from the burning fuel pass through these tubes, and, after traversing the whole length of the boiler, escape into the chimney, imparting, on their passage, heat to the water in the boiler. The necessary draught through the furnace is maintained by causing the cylinders to discharge the waste steam into a pipe, which is presented up the chimney, and is called the blast pipe. There are two cylinders placed outside the engine, on either side of it, as represented in fig. 1; these are placed in a diagonal position, and their rods move in guides; the end of the piston rod is connected with one of the spokes of the wheels, by a connecting rod, and the piston, as it is driven by the steam in each direction in the cylinder, causes the wheels to revolve.

Fig. 2.

The circumstances in this mechanical arrangement, on which the rapid production of steam depends, are twofold; first, the extensive surface exposed to the radiant heat of the fire, by the casing surrounding the fire box, and by the tubes, twenty-five in number and only three inches in diameter, by which the flame and heated air are conducted through the boiler from the fire box to the chimney; and secondly, by the powerful draught maintained in the furnace by the current of steam constantly discharged up the chimney. It has been mainly by bringing these principles more fully into operation, that all the improvements since made in the locomotive engine have been effected.

Having thus briefly sketched the history of the locomotive engine, we will now give a description of such a machine in one of its most common forms.

Description of the Locomotive Engine.—A longitudinal vertical section of a locomotive engine is represented in fig. 3; and a plan of the working machinery, including the cylinders, pistons, eccentrics, &c., which are under the boiler, and by the operation of which the engine is driven, is represented in fig. 4.

The boiler, as has been explained in the engines already described, is a cylinder placed upon its side; the fire box consists of two

LOCOMOTIVE ENGINE

casings of metal, one within the other, bolted together by stays, represented at *k*; the fire grate is represented at *D*. The fire door is

Fig. 3.

represented at *g*, opening upon the platform where the engineer stands. It will be perceived in the section fig. 3, as well as in the

Fig. 4.

plan fig. 4, that the fire box is on every side surrounded by the water contained between the two casings, the level of the water in the boiler being above the roof of the fire box. The tubes by which the flame, and the products of combustion, are drawn from the fire box into the smoke box, are represented at *E*, fig. 3. The smoke box containing the cylinders and blast pipe, is represented at *F*. In the engine from which this drawing was taken, the boiler is a cylinder 7½ feet long and 3½ feet diameter: it is clothed with a casing of wood, represented at *a*, and bound round by iron hoops screwed together at the bottom. Wood being a slow conductor of heat this covering has the effect of keeping the boiler warm and checking the condensation of steam.

The external casing of the fire box, *BB*, is nearly square in its plan, as seen in fig. 4, being 4 feet wide, and 3 feet 7½ inches long; it is constructed of wrought-iron plates, and descends two feet below the boiler, as seen in fig. 3; the top being semi-cylindrical, of a diameter greater than that of the boiler, and concentric with it. The inner casing, *k k*, fig. 4, is similar in shape to the external; but it is lower, and flat at the roof, as seen in fig. 3. The space between the two casings is from 3 to 4 inches in width. This internal fire box is made of copper plates.

As the top of the fire box would be liable to be destroyed by the action of the fire if the level of the water in the boiler were suffered to fall below it, so as to leave it uncovered, a leaden plug *m* is inserted in it, which would melt out before the copper would become injuriously heated, and the steam rushing out at the aperture would cause the fire to be extinguished. The tubes *E*, which serve to conduct

the flame through the boiler to the smoke box, are made of the best rolled brass, ⅛th of an inch thick, and 1½ of an inch in external diameter; they are 124 in number, and the distance between tube and tube is ¾ of an inch. The tubes act as stays, connecting the ends of the boiler to strengthen them; but besides these there are rods of wrought iron, represented at *o*, fig. 3, which extend from end to end of the boiler, above the roof of the fire box. The smoke box *F*, containing the cylinders, steam pipe, and blast pipe, is 4 feet wide, and 2 feet long; it is formed of wrought-iron plates, riveted in the same manner as those of the fire box. From the top of the smoke box, which, like the fire box, is semi-cylindrical, rises the chimney *G*, 15 inches diameter, made of ¾-inch iron plates, riveted and bound round by hoops. Near the bottom of the smoke box the working cylinders are placed side by side, in a horizontal position, with the slide valves upwards, as seen in fig. 4.

At the top of the external fire box, fig. 3, a circular aperture is formed 15 inches in diameter; and upon this aperture is placed the steam dome, *T*, 2 feet in height, and secured to the aperture by nuts. The steam dome is made of brass nearly half an inch thick. A funnel-shaped tube *d*, with its wide end upwards, is flanged upon the side of the great steam pipe *S*, and is carried upwards so that its mouth is near the top of the steam dome *T*. In order to pass into the steam pipe *S*, the steam which fills the upper part of the boiler *A* must ascend into the steam dome and enter the funnel *d*, as indicated by the bent arrow in fig. 3. This arrangement prevents, in a great degree, the effect of *priming*, by which word is expressed technically the spray of water which rises from the water of the boiler, and is mixed with steam in the upper part of it: as the steam ascends into the steam dome this spray falls back, and nothing but pure steam enters the funnel *d*. The wider part of the great steam pipe *S* is flanged, and screwed at the hinder end to a corresponding aperture in the back of the fire box, where the engineer stands; this opening is covered by a circular plate, secured by screws, having a stuffing box in its centre, of the kind used for the piston rods of steam cylinders. Through this stuffing box the spindle or rod *a'* of the regulator passes; and to its end is attached a winch *h*, by which the spindle *a'* is capable of being turned. To the other end of this spindle at *e* is attached a plate, which moves upon apertures formed in the cover of the end of the great steam pipe *S*; so that, by turning the winch *h* more or less, this plate *e* may be removed more or less from over the openings; and thus the steam may be allowed to enter the steam pipe *S* from the steam dome *T* in greater or less quantity, or may be shut off altogether. The steam pipe *S* being enclosed within the boiler, is maintained at the same temperature as the steam in the boiler; and therefore the steam, in passing through it, is

LOCOMOTIVE ENGINE

not liable to condensation. The steam pipe, passing through the tube plate at the front of the boiler, is turned down at right angles in the smoke box, where it is divided into two branches, one being conducted to each of the valve boxes of the cylinders. The lower ends of these branches are flanged to the valve boxes at the ends of the cylinders nearest to the boiler: by these pipes the steam is conducted into the valve boxes, or steam chests, from which it is admitted by slide valves to the cylinders to work the pistons. On the upper sides of the cylinders are the valve chests U, communicating with the passage *m*, fig. 4, leading to the back of the cylinder, *n* leading to the front, and *o* leading through the side pipe P' to the blast pipe. These openings are governed by a slide, so that, when steam is admitted through *m*, the communication shall be opened between *n* and *o*. Thus, when steam is admitted to the back of the cylinder, the steam from the front will flow from *n*, through *o*, into the blast pipe. When the piston reaches the front of the cylinder, then the slide opens a communication between *n* and the steam pipe, and between *m* and *o*. Thus steam will be admitted to the front of the cylinder, while the steam from the back will escape from *m*, through *o*, to the blast pipe. In this way, by the alternate shifting of the slide, steam is admitted alternately to each end of the cylinder, and allowed to escape from the other end, and the alternate motion of the piston in the cylinder is thereby maintained. The pistons used in locomotive engines are of the kind called *metallic pistons*, and, from their horizontal position, they have a tendency to wear unequally in the cylinders, their weight pressing them on one side only; but, from their small size, this effect is found to be imperceptible in practice. The cross pipe P', which communicates with the eduction passage *o*, in each of the valve boxes, has an opening in the centre presented upwards, as seen in fig. 4. To this opening is flanged the base of the blast pipe P, fig. 3, which rises in a direction slightly curved, and has its mouth presented upwards in the centre of the chimney G. The steam which is discharged at each stroke of the pistons from the cylinders passes through this pipe, and up the chimney by puffs. When an engine is moving slowly, these puffs are distinctly audible, resembling the coughing of a horse; but when at full speed, they succeed each other so rapidly that the ear can scarcely distinguish their intervals. This stream of waste steam, continually rushing up the chimney, maintains the necessary draught in the fireplace; the upper current thus produced in the funnel is a corresponding current into the smoke box F, through the tubes E; and there is this excellence in the arrangement, that the force of the draught in the chimney, being proportional to the quantity of steam produced, must be therefore proportional to the quantity of fuel necessary to be consumed.

The force of the steam thus impressed upon

the pistons is communicated by the piston rods Y, fig. 3, the cross heads of which move in guides, to the connecting rods B, which are attached to the crank pins of the working axle C; so that, as the piston rods are driven backwards and forwards in the cylinders, the working axle is made to revolve. This axle has the driving wheels of the locomotive fixed upon it, and the engine is impelled forward upon the railway as the wheels revolve.

The method by which the slides are made to govern the admission and escape of the steam to and from the cylinders is nearly the same as in the steam engine used for the general purposes of manufacture; and for a general description of the method, see STEAM ENGINE. Meanwhile, it may be here briefly stated, that this is effected by two circular plates called *eccentrics*, fixed at E E, fig. 4, on the great working axle. These eccentrics are circular plates or rings, formed upon or attached to the axle so as to revolve in their own plane, forming, in effect, a part of the axle itself; but they are so placed that their centres do not coincide with the centre of the axle, and consequently, as they revolve with the axle, their centres are alternately thrown backwards and forwards, as they pass on the one side or the other of the axle. These circular plates are surrounded by rings, within which they revolve, but which do not revolve with them. These rings are alternately thrown backwards and forwards, by the play of the eccentrics; and to these rings are attached rods *e e*, which communicate motion to the arms which drive the rods of the slides. Thus the alternate motions of the eccentrics backwards and forwards proceed from the working axle, produce a corresponding backward and forward motion in the slides, and thereby govern the admission and escape of the steam to and from the cylinders. When it is required to reverse the motion of the engine, i.e. to make it move backwards, the motion of the slides, and therefore the positions of the eccentrics on the working axle, must be the contrary of that necessary to produce a progressive motion. Sometimes this is effected by shifting the position of the eccentrics on the working axle; but more commonly it is effected by a second pair of eccentrics, represented at F F, fig. 4, placed on the axle in a position contrary to the others. When the engine is driven backwards the eccentrics E E are thrown out of gear, and the eccentrics F F are brought into action.

As all the moving parts of the engine require to be constantly lubricated with oil, to diminish the friction and keep them cool, oil cups for this purpose are fixed upon them. In some engines these oil cups are attached separately to all the moving parts: in others they are placed near each other in a row on the side of the boiler, and communicate by small tubes with the several parts to be lubricated.

The tender is a carriage attached behind the engine, and close to it, carrying coke for the supply of the furnace, and a tank containing water for the boiler. The feed for the boiler

LOCOMOTIVE ENGINE

is conducted through a curved pipe proceeding from the tank, and carried first downwards, and afterwards in a horizontal direction, as represented at K, fig. 3, under the boiler. It communicates with a forcing pump, which is worked by an arm driven by the cross head of the steam piston. By this pump water is constantly forced into the boiler, so long as the pump is kept in communication with the tank; and this communication may be opened or cut off by a cock *l*, governed by the engineer. As the feed of the boiler by the introduction of cold water checks the activity of the evaporation, it is the custom not to feed the boiler regularly and constantly, but to throw on the feed when the work on the engine is light and the consumption of steam small, and to shut it off when much steam is required. The circumstances of a railway naturally suggest this. When the engine is ascending an incline all the steam which the boiler is capable of producing is required, and therefore the activity of the boiler is stimulated by shutting off the feed; but in descending an incline less power is required, and the feed is put on.

Express Locomotive Engines.—The exigent demand for speed arising out of the competition of the rival gauges and the establishment of express trains, has caused engines of a much more powerful class to be introduced since the first edition of this work was published. Annexed we give examples of this class of engine, being the express engine designed by Mr. Gooch for the Great Western Railway (fig. 5), and Crampton's express engine (fig. 6) applicable to the narrow gauge. These engines were both displayed at the Great Exhibition

Fig. 5.

of 1851. The cylinders of Gooch's engine are each 18 inches in diameter and 24 inches stroke; the driving-wheels are 8 feet in dia-

Fig. 6.

meter; the fire-grate contains 21 square feet of area; the heating surface of the fire box is 153 square feet. There are in all 305 tubes of 2

LOCUS

inches diameter, giving a surface in the tubes of 1,799 square feet: the total heating surface, therefore, is 1,952 square feet. Mr. Gooch states that an engine of this class will evaporate from 300 to 360 cubic feet of water in the hour, and will convey a load of 236 tons at a speed of 40 miles an hour, or a load of 181 tons at a speed of 60 miles an hour. The weight of this engine empty is 31 tons; of the tender $8\frac{1}{2}$ tons; and the total weight of the engine when loaded is 50 tons.

Traction on Roads and Railways.—The tractive force requisite for drawing carriages over well-formed and level common roads is about 1-36th of the load at low speeds. The tractive force requisite for drawing carriages upon railways is about 1-300th of the load, or about $7\frac{1}{2}$ lbs. per ton at low speeds; but in the case of very well formed railways the force necessary for traction is less than this. The resistance, however, increases very rapidly with the speed of the train; and Mr. Gooch has ascertained experimentally that it requires a power of 1,018 horses to be developed in the cylinders to give to a train weighing 149 $\frac{1}{2}$ tons a speed of 61 $\frac{1}{2}$ miles an hour. Of this power 796 horses are expended in propelling the train, and the residue is expended in overcoming the resistance of the blast-pipe, or, in other words, in blowing the fire. The evaporative power of a locomotive boiler varies as the fourth root of the speed.

Locomotive Power. This term denotes, in contradistinction to stationary power, any kind of moving power applied to the transport of loads on land, and travelling with the load which it draws. Horses employed to draw carriages or carry loads are locomotive powers. [LOCOMOTIVE ENGINE.]

Loculicidal (a word coined from the Lat. *loculus*, a cell, and *cicio*, to move). In Botany, that mode of dehiscence which consists in the ripened carpels splitting through their backs.

Loculus (Lat.). In Botany, a cell or cavity. The term is usually applied to the cells of the ovary.

Locum Tenens (Lat. *holding a place*). A term denoting a deputy or substitute; the French form of the phrase is *LIEUTENANT* [which see].

Locus (Lat. *place*). In Ancient Geometry, a line, right or curved, every point of which satisfies given conditions. [LOCAL PROBLEM.] Thus the locus of a point equidistant from two given fixed points A and B is the right line which bisects AB perpendicularly.

When the locus of the variable point was a straight line or a circle, it was called by the ancient geometers a *plane locus*; and when it was one of the conic sections, a *solid locus*.

Plane loci formed a branch of the ancient analysis which, according to the account of Pappus, was treated of by Apollonius in two books which have been lost. They were partly restored by Schooten, a Dutch geometer, who flourished in the seventeenth century, and by Fermat; but afterwards in a complete manner by Dr. Simson of Glasgow, whose

treatise *De Locis Planis*, published in 1749, is a model of geometrical elegance. The principal propositions may be found in Leslie's *Geometrical Analysis*.

In Modern Geometry, the term *locus* is used more generally, to indicate, not only the curve described by a variable point, but also the surface generated by a variable curve. Thus the locus of a right line which rests upon three fixed right lines, not in the same plane, is a hyperboloid of one sheet. Envelopes, again, may be regarded as the loci of their CHARACTERISTICS [which see].

The *locus* of an equation, in algebraic geometry, is the curve or surface upon which are situated all the points whose coordinates satisfy that equation. In this manner, loci are distinguished into *orders*; the order of a locus being simply the degree of the corresponding equation.

Locust (Lat. *locusta*). The common name of a species of insects, forming a group or sub-genus of the *Gryllus* of Linnaeus. They have coloured elytra, and large wings, disposed when at rest in straight fan-like folds, as in other *Orthoptera*, and frequently exhibiting bright blue, green, or red colours. The thorax is capacious, to afford room for the powerful muscles of the wings, and is marked in many species with one or more crests or wart-like prominences. The locusts fly by starts, but frequently rise to a considerable height. Certain species, called *migratory locusts*, unite in incalculable numbers, and emigrate, resembling in their passage through the air a dense cloud; wherever they alight, all signs of vegetation quickly disappear, and cultivated grounds are left a desert. But the mischief does not end here; for when dead, the mass of decomposing bodies is so great that the air becomes poisoned by the fetid exhalations. The second chapter of Joel gives a powerful description of the devastation committed by these destructive insects.

M. Miot, in his translation of Herodotus, has given it as his opinion, that the heaps of bodies of winged serpents which that historian states that he saw in Egypt, were nothing more than masses of this species of locust. These insects are eaten in various parts of Africa, where the inhabitants collect them both for home consumption and for commerce. They take away their elytra and wings, and preserve them in brine. One species (*Aoridium migratorium*, Latr.) occasionally commits devastations in the south of Europe and Poland; and stragglers have occasionally reached our own coasts. In the United States, the term *locust* is applied to a species of *Cicada*, which by their numbers and voracity are almost as destructive as the true locusts of the Old World.

Locust-tree. The *Ceratonia Siliqua*. The name is also sometimes applied to the *Robinia Pseud-Acacia*.

Locusta (Lat.). In Botany, a term applied to that form of spike which consists of flowers destitute of calyx and corolla, the place of which is occupied by bracts, and has a flexuose rachis that does not fall with the

flowers. The grasses afford examples. Each part of the inflorescence so arranged is called a *locusta*, the structure of which is as follows: at the base are two opposite empty bracts called *glumes*, one of which is attached to the rachis a little above the base of the other; above the glumes are several florets sitting in denticulations of the rachis; each of these consists of one bract called a *pale*, sometimes with the midrib quitting the lamina a little below the apex, and elongated into a bristle; and of another bract facing the first, with its back to the rachis, bifid at the apex, with no dorsal vein, but with its edges inflexed, and a rib on each side at the line of inflexion; and, lastly, within these pales are situated two extremely minute fleshy scales (*lodicules*), which are sometimes connate, and stand at the base of the sexual organs.

Lode (A.-Sax. *lædan*, to lead). The technical Mining term for a metalliferous or ore-producing mineral vein. In mining districts ore occurs either in mineral veins or in beds. If in the former, the veins are almost invariably found to have one of two or three principal directions, being either nearly parallel to the axis of elevation of the district, at right angles to that direction, or making an angle of 45° with it. The first series are generally called by miners *right-running veins* or *lodes*; the second are *cross courses*; and the third *contra lodes*, sometimes called *caunters*. Lodes differ almost without limit, in length, width, and depth, and also in the nature of their mineral contents. [MINERAL VEINS.]

Lodesman (A.-Sax. *læd-man*, a leader). A pilot for harbour and river duty.

Lodestar (Icelandic *leidar-stierna*, leading star). A name for the pole star.

Lodestone. The name given to magnetic iron-ore when endowed with magnetic polarity; in which case it constitutes the native magnet or lodestone. [MAGNETITE.]

Lodge. [FREEMASONRY.]

Lodgement (Fr. *logement*). In Fortification, an intrenchment hastily thrown up on a captured breach or outwork, in order to maintain the position against recapture.

Lodicula. In Botany, a term given by Paliat de Beauvois to the two minute colourless fleshy hypogynous scales which are situated beneath the ovary of grasses.

Lodicea. The Coco de Mer or Double Cocoa-nut, *L. Seebellarum*, belongs to this genus of palms, which is found only in the Seychelles, and is there so rare as to have been in danger of extinction through the reprehensible practice of cutting down the trees for the sake of the nuts. These great hard black two-lobed nuts are very singular objects. The trunk is set in a very curious socket-like case.

Loess. A local deposit of fluvial origin, consisting of a finely comminuted sand or powdery loam of yellowish grey colour. This sand is chiefly argillaceous matter, with about fifteen per cent. of carbonate of lime and as much quartzose or micaceous sand. It often contains hard calcareous concretions in parallel

LOG

It is unsolidified, and easily washed away. It contains land shells, and sometimes freshwater species. *Succinea elongata* is characteristic of it. It rarely shows signs of stratification, being perfectly homogeneous. It chiefly occupies the valley of the Rhine, and is newer than any regularly deposited rock in the district. It is sometimes seventy feet thick. Near Bâle it caps hills 1,200 feet above the sea.

Log, Log-line. In Sea language, the log is a piece of wood, in the form of a sector of a circle (usually a quadrant) of five or six inches radius. It is about a quarter of an inch thick; and so balanced, by means of a plate of lead nailed to the circular part, as to swim perpendicularly in the water, with about two-thirds immersed under the surface. The log-line is a small cord, one end of which is fastened to the log, while the other is wound round a reel in the stern part of the ship. The log thus poised keeps, in theory, its place in the water, while the line is unwound from the reel as the ship moves through the water; and the length of line unwound in a given time gives the rate of the ship's sailing. This is calculated by *knots* made on the line at certain distances, while the time is measured by a sand-glass of a certain number of seconds. In order to avoid calculation, the length between the knots is so proportioned to the time of the glass that the number of knots unwound while the glass runs down shows the number of miles the ship is sailing per hour. Thus, suppose the glass to be a half-minute one, it will run down 120 times in an hour. Now, distances by sea are reckoned by nautical miles of 60 to a degree; so that each mile contains about 6,100 feet, the 120th part of which is about 51 feet. If, therefore, the knots (which are pieces of coloured cloth) are fastened to the log-line at distances of 51 feet, the number of knots unwound from the reel in half a minute is the number of miles the ship runs in one hour. If the glass runs down in less than half a minute, the intervals between the knots must be diminished in proportion. The first knot is placed about five fathoms from the log, to allow the latter to get clear of the ship before the reckoning commences; and the part of the line between the lead and the first knot is called the *stray-line*. The action of the log is uncertain, currents and other contingencies affecting it. More complicated logs are often used, which themselves register the rate, direction, &c. The log is heaved hourly in men-of-war, and every two hours in merchant-vessels, the particulars being each time entered in the ship's log-book.

Logan Stones or Reeking Stones. The name given in Cornwall and elsewhere to blocks of stone so exactly balanced on three points of the solid rock below, that a slight effort will move them, although their weight may amount to many tons. These are probably natural, and may have been either dropped by ice that has floated over or moved upon the surface during the glacial period, or so shaped by the effect of weathering.

LOGARITHM

Loganiaceæ (Logania, one of the genera). An important natural order of perigynous Exogens, belonging to the Gentianial alliance; in which it is distinguished by having opposite leaves and intervening stipules. The order is mostly tropical, and includes several genera, the most important of which is *Strychnos*, which contains the Poison Nut, *S. nux vomica*; the Tienté, *S. Tienté*; the Woorali, *S. toxifera*; and the Clearing Nut, *S. potatorum*. The *Spigelia* and *Potatis* are also active plants. *Strychnos pseudoquina* is, however, said to be the best febrifuge in Brazil.

Loganite. A hydrated silicate of alumina, magnesia, and protoxide of iron, occurring in the Laurentian limestones of Canada, and named after Sir W. E. Logan.

Logarithm (Gr. λόγος, a proportion, and ἀριθμός, number). Every number may be regarded as a power of another given invariable number or base. The exponent of that power is said to be the *logarithm of the number to that base*. Thus 10 being the base, the logarithm of 1,000 is 3, and generally if $n = a^x$, x is the logarithm of the number n to the base a , or symbolically $x = \log_a n$. Since $1 = a^0$ and $a = a^1$, we at once conclude that the logarithm of 1 is 0 in every system of logarithms, and that 1 is always the logarithm of the base itself. If x_1, x_2 , be the respective logarithms of any two numbers n_1, n_2 , and a the base of the system, we have by definition

$$n_1 = a^{x_1}, \quad n_2 = a^{x_2},$$

and hence

$$n_1 n_2 = a^{x_1 + x_2}$$

whence

$$x_1 + x_2 = \log_a (n_1 n_2),$$

that is to say (1) the logarithm of the product of two or more numbers is always equal to the sum of their logarithms; similarly, since

$$\frac{n_1}{n_2} = a^{x_1 - x_2},$$

it follows that (2) the logarithm of the quotient is the excess of the logarithm of the dividend over that of the divisor. Lastly, since $n_1 = a^{mx_1}$, whether m be integral or fractional, we conclude that (3) the logarithm of any power of a number is the product of the logarithm of the number and the exponent of the power, and (4) the logarithm of any root of a number is obtained by dividing the logarithm of the number by the index of the root.

By means of a calculated table of logarithms, therefore, the operations of multiplication, division, involution, and evolution, may be replaced by the simpler operations of addition, subtraction, multiplication, and division. Hence the great utility of logarithms in numerical computations. The system of logarithms in general use is that known as *Briggs's system*, which corresponds to the base 10. The advantages of the system will be manifest on observing that the logarithms of any two numbers which differ only in the position of the decimal point, have the same decimal part or *mantissa*, and merely differ in their integral parts or *charac-*

LOGARITHM

teristics, which latter can be easily supplied, so that the tables need only contain the several mantissæ. Thus,

$$\log 7359.4 = \log (10^3 \times 7.3594) = 3 + \log 7.3594.$$

Now 7.3594 being between 1 and 10, its logarithm will be between 0 and 1, and will consequently have the characteristic 0; it is in fact 0.8668424. Log 7359.4, therefore, will have the same mantissa with the characteristic 3, which is obviously the number of places to the left of the units place at which significance begins in the number 7359.4. Again, since

$$-0.0073594 = \frac{7.3594}{1000},$$

$$\log (0.0073594) = 0.8668424 - 3.$$

This result, which is in reality negative, is usually written thus $\bar{3}$; 8668424, the mantissa, for obvious reasons, being preserved positive, and the characteristic alone made negative; the latter, it will be observed, indicates that in the number 0.0073594 significance begins three places to the right of the units place, whence is manifest the very simple rule for supplying the characteristic of the logarithm. [SIGNIFICANT DIGITS.]

When a table of logarithms has been calculated to any base, logarithms to a different base can be obtained from it by mere multiplication by a constant factor. Thus $c = 2.7182818284 \dots$ being the base of the natural or Napierian system of logarithms [EXPONENTIAL SERIES], x the natural, and ξ the common logarithm of one and the same number, we shall have the relation $c^x = 10^\xi$, both these quantities being equal to the number in question. Taking the natural logarithms of these equals, we have

$$x = \xi \log_{10} 10 \text{ or } \xi = \frac{1}{\log_{10} 10} x.$$

This number

$$\frac{1}{\log_{10} 10} = 0.4342944819,$$

by which natural logarithms must be multiplied in order to obtain common logarithms, is called the *modulus* of the latter system.

A convergent infinite series, by means of which natural logarithms, and hence all others, may be calculated, is,

$$\log \left(\frac{1+x}{1-x} \right) = 2 \left\{ x + \frac{x^3}{3} + \frac{x^5}{5} + \&c. \dots \right\};$$

the manner in which it is obtained is explained in all text-books. [EXPONENTIAL SERIES.]

Logarithms were invented by Lord Napier, baron of Merchiston in Scotland; and made known in a work published by him in 1614, under the title *De mirifici Logarithmorum Canonis Constructio*. Henry Briggs, a contemporary of Napier, and professor of geometry in Gresham College, constructed another system, having for its base the number 10, which, corresponding with our system of numeration, is much more convenient for the ordinary purposes of calculation. Briggs calculated the

LOGARITHMIC CURVE

logarithms to 14 places, besides the index, of all numbers between 1 and 20,000, and between 90,000 and 100,000, and published them in his *Arithmetica Logarithmica* in 1624. Arian Vlacq, a native of Holland, computed the logarithms of the numbers from 20,000 to 90,000, and thus completed what had been begun and partly accomplished by Briggs; but he reduced the tables to 10 decimal places. Vlacq's *Arithmetica Logarithmica* was published at Gouda in 1628, and contained the logarithms of all numbers from 1 to 100,000, calculated to 10 decimals; as also the logarithms of the sines, tangents, and secants of every minute of the quadrant. Vlacq afterwards, in 1633, published another most valuable work, his *Trigonometria Artificialis*, containing the logarithmic sines, cosines, tangents, and cotangents for every ten seconds of the quadrant, calculated from the natural sines, &c. of the *Opus Palatinum* of Rheticus. In the same year another work of the same kind, the *Trigonometria Britannica*, was published at Gouda, containing the logarithmic sines and tangents for the 100th part of every degree of the quadrant, together with a table of natural sines, tangents, and secants. These had been computed by Briggs.

Logarithms being of constant use in astronomical and trigonometrical calculations, the tables which have been published are very numerous. The most complete are those of Vlacq, already mentioned, to ten decimals; but they are very scarce, and can with difficulty be procured. There is an edition of them by Vega, 1797, also scarce. Gardener's *Logarithms*, printed in 1742, in 4to., and another edition of them at Avignon in France in 1770, are to seven decimals. Callet's *Logarithms*, in 8vo., like Gardener's, contain the logarithmic sines, &c. for every 10 seconds. Taylor's *Logarithms*, in 4to., and also Bagnay's, have them to every second. Hutton's *Logarithms*, and Babbage's *Logarithms of Numbers*, are well known. The latter was carefully collated, and is very accurate and convenient. Hulse's *Sammlung Mathematischer Tafeln* (second stereotyped edition, Leipzig 1849) is also exceedingly accurate and useful.

The above (excepting Vlacq's and Vega's) are all to seven decimal figures, but for many purposes logarithms to a less number of decimals are sufficiently accurate. For navigation and surveying, tables to six figures are the most convenient, as they give in general the trigonometrical lines correct to single seconds. The best tables of this kind are Farley's *Tables of Six-figure Logarithms* (12mo. 1840). For many auxiliary computations in astronomy, it is sufficient to have the logarithms to five places. The reprint of Lalande's *Five-figure Table* by the Useful Knowledge Society (18mo. 1839) is convenient, and may be relied on for accuracy.

Logarithmic Curve. A curve whose abscissæ are proportional to the logarithms of the corresponding ordinates. It may easily be

constructed from its equation $x = m \log y$ or $y = a^x$, where $m = \frac{1}{\log a}$ is the modulus of the system of logarithms whose base is a . This modulus is precisely the subtangent $y \frac{dx}{dy}$ at

any point of the curve, that is to say the portion of the abscissa axis, of constant length, which is intercepted between the tangent and the ordinate at any point. The curve obviously approaches the abscissa axis asymptotically on the negative side of the origin, and recedes to an infinite distance from it on the positive side; it crosses the ordinate axis at the unit of distance above the origin.

The curve was investigated first by Gregory of St. Vincent, and afterwards by Huygens, Euler, and others. With respect to a controversy which arose as to the proper interpretation of the equation $y = e^x$, see Euler's *Anal. Inf.* vol. ii.; Vincent, in Gergonne's *Annales*, vol. xv.; and Gregory in *Cam. and Dub. Math. Journal*, vol. i.

Logarithmic Spiral. A curve imagined by Descartes, and best defined by its polar equation $r = a^\theta$. It has the property of reproducing itself in various ways; its involute, reciprocal, evolute, inverse, pedal, &c. are all logarithmic spirals, as are also its caustic by reflexion and refraction, the light being incident from the pole. It cuts all its radii vectores at a constant angle whose tangent is the modulus of the system of logarithms, having the base a , i. e. the radius vector, corresponding to the angle $\theta = 1$.

Newton proved that if the force of gravitation had been inversely as the cube of the distance, instead of the square, the planets would have shot off from the sun in logarithmic spirals. (*Principia*, lib. i. prop. ix.)

James Bernoulli's paper on this curve in the *Acta Eruditorum*, 1692, is well worthy of perusal as a fine specimen of mathematical eloquence and enthusiasm.

Logic (Gr. λογική, sc. τέχνη, art, from λόγος, discourse). Logic has been defined to be the science, and also the art, of reasoning. It is a science, because it investigates those principles on which reason proceeds: it has been termed an art, as furnishing rules whereby the formal part of an argument may be constructed. Logic was highly valued, perhaps overvalued, among ancient philosophers. The Stoics, in particular, were celebrated for their application of its principles to their own favourite metaphysical discussions. From the abuse of logical knowledge arose the celebrated fallacies of the Sophists, who, according to the satirical representations of Athenian writers, were hired to furnish their pupils with the means of defending right or wrong positions with equal facility. Zeno of Elea is called the father of logic, or dialectics, according to the ancient appellation of the science; but we are not well acquainted with the discipline which he taught: although it can hardly have consisted, as more recent

writers have represented, of a mere manual of captious fallacies. But it is to the master mind of Aristotle that the science owes, as far as we are able to ascertain, its first exposition, and its systematic development. When, in the middle ages, the Aristotelian logic became the foundation of the scholastic philosophy, attempts were made, especially one by the famous Raymond Lullius, to throw the science into a new form, but without success. In consequence of the various misapplications and perversions which the system had undergone in the hands of later dialecticians, it fell into great disrepute in modern times; and many of our first metaphysical writers, as Locke, for example, have treated it with a contempt not wholly undeserved by the ordinary expositions of the nature and objects of the science.

The following sketch gives the outlines of the science, as set forth in Whately's *Elements of Logic*.

However multifarious the subjects to which reasoning may be applied, and however complicated its details may become, the process by which all reasoning is conducted is one and the same. Whoever seeks to prove that because one thing is thus, therefore another thing is so, whether he be a philosopher pursuing a recondite truth, or a labourer commenting on the events of his daily life, cannot travel out of the bounds of Aristotelian syllogism. In analysing the process in question, we find, in the first place, that every truth, or apparent truth, arrived at by reasoning, technically termed a *conclusion*, is deduced from two other propositions, technically termed *premises*, either both expressed, or one expressed and the other implied. In many instances it is at once evident to the mind of one capable of reasoning that if the two premises be true, the conclusion must follow. Thus, if I wish to prove the mathematical truth that every A is equal to B, I find a third quantity, C, which is equal to both; and my argument then assumes the following shape: 'Whatever is equal to C is equal to B; but every A is equal to C, therefore every A is equal to B.' Here the connection between the conclusion and the premises is at once evident and true; but there are many cases in which there is an apparent connection which is in reality false: in other words, from two premises a conclusion is deduced, which, admitting the truth of those premises, does not in reality follow from them. The following, for example, is an instance of a conclusion incorrectly deduced from its premises, which, nevertheless, might at first sight pass current for reasoning: 'Every rational agent is accountable; brutes are not rational agents, therefore brutes are not accountable.' To explain the reason why the first of these two arguments is sound, and the latter unsound, requires the examination not of truths in mathematics or in natural religion, but simply of the common process of reasoning; and logic affords the means of making such an analytical investigation. The first of these arguments is a correct, the latter a false or apparent, syllo-

gism; and the validity of the first and invalidity of the latter depend upon the necessary or unnecessary connection between the premisses and the conclusion. A single sentence may often be found to contain, elliptically expressed, and compressed into a narrow compass, a whole chain of separate syllogisms; but every single conclusion has been arrived at by this process, and by this only.

The principle of the syllogism is contained in the famous maxim termed in the schools of the middle ages the *dictum de omni et nullo*, viz. that 'whatever is predicated (i.e. affirmed or denied) universally of any class of things, may be predicated, in like manner (i.e. affirmed or denied) of anything comprehended in that class.' Thus, for example, in the instance previously given of a valid argument, if it can be predicated of the whole class of things which are equal to C that they are also equal to B; if I find any thing equal to C, I may predicate of it that it is equal to B also. Hence my second premiss, A is equal to C, serves to bring me, logically, to the required conclusion—that A is equal to B. This, therefore, is the general principle on which that process is conducted which takes place in every syllogism.

In order that reasoning may be contemplated simply as reasoning, without any reference to the essential truth or falsehood of the propositions contained in it, and also with a view of furnishing brief and expressive forms, like those of algebra, instead of words at length, a set of arbitrary symbols are employed in logic, to denote the quantity and quality, as they are termed, of propositions. Every proposition either affirms or denies a fact; every proposition also predicates (i.e. affirms or denies) that a certain attribute belongs either to a whole class, or to some members of a class, of objects: propositions are therefore, in quality, either affirmative or negative; in quantity, universal or particular. Thus the four symbols of propositions in logical manuals are, A, universal affirmative; I, particular affirmative; E, universal negative; O, particular negative. And the form of a syllogism, according to the character of each of its premisses and of the conclusion, is expressed by three of these letters. Thus the syllogism first given, consisting of three universal affirmatives (for it will be found, on examination, that each proposition predicates a certain attribute of all the members of a class), will be designated by A A A; a syllogism termed in logical language *barbara*. [SYLLOGISM.]

It is also found, on further analysis, that a syllogism embraces three separate objects or notions, two of which are compared with the third, and in consequence of that comparison pronounced to agree or disagree with each other. Thus, in the syllogism, 'No dishonest man is a good citizen: Caius is a dishonest man; therefore Caius is not a good citizen; the individual object, *Caius*, and the class of objects, *good citizens*, being compared with a

third class, *dishonest men*, are found, the one to agree, the other to disagree, with that class; and hence it inevitably follows that they disagree with each other—i.e. the conclusion of the syllogism is negative. These three objects, or terms, as they are called in logic, occur in every syllogism. The predicate of the conclusion—i.e. that term which, in the conclusion, is predicated of the other, in this instance *good citizen*—is called the *major term*; the subject of the conclusion—i.e. that term of which the other is predicated (*Caius*)—is the minor term; and the term with which the other two are respectively compared, *dishonest man*, is the middle term.

But every word, or combination of words, is not capable of constituting a term—i.e. something which may be predicated of another thing, or of which another thing may be predicated. In the first place, adverbs, prepositions, nouns in any inflection from the nominative case, &c., can only form parts of a term; in logical phrase, they are syncategorematic: adjectives, also, have always impliedly a nominative subjoined, when employed as terms. Verbs are mixed words, being resolvable into a term employed as a predicate, united to the copula or auxiliary verb (*is* or *is not*). Thus, nouns in the nominative case alone are simple terms or categorematics; these, again, are either the name of an individual or the name of the class: the former (singular terms) may be subjects, but cannot be predicates; the latter may be either. Thus, in the proposition '*Crassus* is rich,' the singular term *Crassus* is the subject of which it is predicated that he is rich—i.e. a rich man.

A common term, being a word equally applicable to a number of individuals, expresses a notion formed by the faculty of abstraction. When, for example, we contemplate several individual oak trees, and abstract from each its separate peculiarities of height, growth, &c., we form the notion of an oak. Contemplating a number of trees of mixed species, and abstracting from each its specific peculiarities of leaf, fruit, &c., we next arrive at the common notion *tree*. These common notions or terms are then the *predicables* which can be affirmed or denied of other objects.

Predicables are divided into several kinds, although the division, perhaps, appertains in strictness rather to metaphysical than to logical science. Every predicable is said, according to this division, to express either the GENUS, SPECIES, DIFFERENCE, PROPERTY, or ACCIDENT, belonging to an individual. [See these heads, and PREDICABLE.] But it is to be remembered that a predicable may be referred to one or other of these several kinds, according to the point of view from which it is contemplated. If I say of Cæsar that he is a *man*, I express his species, considering him in those respects in which he differs from other animals. If I say that he was *brave*, I express a property. If I predicate of him the several circumstances in which he absolutely differed from all other men, I express

that property or that bundle of united properties which forms his *difference*. Every predicable, with a little attention, may be ranged under one or the other of these five classes.

The popular system of logic thus set forth by Dr. Whately has provoked a series of controversies which at the least serve to show how strong a power the Realism of the schoolmen has retained even over those who profess to regard their theory with contempt. The views of Whately on the subjects of Predication and Syllogism assign to names a mysterious virtue which the Realists attributed to abstract realities; and if this be so, it follows of necessity that he could not have clearly seen the nature or the object of the science which he was striving to promote. To lay bare the errors and defects of this system, not from any desire to win an intellectual victory, but with the simple wish to show that logic is a true science of which the cultivation is not mere waste of time, is the object of Mr. John Stuart Mill's *System of Logic Ratiocinative and Inductive*. These errors, in Mr. Mill's judgment, are to be traced to the belief that the principle of the syllogism is contained in the Aristotelian dictum *de omni et nullo*, which makes the theory of predication to consist in referring something to a class, i.e. either placing an individual under a class or placing one class under another class, or, in the case of negatives, excluding them from that class. Taken without qualification, this method implies that mankind in the beginning decided on all possible classes, and left to us simply the task of referring everything to its proper class. In refutation of this theory, Mr. Mill remarks that when we say, 'Snow is white,' we think of snow as a class, but not of white objects as a class, and indeed of no other white object except snow and of the sensation of white which is caused by it. 'When I have judged or assented to the propositions that snow is white and that several other things also are white, I gradually begin to think of white objects as a class. But this is a conception which followed, not preceded, those judgments, and therefore cannot be given as an explanation of them. The doctrine, therefore, is founded on a latent misconception of the nature of classification. When it was found that the diamond was combustible, it was referred to a class (of combustibles) to which till then it had not belonged; it was so placed because the proposition is true; the proposition is not true, because the object is placed in the class.' Hence the Aristotelian dictum turns out to be a signal *ὁσπερὸν ἄλλοτερον*, while it is seen that classification is the result of induction applied to the phenomena of nature and to all cognisable facts; and logic, instead of being confined to mere names and formulae, becomes a science which deals with things as we find them; in other words, with facts. In truth, the dictum *de omni et nullo* ceased to have any real force when the theory of the Realists was rejected. 'So long as what were termed universals were regarded as a peculiar kind of substances, hav-

ing an objective existence distinct from the individual objects classed under them, the dictum *de omni et nullo* conveyed an important meaning.

The assertion that the entire nature and properties of the *substantia secunda* formed part of the properties of each individual substance called by the same name, that the properties of *man*, for example, were properties of *all men*, was a proposition of real significance when *man* did not mean *all men*, but somewhat inherent in men and vastly superior to them in dignity. Now, however, when it is known that a class, a universal, a genus or species, is not an entity per se, but neither more nor less than the individual substances themselves which are placed in the class, and that there is nothing real in the matter except those objects, a common name given to them and common attributes indicated by the name, what do we learn by being told that whatever can be affirmed of a class may be affirmed of every object contained in the class? The class is nothing but the objects contained in it; and the dictum *de omni* merely amounts to the identical proposition, that whatever is true of certain objects is true of each of those objects.' But modern philosophers, who would regard the theory of the Realists with contempt, were still under the spell. 'Once accustomed to consider scientific investigation as essentially consistent in the study of universals, men did not drop this habit of thought when they ceased to regard universals as possessing an independent existence; and even those who went the length of condemning them as mere names could not free themselves from the notion that the investigation of truth consisted, entirely or partly, in some kind of conjuration or juggle with those names.' Logic, then, is not concerned primarily, or necessarily, or chiefly, with universals—the propositions which are so called, being nothing more than general statements jotted down in a note-book for convenience of reference, and having a value only in the measure in which they correctly sum up facts. Hence 'propositions are not assertions respecting our *ideas* of things, but respecting the things themselves,' and 'every proposition which conveys real information asserts a matter of fact, dependent on the laws of nature, and not on artificial classification,' all other propositions being simply verbal, and all syllogisms founded on such propositions being merely verbal also, and about as edifying as the revolutions of a squirrel in its cage. This analysis exhibits, then, as the principle of syllogism, not the unmeaning Aristotelian dictum, 'but a fundamental principle, or rather two principles, strikingly resembling the axioms of mathematics. The first, which is the principle of affirmative syllogisms, is that *things which coexist with the same thing coexist with one another*; the second, the principle of negatives, that *a thing which coexists with another thing with which other a third thing does not coexist, is not coexistent with that third thing*. These axioms manifestly relate to facts, not to conventions; and one or

LOGIC

other of them is the ground of the legitimacy of every argument in which facts and not conventions are the matter treated of.' Unless these statements can be refuted, the superstructure of Whately's system of logic is shattered. Thus, the theory that a common term expresses a notion formed by the faculty of abstraction is at once set aside on the ground that no name can be the result of the process of abstraction, which can but give certain qualities as essential or otherwise to the object to be defined, but which does not imply that any other object of comparison exists. The idea that a syllogism is vicious if there be anything more in the conclusion than was assumed in the premisses, still more completely betrays the misconception which underlies the whole system; for it implies 'that nothing ever was or can be proved by syllogism which was not known or assumed to be known before.' Such a view would further involve the admission that ratiocination is not a process of inference, and that syllogism to which the word *reasoning* has so often been represented to be exclusively appropriate is not really entitled to be called reasoning at all. But logicians who speak thus of the syllogism still insist that it is a process of inference. How, then, is this proved? If we say, 'All men are mortal: this or that living being is a man: therefore he is mortal,' we infer new truth, i.e. a truth not ascertained by actual observation, for the being in question is not yet dead; but how do we infer it? 'Do we in reality conclude it from the proposition, All men are mortal? I answer, No.' The error committed is that of overlooking the distinction between the two parts of the process of philosophising, the inferring part and the registering part, and ascribing to the latter the functions of the former. The mistake is that of referring a person to his own notes as the origin of his knowledge. If a person is asked a question, and is at the moment unable to answer it, he may refresh his memory by turning to a memorandum which he carries about with him. But if he be asked how the fact came to his knowledge, he would scarcely answer, because it was set down in his note-book, unless the book was written, like the Koran, with a quill from the wing of the angel Gabriel. How, then, do we know that all men are mortal? From observation of individual cases. From these all general truths must be drawn, and into these they may be again resolved. When, then, we assert that So-and-so yet living is mortal like other men already dead, we may pass through the generalisation, All men are mortal, as an intermediate stage; but it is not in the latter half of the process, the descent from all men to So-and-so, that the inference resides. The inference is finished when we have asserted that all men are mortal. What remains to be performed afterwards is merely deciphering our own notes.' It follows that Whately's assertion that the syllogism is not a peculiar mode of reasoning, is very far indeed from the truth. Far from invariably

inferring particulars from universals, 'all inference is from particulars to particulars. General propositions are merely registers of such inferences already made, and short formulæ for making more. The major premiss of a syllogism consequently is a formula of this description, and the conclusion is not an inference drawn from the formula, but one drawn according to the formula; the real logical antecedent or premisses being the particular facts on which the general proposition was collected by induction.'

To those who may assert that, if this be so, the syllogistic art is useless for the purpose of reasoning, Mr. Mill, admitting that the reasoning lies in the act of generalisation, not in interpreting the record of that act, replies that, 'the syllogistic form is an indispensable collateral security for the correctness of the generalisation itself.' Hence we reach the conclusion that 'the reasoning process is in all cases resolvable into the following elements. Certain individuals have a given attribute: an individual or individuals resemble the former in certain other attributes: therefore they resemble them also in the given attribute. This type of ratiocination does not claim, like the syllogism, to be conclusive from the mere form of the expression; nor can it possibly be so. Whether, for example, from the attributes in which Socrates resembles those men who have heretofore died, it is allowable to infer that he resembles them also in being mortal, is a question of induction, to be decided by the principles or canons which are the tests of the honest performance of that great mental operation.'

Logic, then, far from being concerned only with words or names, is concerned directly with facts. If it be maintained that truths are known to us not only by inference, but also by consciousness or intuition, Mr. Mill replies that with convictions of the latter class logic has nothing whatever to do. 'No science is required for the purpose of establishing such truths; no rules of art can render the knowledge of them more certain than it is in itself. There is no logic for this portion of our knowledge.' Logic, then, 'is not the science of belief, but the science of proof or evidence. In so far as belief professes to be founded on proof, the office of logic is to supply a test for ascertaining whether or not the belief is well grounded.' We are thus brought to a question of paramount importance. 'As all inference, consequently all proof, and all discovery of truths not self-evident, consists of inductions and the interpretation of inductions, as all our knowledge, not intuitive, comes to us exclusively from that source, the main question of the science of logic is the enquiry, What is induction? Although the proposition that the course of nature is uniform, is the fundamental principle of induction, it would yet be a great error to offer this large generalisation as any explanation of the inductive process. On the contrary, it is in itself an instance of induction, and induction by no means of the most obvious kind. Far from

LOGIC

being the first induction we make, it is one of the last, or at all events one of those which are latest, in attaining strict philosophical accuracy.' If, then, logic be a science at all, it can be so only as enabling or helping us to ascertain and understand the phenomena which surround us; but Mr. Mill is careful to add, 'When in the course of this enquiry I speak of the cause of any phenomenon, I do not mean a cause which is not itself a phenomenon. I make no research into the ultimate or logical cause of anything: the causes with which I concern myself are not *efficient* but *physical* causes.' If, then, the Aristotelian syllogism is an admirable security for our reading rightly the records of past generalisations, induction is of even greater importance as enabling us to discover and prove the general proposition on which syllogism is founded; hence 'a complete logic of the sciences would be also a complete logic of practical business and common life.' Induction, then, completely reversing the Aristotelian order in the dictum *de omni et nullo*, 'is that operation of the mind by which we infer that what we know to be true in a particular case or cases, will be true in all cases which resemble the former in certain assignable respects.' As it is strictly a process of inference from the known to the unknown, any process in which, as in the Aristotelian syllogism, the conclusion is no wider than the premisses from which it is drawn, does not fall within the meaning of the term; and further, as induction is concerned solely with facts, every well-grounded inductive generalisation must be 'either a law of nature or a result of the laws of nature, capable, if those laws are known, of being predicated from them.' Hence it follows that 'the problem of inductive logic may be summed up in two questions: How to ascertain the laws of nature? and how, after having ascertained them, to follow them on to their results?' Mr. Mill lays down five canons to be observed in the task of singling out from among the circumstances which precede or follow a phenomenon, those with which it is really connected by an invariable law.

I. *Method of Agreement*.—If two or more instances of the phenomenon under investigation have only one circumstance in common, the circumstance in which all the instances agree is the cause (or effect) of the given phenomenon.

II. *Method of Difference*.—If an instance in which the phenomenon under investigation occurs, and an instance in which it does not occur, have every circumstance in common, save one, that one occurring only in the former, the circumstance in which alone the two instances differ, is the effect, or cause, or a necessary part of the cause, of the phenomenon.

III. *Joint Method of Agreement and Difference.*—If two or more instances in which the phenomenon occurs have only one circumstance in common, while two or more instances in which it does not occur have nothing in common save the absence of that circumstance,

LOGOGRAPHY

the circumstance in which alone the two sets of instances differ is the effect, or cause, or a necessary part of the cause of the phenomenon.

IV. *Method of Residues*.—Subduct from any phenomenon such part as is known by previous inductions to be the effect of certain antecedents; and the residue of the phenomenon is the effect of the remaining antecedents.

V. Method of Concomitant Variations.—Whatever phenomenon varies in any manner whenever another phenomenon varies in some particular manner, is either a cause or an effect of that phenomenon, or is connected with it through some fact of causation.

This brief and imperfect sketch of Mr. Mill's system of logic may serve to show some of the many points in which it is at issue with that of Dr. Whately and his followers, and to indicate the grave nature of the controversies on the limits and functions of the science. (See, further, the treatises of Mansel, Shedd, Kerslake, and Archbishop Thomson.)

Logocyclic Curve (Gr. λόγος, and κύκλος, a circle). A name given by Dr. Booth (*Quarterly Journal of Mathematics*, vol. iii.) to a

point F upon the given line $O\mu$. The points m_1, m_2 are obviously inverse points with respect to a circle around F with the constant radius $FO = a$, so that the loxocyclic curve is its own inverse. Its polar equation is easily seen to be $r = a(\sec \theta \pm \tan \theta)$, and its Cartesian equation to the same origin and axis $(x^2 + y^2)(2a - x) = a^2x$. The curve has a double point at O, and an asymptote AB, whose distance from F is double that of the given line $O\mu$. The perpendicular μm to any radius vector at the point μ , where the latter cuts the given line, clearly envelopes a parabola having O for its vertex, and F for its focus. If m be the point of contact of μm with this parabola, then the difference between the parabolic arc Om and its protangent $m\mu$ will be the logarithm of the corresponding radius vector Fm_1 or Fm_2 . Many other interesting properties of the curve are given in Dr. Booth's paper.

Logography (Gr. λόγος, and γράφω). A system of taking down the words of an orator without having recourse to shorthand, which was put in practice during the French revolution. Twelve or fourteen reporters were seated round a table. Each had a long slip of paper, numbered. The writer of No. 1 took down the

first three or four words, and as soon as they were spoken gave notice to his neighbour by touching his elbow, or some other sign; No. 2 passed the sign to No. 3, and so on; until the first line of each slip was filled; No. 1 then began the second line: thus all the twelve or fourteen slips, when filled, being arranged parallel to each other, formed a single page. This mode required great attention and quickness, and was not found to answer well in practice. It was introduced in the National Assembly in October, 1790, the expenses being paid by the civil list; and continued until August 10, 1792, when Louis XVI. and his family, taking refuge from insurrection in the assembly, occupied the box of the logographers. After that time it was not used. (*Dictionnaire de la Conversation.*)

LOGOGRAPHY, LOGOTYPES. [LIGATURES.]

Logogryph (Gr. *λόγος*, and *γρίφος*, a riddle). A species of riddle in vogue among the French (whose language is peculiarly adapted to it), in which the original word (whole) is to be discovered by guesses at other combinations of letters included in it. Thus, the word *plate* includes the various combinations tale, teal, pate, peat, peal, pale, leap, &c.

Logwood. The wood of the *Hæmatoxylon campechianum*, a tree growing in many parts of the West Indies and on the adjoining continent. It is employed in dyeing and calico-printing for the production of reds, blacks, drabs, and several compound colours. Its colouring principle has been termed *hæmatine*. An extract of logwood is used in medicine as an astringent. [HÆMATOXYLON.]

Lolmic (Gr. *λοιμικός*, pestilential). Relating to the plague or contagious disorders.

Lok or Leki. In Northern Mythology, the name of a malevolent deity; corresponding to the Ahirman of the Persians, who is represented to be at war with both gods and men, and originating all the evil with which the universe is desolated. In the *Edda* (the great poem of the Norwegian nations) he is described as the great serpent which encircles the earth, and as having given birth to Hela, or Death, the queen of the infernal regions. [VEITRA.]

Loligo. The squid, or sea-pen cuttle fish; commonly found on our coasts. [SEPIADÆ.]

Löllingite. A name given to Leucopyrite, after one of its localities, Löling in Carinthia.

Lolium (Lat.). A genus of grasses, comprising, along with *L. perenne* and *L. italicum*, which are two of our best pasture and fodder grasses, one of the few deleterious grasses, *L. temulentum*, or Darnel, the seeds of which, ground up with corn, and eaten, produce poisonous effects.

Lollards. A class of persons in Germany and the Netherlands who professed, in the fourteenth century, to undertake spiritual offices in behalf of the sick and dead, and succeeded in attracting the attention and love of the mass of the people when they were in a great measure alienated from the secular and regular clergy by their general indifference and neglect. The

origin of the name has been much disputed; but the enquiries of Mosheim seem to show that it is compounded of the German words *lallen* (identical with the *lallare* of the Romans and the *lull* of our own language, signifying to sing in a murmuring strain) and *hard*, a common affix, as in the somewhat similar word *beghard*. A Lollard, therefore, meant one in the habit of singing the praises of God, or funeral dirges and the like. The Lollards, however, were accused—probably through the spite of the mendicant friars and others whose neglected duties they zealously performed—of holding many heretical opinions. Their reforming views may have been violent; but the charges made against them of vicious habits appear to rest upon no authentic grounds. The term was afterwards applied by the partisans of the church to the heretics and schismatics of the day generally; and the followers of Wicliffe in England are frequently stigmatised under the name of Lollards.

Lombard. A term anciently used in England for a banker or money-lender. The name is derived from the Italian merchants, the great usurers or money-lenders of the middle ages, principally from the cities of Lombardy, who are said to have settled in London in the middle of the thirteenth century, and to have taken up their residence in a street in the city which still bears their name. Stowe, in his *Survey of London*, says, 'Then have ye Lombard Street, so called of the Longobards and other merchants, strangers of diverse nations, assembling there twice every day. The meeting of which merchants there continued until December 22, in the year 1668; on the which day the said merchants began to make their meetings at the Bursse, a place then new builded for that purpose, in the ward of Cornhill, and was since, by her majesty Queen Elizabeth, named the Royal Exchange.' (P. 202.)

Lomentum (Lat.). In Botany, a fruit similar to a legume, excepting that it is contracted in the spaces between each seed, and there separates into distinct pieces; or is indehiscent, but divided by internal spurious dissepiments, whence it appears at maturity to consist of many articulations and divisions. It occurs in the genera *Ornithopus*, *Hidysarum*, &c.

Lonchidite (Gr. *λόγχη*, a spear). A variety of Iron Pyrites, found in small thin tin-white crystals.

London Clay. The name commonly given to a part of the older tertiary deposits of the neighbourhood of London, occupying a kind of trough-shaped depression between the chalk hills of Hertfordshire and Surrey. From the researches of Mr. Prestwich it is clear that the London tertiaries may with advantage be regarded as a distinct group, forming the lower member of the Eocene or lower tertiary series. The whole group contains at least 500 species of organic remains, of which nearly four-fifths are peculiar and characteristic. It underlies the *Bracklesham series* in England, and the *Calcaire grossier series* of Paris.

LONG

The London clay, one of the most important members of this group, is persistent over a large area, and everywhere maintains throughout its mass a nearly uniform mineral character. It is not unconformable with the overlying beds, but does not pass into them. It is thickest in Kent and Essex, and becomes thinner towards the west and south-west. Its beds are remarkably rich in various kinds of fossils, including some birds, many reptilian species, and more than fifty determined species of fishes, of which a large proportion are *Ganoid* species. It also contains a rich variety of fossil fruits of a sub-tropical character. The greatest thickness of clay is in Sheppey, where it amounts to 480 feet. The beds of the plastic clay underlie the London clay.

Long. A musical character of this form \square , the length of which in common time is equal to four semibreves or eight minims.

Long Boat. A large and strong boat, formerly the largest carried by a ship; but it has now generally given place to the launch.

Long Primer. In Printing, the name of a kind of type two sizes larger than that used in this work. [TYPE.]

Long-timbers. In Shipbuilding, those timbers in the cantberries which rising from the dead-wood are continued in one piece to the top of the second futtocks.

Longan (its native Chinese name). The fruit of *Nephelium Longanum*.

Longicorns (Lat. *longus*, *long*; *cornu*, *a horn*). The fourth tribe of Coleopterous insects in the system of Latreille; so called on account of the length of the antennæ, which are rarely shorter than the body, and commonly surpass it in length. But this conspicuous character is not the only one which the Longicorn beetles possess in common. In all of them the under part of the three first joints of the tarsi is furnished with a brush; the second and third are cordiform; the fourth is deeply bilobate; and there is a little nodule, resembling a joint, at the base of the last. The *ligula*, placed on a short and transversal *mentum*, is usually membranous, cordiform, emarginate, or bifid; but sometimes is corneous, and forms the segment of a very short and transverse circle. The antennæ are either filiform or setaceous: they are sometimes simple in both sexes, and sometimes serrate, pectinate, or flabelliform in the males. The eyes in some species are rounded and entire, or but slightly emarginate, and in these species the thorax is trapezoidal or narrowed anteriorly; but in most of the Longicorns the eyes are reniform and surround the base of the antennæ.

As the larvæ of a very great proportion of the Longicorns live in the interior of trees, or under their bark, they are destitute of feet, or have but very small ones. Their body is soft, whitish, thickest anteriorly; and the head squamous, and provided with stout mandibles. They do much injury to trees, the large ones particularly, perforating them very deeply, and sometimes drilling them in every direction. Some of them attack the roots of plants.

LONGITUDE

The abdomen of the female Longicorn is terminated by a tubular and horny ovipositor. These insects produce a small sharp sound, by rubbing the pedicle of the base of their abdomen against the interior of the parietes of the thorax.

Longipalps. The name of a family of Brachelytrous Coleopterans, or short-winged beetles, which have the maxillary feelers almost as long as the head.

Longipennates (Lat. *longus*, and *penna*, *a wing*). A family of swimming birds, comprehending those in which the wings reach as far as or beyond the tail; as the tropic bird, albatross, &c. They are all denizens of the high seas, and from their powers of flight are to be met with in various latitudes. The hind toe is free or wanting. The beak is hooked or pointed at the tip.

Longirosters (Lat. *longus*, and *rostrum*, *a beak*). The name of a tribe of Grallæ, or wading birds, including those in which the beak is remarkable for its length and tenuity, and by the high sensibility of its tip is well adapted for searching or probing in mud or sand for worms or insects. The different gradations in the form of the bill serve to divide the Longirosters into families and genera.

Longissimus Dorsi. A muscle of the back, which assists others in keeping the spinal column erect.

Longitude (Lat. *longitudo*). In Astronomy, this term has two different significations, as it is applied to a celestial or a terrestrial object. The longitude of a heavenly body is the arc of the *ecliptic* intercepted between the vernal equinox and a great circle perpendicular to the ecliptic passing through the body. It is reckoned eastward all round the sphere, from 0° to 360°. The longitude and latitude of a celestial object, having reference to the ecliptic, and not to the plane of the earth's diurnal motion, cannot be directly observed. The elements necessary for determining the place of a star, which are given directly by observation, are its right ascension and declination, from which the longitude and latitude must be calculated by the rules of spherical trigonometry. In the planetary theory, however, it is convenient to refer the motion of a planet to the plane of the earth's orbit, or to make the longitude and latitude the coordinates of its motion. But the places of the stars are always defined, by modern astronomers, by means of their right ascensions and declinations.

The longitude of a place on the earth is the arc of the *equator* intercepted between the meridian of the place and some conventional fixed meridian, which is regarded as the origin from which the measures are reckoned. Terrestrial longitudes and latitudes correspond to right ascensions and declinations in the heavens: with this distinction, however, that the right ascensions are always reckoned from the vernal equinox, or point in which the equator intersects the ecliptic easterly from 0° to 360°; whereas the longitudes are reckoned by different

LONGITUDE

geographers from different points, selected for some local reason, there being nothing connected with the earth's diurnal rotation which can render one point of the equator more convenient than another. Right ascensions are also reckoned in the same direction (eastward) round the complete circumference; while geographical longitudes are reckoned both eastward and westward, 180° each way.

The parallels of latitude on the earth are distinctly marked out by the diurnal circles described by the stars, and consequently latitude can always be determined by direct observation of the heavens; but the case is entirely different with respect to longitude; for to observers situated under the same parallel of latitude, but under different meridians, the heavens present exactly the same aspect, and there is nothing whatever to indicate any difference of locality. Longitude, therefore, cannot be measured by direct observation; it can only be inferred from the measurement of intervals of time to which it is proportional. In the course of a sidereal day the rotation of the earth brings successively every different meridian under the same star; and, the rotation of the earth being perfectly uniform, it follows that the angular distance of any two meridians will be the same part of 360° that the interval of time which elapses between their coming to the same star is of twenty-four hours. For example, if a star pass the meridian of a place A at a certain moment, and that of B exactly one hour of sidereal time later; then the difference of longitude between A and B is the twenty-fourth part of 360° , or 15° , and the longitude of B is 15° west of A. The determination of longitudes consequently resolves itself into the measurement of time; and as the time, or the instant of mean noon, at any place can always be found without difficulty, if any observer at one place can by any means determine the precise hour it is at any other place at the same instant, he has then determined the difference of longitude between the two places. Of the various methods by which differences of longitude may be determined, the simplest and most obvious is that of transferring chronometers from one place to another. Suppose two observers, at the distant stations A and B, each to regulate his clock according to the true sidereal time of his station; and suppose a chronometer, also regulated to true sidereal time, to be compared with the clock at A, and then transported, without suffering any change of rate, to B—the difference of the two clocks would thus be exhibited; and this difference is exactly the time occupied by the equinoctial point, or by any star in passing from the meridian of A to that of B; or it is the difference of longitude of the two places expressed in sidereal hours, minutes, and seconds. Were chronometers perfect, nothing more complete and convenient could be desired; but this unfortunately is even now very far from being the case, and until within a comparatively very recent time the practical determination of the

longitude by means of chronometers could not be attempted.

Another method of determining the difference of longitude between two places, is by telegraphic signals. This method, though, from its nature, of limited application, is susceptible of great accuracy. The explosion of a rocket, the flash of gunpowder in an open dish, the extinction of a bright light, &c., are instantaneous phenomena which can be seen at great distances and noted with the utmost precision. A signal of this kind, made at a station visible from two observatories, must be seen at the same absolute instant of time from both; and the time marked by the clock of each observatory at this instant being noted, the difference of their local times, and consequently the difference of their longitudes, becomes known. This method is chiefly practised in connection with geodetical operations for measuring degrees of longitude on the earth's surface, and is perhaps the best that can be adopted for determining the difference of longitude between two observatories situated at no very great distance from each other. By means of intermediate signals, and observers suitably disposed between each, it may also be applied to transfer the time from one place to another, when the distance is too great to allow an artificial signal of any kind to be seen from both. (*Phil. Trans.* 1826.)

When the distance between two places is very considerable, artificial signals cannot be employed, and it becomes necessary to have recourse to the methods furnished by astronomy. These are principally the following:—

1. *Eclipses of Jupiter's Satellites.*—These phenomena are visible at the same instant of absolute time to all places on the earth; and although they are not susceptible of being observed with rigid exactness, this method is much used by travellers, though for fixed observatories the mean of a long series should be taken. The uncertainty is least in the case of the first satellite, on account of its quick motion; and as the eclipses of this satellite occur much more frequently than those of the others, the observations are chiefly confined to it. The times of the eclipses of the three first satellites are given in the *Nautical Almanac*; so that an observer at any part of the world, who observes one of these eclipses, has only to compare his local time with that assigned to the phenomenon in the almanac in order to determine the distance of his meridian from that of Greenwich.

2. *Occultations of Fixed Stars by the Moon.*—This method consists in observing accurately the time at which a certain fixed star disappears behind the disc of the moon, or reappears after having been occulted. The first of these phenomena is called the *immersion* of the star, the second the *emersion*. But, on account of the moon's parallax, the immersion or emersion of a star behind her disc does not take place at the same absolute instant to observers on different parts of the earth; a calculation is therefore necessary to clear the obser-

LONGITUDE

vation of parallax, or to determine the time at which the phenomenon would have occurred if it had been seen from the centre of the earth. The length of the calculations by which the longitude is deduced is a disadvantage which attaches to this method. [OCULTATION.]

3. *Eclipses of the Sun.*—The longitude is deduced from the observation of solar eclipses, in the same manner, and by precisely the same sort of calculations, as from the occultation of fixed stars. An eclipse of the sun is, in fact, an occultation; but these phenomena occur so seldom at any particular place, that they afford little assistance in the determination of longitudes. It may be remarked that the irregularities of the border of the moon's disc render the instant of the commencement or end of a solar eclipse, as also of the immersion or emersion of a fixed star, somewhat uncertain. But this uncertainty is corrected, or rather avoided, by measuring with a micrometer the distance between the two cusps, which, shortly after the commencement of the eclipse, appear as brilliant points, sharp and well defined. Knowing the distance of the cusps, or length of the chord, and also the semidiameters of the two bodies, the true distance of their centres at the instant the measure was taken can be calculated without much difficulty. As this measurement can be executed with much precision, and can also be repeated frequently during the progress of the eclipse, the phenomenon of a solar eclipse affords one of the most certain methods of determining a longitude which can be practised. [ECLIPSE]

4. *Transits of the Moon.*—This method is founded on the moon's rapid change of place among the stars, which becomes very sensible even in short intervals of time. Suppose an observer at the station A to determine the sidereal time of the transit of the moon's centre over his meridian; and suppose another observer at B, to the west of A, also to denote the sidereal time of the same transit; if the moon's right ascension had in the interval undergone no change, the sidereal times marked by the two observers would have been the same; but as the right ascension has increased, while the moon was passing from the meridian of A to that of B, the sidereal time of the transit at the latter place will be increased; and, supposing the change of right ascension to be uniform, the difference of the times of transit will be proportional to the difference of meridians. The chief objection to this method is, that any minute error in the adjustment of the transit instrument or rate of the clock is thrown upon the longitude, on which it produces a very sensible effect. The method can, therefore, only be safely practised at fixed observatories with the best instruments.

5. *Moon-culminating Stars.*—This method has been proposed for the sake of eluding the effect of minute instrumental errors, which render the method last described so difficult. A star is chosen which *culminates* (that is, comes to the meridian) at nearly the same time with the

moon, and which has very nearly the same declination; so that it may be seen in the field of view without altering the position of the transit instrument. The transit of the star, as well as the transit of the moon's limb, is observed at both stations (or at least observed at the one station, and calculated for the other whose meridian is known), and the difference of sidereal time between the two transits noted at each. This difference, in consequence of the moon's motion in right ascension, is not the same at both stations; and its variation gives the difference of the longitude. By this means any error in the position of the transit instrument affects the star and the moon both alike; but it is erroneous to suppose that the method is independent of accuracy in the adjustment of the transit instrument; for if the instrument is out of the meridian, the resulting longitude will be in error by the amount of the moon's variation in right ascension during the corresponding interval.

6. *Lunar Distances.*—None of the methods which have yet been described (excepting that by chronometers) can be very conveniently applied to the important problem of determining the longitude of a ship at sea. In this case, no fixed or meridian instrument can be employed; and the observer can only measure the apparent distance of the moon's limb from a fixed star or planet with a sextant, or some reflecting instrument which can be held in the hand. For the purpose of rendering this method available to seamen, the distance of the moon from certain fixed stars is computed (several years previously) for every three hours of Greenwich time, and published in the *Nautical Almanac*. The moon's distance from one of these stars being observed on board a ship, and corrected for refraction and parallax, and the apparent time at the place and moment of observation being determined in the usual manner by the altitude of the sun or a known star, the difference between the apparent time of the observation and the apparent time at Greenwich corresponding to the same distance, interpolated from the *Nautical Almanac*, gives the longitude of the ship. The longitude may also be determined by azimuths of the moon or by its altitude, either absolute or relatively to a star observed with a zenith telescope. [LUNAR METHOD.]

In the projection of maps and charts it is necessary to assume a point of the equator as the origin of the longitudes. The meridian passing through this point is called the *first meridian*; and as its selection is perfectly arbitrary, it has been placed by different geographers at various parts of the earth—a circumstance which occasions some inconvenience in consulting works of geography. Modern geographers usually assume the meridian of the capital of their own country as the first meridian. English writers generally adopt the meridian of the Greenwich Observatory, for which the *Nautical Almanac* is computed; the French that of the Observatory of Paris.

LONGUS COLLI

[MERIDIAN.] Ptolemy, and the most celebrated of the ancient geographers, placed the first meridian at the Fortunate Islands (now the Canaries), which they conceived to be the utmost boundary of the habitable earth. The Arabian astronomers also counted the longitude from the Fortunate Islands; and many of the modern geographers have counted from the island of Ferro, one of the most westerly of the Canaries. The reason for fixing on this point was probably that as there was no land known to the west of the first meridian, the longitudes of all places would be reckoned in the same direction, or there would be no west longitude. The discovery of America destroyed the force of this reason. The inconvenience of counting in two directions is not very great; but it might be avoided by reckoning the longitude all round the circle to 360°, which would undoubtedly be an improvement on the present method.

Degrees of Longitude.—The figure of the earth being spheroidal, the degrees of longitude diminish as we proceed from the equator towards either pole. For the law of their variation, and their lengths on the different parallel circles, see DEGREES.

Geocentric Longitude is the longitude of a planet as seen from the earth; that is, the point of the ecliptic to which it perpendicularly corresponds as seen from the centre of the earth.

Heliocentric Longitude is the longitude of a planet as seen from the sun. [GEOCENTRIC; HELIOCENTRIC.]

Longus Colli. The name of a pair of muscles of the neck: when one contracts, it moves the neck to one side; when they both act, the neck is bent forwards.

Lonicera (after Adam Lonicer, a German botanist). The botanical name of the Honeysuckle genus, of which many species occur in our gardens.

Loof. In a Ship, that part of the bow where the timbers begin to cant or curve in towards the stem.

Loom. [WEAVING.]

Looming. The indistinct and magnified appearance of objects seen in particular states of the atmosphere. [MIRAGE.]

Lopholes. In Fortification, apertures in the walls of fortified places, in stockades, &c., through which musketry fire may be directed upon the exterior ground. They correspond for musketry fire to *embrasures* for cannon. They were formerly made in the battlements of castles, to enable arrows and javelins to be shot from within.

Lopez. *Radix Lopeziana.* The name of the root of an unknown tree, supposed to grow at Goa: it is said to be remarkably effective in checking diarrhoea.

Lophine. A crystalline substance formed by the destructive distillation of AMARINE; it has also been called *pyrobenzole*. The formula assigned to it is $C_{12}H_7N_3$.

Lophiodon (Gr. *λόφος*, a crest, and *ὀδόν*, tooth). A genus of fossil Perissodactyle Mam-

LORANTHACEÆ

malia, remains of which have been found in the Eocene strata. The teeth present annectant affinities between *Tapirus* and *Rhinoceros*. The last two premolars are more simple in *Lophiodon* than in *Tapirus*; the inner side exhibiting one cone in the former, and two in the latter genus. It was, however, more nearly allied to *Tapirus* than to *Palæotherium* and *Rhinoceros*.

Lophiracæ (Lophira, one of the genera). A natural order of hypogynous Exogens, belonging to the Guttiferæ alliance. *Lophira* is the sole genus. They are tropical African trees, of no special interest.

Lophobranchiæ (Gr. *λόφος*, and *βράγχια*, gills). An order of osseous fishes, comprehending those in which the gills are in the form of small tufts, and disposed in pairs along the branchial arches; as in the pipe-fish and hippocamp.

Lophote. A variety of Ripidolite from Zillerthal in the Tyrol.

Lophotes (Gr. *λόφος*). A genus of Tænioid fishes, characterised by a short head, surmounted by a high osseous crest, to the summit of which a long and stout spine is attached, bordered behind with a membrane and a low fin, of which the rays are nearly all simple, and which extends from the occipital spine to the point of the tail; this is terminated by a distinct but very small caudal fin.

Lophyropods, Lophyropoda (Gr. *λόφος*, and *πούς*, a foot). The name of a section of Entomostracous Crustaceans, comprehending those species which have cylindrical or conical ciliated or tufted feet.

Lopping. In Arboriculture, the cutting off all the branches of a tree for the sake of the profit to be derived from them; as contrasted with pruning, by which some of the branches are cut off for the sake of the tree. The lopping of a tree, however, does not include the cutting off of the crop or leading shoot; and hence, when timber trees are sold, the purchaser bargains to take them either with or without the lop and crop, as the case may be.

Loranthacæ (Loranthus, one the genera). A natural order of parasitical Exogens included by Lindley in his Asaral alliance. They principally inhabit the equinoctial regions of Asia and America, and are distinguished from *Caprifoliacæ* and all other orders by their parasitical habit, and by the stamens being opposite to the petals. Brown suggests their relation to *Protacææ*; and, upon the whole, the structure of this order appears to be rather that of a polypetalous or apetalous than of a monopetalous order. Schleiden has made the startling assertion that they are gymnospermous. The bark is usually astringent. Their chief peculiarity is their power of rooting in the wood of other plants. They effect this when they first germinate by fixing their root upon the bark, and then by slow degrees introducing it into the tissue till they reach the wood, between the wedges of which they slightly insinuate themselves, thus placing their abortive

roots in the line of the current of ascending sap. They are generally beautiful plants, but are scarcely capable of cultivation. Mistletoe is the most northern species of the order.

Lorcha. The name of a coasting vessel used in the Chinese seas.

Lord (A.-Sax. hláf-ord, supposed by some to mean ord, the origin of hláf, loaf, but regarded by others as a corruption of hláf-weard, the warden of bread: Max Müller, *Lectures on Language*, 2d series, p. 255). A title of honour. It may be said to be either a title of hereditary dignity (as lord of parliament); or a title expressing certain powers, as lord of a manor, lord chancellor, lord of the treasury, &c. The eldest sons of earls, and all the sons of dukes and marquises, are styled lords by courtesy.

Lord Advocate of Scotland. [ADVOCATE.]

Lord Keeper. [CHANCELLOR; KEEPER.]

Lord Privy Seal. [SEAL.]

Lord's Supper, The. [EUCHARIST.]

Lord-Lieutenant of Ireland. The chief executive officer of the Irish government, representing in some respects the person of the king. The first viceroy or lieutenant of Ireland appears to have been appointed in the reign of Henry II.; and by Acts of Parliament passed in the reigns of Richard III. and Henry VIII. provision was made for the election of a governor by the chancellor, treasurer, or other high officers of the government, on the death or resignation of a lieutenant, until the king's pleasure were known. The chief officer in Ireland has been variously styled at different times; as custos or keeper, justiciary, warden, procurator, seneschal, constable, deputy, and lieutenant. He is appointed by letters patent durante bene placito. He has a council, composed of the great officers of the crown in Ireland and others appointed by the crown. He corresponds with the secretary for the home department; but the management of the affairs of the Irish government in London is chiefly intrusted to the secretary for Ireland, who is also chief secretary of the lord-lieutenant. He has also a household, consisting of a private secretary, steward, comptroller, chamberlain, gentleman usher, master of the horse, and subordinate officers. His salary has been usually 20,000*l.* per annum.

Lords-Lieutenant of Counties. In England and Wales, officers appointed by the king, and intrusted by parliament with full power and authority to call together, arm, and array the militia, and cause them to be trained and exercised once every year. Each may appoint twenty or more deputy-lieutenants, who must have 200*l.* a year freehold estate; except in the Welsh and some small English counties, where the qualification is only 150*l.* The lord-lieutenant also nominates officers in the militia and yeomanry: but the names both of deputy-lieutenants and officers must be laid before the king; and if he, within fourteen days, expresses disapprobation, the commissions do not issue.

Lordship. [LEET.]

Lore (Lat. lorum, a thong). In Ornithology, signifies the space between the bill and the eye, which is bare in some birds, as in the great crested grebe; but is generally covered with feathers. In Entomology, the term is applied to a corneous angular machine observable in the mouth of some insects, upon the intermediate angle of which the mentum sits, and on the lateral ones the cardines of the maxillare, and by means of which the trophi are pushed forth or retracted, as in the Hymenopterous insects.

Lorica (Lat.; Gr. θώραξ). A cuirass or crest of mail, made of leather and set with plates of metal in various forms, chiefly in rings like a chain, used by the Roman soldiers.

Loricates, Loricata (Lat. lorica). The name given by Merrem to an order of reptiles dismembered from the Sauria of Cuvier, and including those species, as the Crocodile, which are protected by an armour of bony plates.

Lorication (Lat. loricare, to crust over). A term of old Chemistry, signifying the application of a lute or coating to glass and other vessels.

Lorimer (from Lat. lorum). A name formerly given to the makers of bits, spurs, and other articles of iron used for horses.

Loris. [STENOPE.]

Lory. A tribe of birds composed of several genera, closely allied to the Parrots: remarkable for their very soft beaks. They are to be found in most of the islands of the Indian Archipelago, and in Australia.

Lotalite. A greenish-grey mineral found at Peterlow in Finland.

Lote-tree (Gr. λωτός). Of this there were two kinds: the one a small plant, from which the *Lotophagi* derived their name; the other a tree with cut leaves and very hard wood. The former is reputed to be the *Zizyphus Lotus*, the latter the *Celtis australis*. The true Lotus of the ancients has been, however, with more probability referred to *Nitraria tridentata*. In the Hindu Mythology, the Lote-tree is regarded as the symbol of creation. [LOTOPHAGI.]

Lothian. A name common to that part of Scotland which stretches along a considerable part of the southern shores of the Frith of Forth, and comprehends three counties, Haddingtonshire, Edinburghshire, and Linlithgowshire; otherwise called East, Mid, and West Lothian. The etymology of the name is doubtful. Lothian was taken possession of by the Saxon invaders A. D. 450, and became the scene of contest between the Saxon-Gaels and Scotch-Irish, and was at length ceded to Malcolm II. in 1020. Lothian was considered as a country wholly distinct from Scotland in the reign of David I., and the period of its incorporation with the rest of the country is assigned to the eleventh or twelfth century.

Lotion (Lat. lotio). A mixture of different ingredients, or a solution of various medicinal substances, in water or other menstrua, designed for external application. Indolent ulc and tumours require stimulating lotions; whereas

sedative and narcotic mixtures are used to alleviate pain.

Lotophagi (Gr. *λωτοφάγος*, a lotus-eater) In Homeric Mythology, the name of the people inhabiting a country to which Ulysses was carried (*Odys.* ix. 82) while trying to double Cape Malea in the Peloponnesus. (Gladstone's *Homer and the Homeric Age*, vol. iii. p. 320.) According to the legend, those who ate the fruit forgot their friends and country, and wished only to remain idle in the land of the Lotus.

Lottery (Ger. *loos*, *lot*). A lottery may be defined as a game of hazard, in which small sums are ventured for the chance of obtaining a larger value, either in money or other articles. Lotteries are formed on various plans; but in general they consist of a certain number of tickets drawn at the same time, with a corresponding number of blanks and prizes, by which the fate of the tickets is determined. In modern times this species of gaming has been sanctioned at different periods by most of the European governments, as a means of raising money for public purposes. The earliest English lottery of which there is an authentic record was drawn in 1569, when 400,000 tickets were sold at ten shillings each. The prizes consisted chiefly of plate, and the net profits were intended to be appropriated to repairing the harbours of the kingdom and other public works. In 1612 a lottery was drawn for the benefit of the English colonies; and, in the course of the same century, the desire for embarking in speculations of this kind gave rise to so many private undertakings, many of which were formed on the most fraudulent principles, that, in the beginning of Queen Anne's reign, parliament found it necessary to suppress private lotteries 'as public nuisances.' The year 1709 saw the birth of the first state or parliamentary lottery; and from that time down to 1823 they were annually licensed by Act of Parliament, under a variety of regulations. In the very early part of last century the prizes were paid in the form of terminable annuities. Thus in 1746 a loan of 3,000,000*l.* was raised on 4 per cent. annuities, and a lottery of 50,000 tickets, at 10*l.* each; and in the following year 1,000,000*l.* was raised by the sale of 100,000 tickets, the prizes in which were funded in perpetual annuities, at the rate of 4 per cent. per annum. During the same century government constantly availed itself of this means to raise money for various public works, of which the British Museum and Westminster Bridge are well-known examples. But at the commencement of the present century a great repugnance began to be manifested in parliament to this method of raising any part of the public revenue, in consequence of the spirit of gambling which it tended to foster in the great body of the people; and the evil at last became so palpable, that, in the year 1823, the legislature consented to the entire abolition both of state and private lotteries. It would be superfluous to enter into any argument to point out how prejudicial all such establishments must be to public morals, by

giving the countenance of government to a system of gambling, by which the mind is misled from habits of continued industry to dreams of sudden wealth, which, in the great majority of instances, must end in ruin. Those who wish to see the results of this system of finance exhibited in its true colours, will find ample information in the two parliamentary reports presented to the House of Commons on the subject of lotteries in 1808; but the following passage from the *Wealth of Nations* illustrates clearly and forcibly their principle and operation:—

'The world neither ever saw, nor ever will see, a perfectly fair lottery, or one in which the whole gain compensated the whole loss: because the undertaker could make nothing by it. In the state lotteries, the tickets are really not worth the price which is paid by the original subscribers, and yet commonly sell in the market for twenty, thirty, and sometimes forty per cent. advance. The vain hope of gaining some of the great prizes is the sole cause of this demand. The soberest people scarce look upon it as a folly to pay a small sum for the chance of gaining 10,000 or 20,000 pounds; though they know that even that small sum is perhaps 20 or 30 per cent. more than the chance is worth. In a lottery in which no prize exceeded 20*l.*, though in other respects it approached much nearer to a perfectly fair one than the common state lotteries, there would not be the same demand for tickets. In order to have a better chance for some of the great prizes, some people purchase several tickets, and others small shares in a still greater number. There is not, however, a more certain proposition in mathematics, than that the more tickets you adventure upon, the more likely you are to be a loser. Adventure upon all the tickets in the lottery, and you lose for certain; and the greater the number of your tickets, the nearer you approach to this certainty.' (Degerando's *Bienfaisance Publique* l. ii. ch. vi.)

State lotteries were abolished in France in 1836, along with the gambling houses, from which a great revenue had been derived. They still exist in several of the German states. That of Hamburg is established on a comparatively fairer principle than was adopted either in France or England; the whole money for which the tickets are sold being distributed among the buyers, except a deduction of 10 per cent. made from the amount of the prizes at the time of their payment.

Lough. An Irish term, synonymous with the Scotch *loch*, but not with the English *lake*; for loch and lough are applied to designate arms of the sea, as well as collections of fresh water, which *lake* is not.

Louis, St., of France. A royal military order, founded by Louis XIV. in 1693. The badge is a cross of eight points, with fleur-de-lis, and bearing a circular shield containing the effigy of St. Louis.

Louis d'Or. A gold coin under the old system of France, first struck under Louis XIII.

LOUPING-ILL

in 1641, from whom they derived their name. The louis d'ors, says Kelly, coined before 1726, which passed then for 20 livres, were coined at the rate of 36½ per French mark of gold 22 carats fine. From the year 1726 to 1785 louis d'ors were coined at the rate of 30 to the mark of gold; and about this period all the gold coins in France were ordered to be brought to the mint to be melted down; and a new coinage then took place, at the rate of 32 louis d'ors to the mark of the same degree of fineness, with a remedy of 15 grains in the weight, and $\frac{1}{32}$ of a carat in the alloy. The intrinsic value of this new coin was 18s. 9½d. sterling. Louis d'ors were formerly regarded as a current coin in all parts of the Continent; but in England they are sold merely as merchandise, and their value has fluctuated from 18s. 6d. to 21s. sterling.

Louping-ill. The name applied, in the case of sheep and cattle, to the disease known as the Mad Staggers, when it attacks the horse.

Louse. The *Pediculus Hominis* of Linnaeus, a small parasitic apterous insect; well known, and usually found on those individuals who neglect personal cleanliness. It proceeds from a small egg, or *nit*, and is distributed amongst nearly all known domesticated animals; the species, however, differing usually from those found in man.

Louvre. One of the most ancient palaces of France. It existed in the time of Dagobert, as a hunting seat; the woods then extending all over the actual site of the northern portion of Paris, down to the Seine. The origin of its name has not been satisfactorily ascertained. It was formed into a stronghold by Philip Augustus, who surrounded it with towers and fosses, and converted it into a state prison, for confining the refractory vassals of the crown. It was then without the walls of Paris; but on their extension in the latter part of the fourteenth century, it was included in their circuit. Charles V. made additions to it. That part of the palace now called the Vieux Louvre was commenced under the reign of Francis I., after the designs of Pierre l'Escot, abbot of Clugny. When Charles IX. resided in the Louvre, he began the long gallery which connects it with the Tuileries, built for his mother by Philibert de l'Orme: this gallery now holds the celebrated collection of paintings; it was finished by Henry IV. Louis XIV. erected the peristyle that formed the entrance to the Vieux Louvre (since materially altered) from the side of the Tuileries, after the designs of Lemercier. That monarch also gave a beginning to the modern portion of the Louvre, by erecting, after Perrault's design, the great eastern front: and subsequent monarchs have slowly advanced it towards completion, especially Napoleon I. The eastern front exhibits a façade of great beauty, though it is sadly out of harmony with the architecture of the interior and of the inner quadrangle. (See the criticism of Mr. Ferguson in his *History of the Modern Styles of Architecture*.) Of late years,

LOWER EOCENE

the Louvre has been connected with the Tuileries, at an immense expense, but with supreme talent, by the late M. Visconti, assisted by M. Lefeuille; and the united palaces form a mass imposing and magnificent in the extreme. Besides the gallery of paintings above mentioned, which contains some of the finest works of art in the world, the Louvre contains a matchless collection of antiquities, and other specimens of art; the collection of Roman and Græco-Roman sculpture, and of Etruscan ornaments, is unrivalled.

Love Apple. The Tomato, *Lycopersicum esculentum*, whose fruit forms an excellent ingredient in soups, sauces, and gravies, and is also extensively used in various other ways.

Love, Family of. A sect of fanatics in the sixteenth century, holding tenets resembling those of the early Anabaptists. There is a proclamation against them by Queen Elizabeth, dated from her manor of Richmond, 1580.

Love Feasts. Religious meetings held quarterly by the Methodists, to which members of their church alone are admitted, and that only on presenting a ticket or a note from the superintendent. They are retained in imitation of the AGAPÆ [which see] held by the early Christians.

Low Sunday. In Ecclesiastical Antiquities, the Sunday next after Easter has been popularly so called in England; perhaps by corruption for *close* (Pascha clausum, *close of Easter*, one of the many names by which it was known in the Christian church).

Lüwette. A yellowish or reddish mineral product, found at Ischl in Austria. It is a sulphate of magnesia and soda.

Lower Empire. A name sometimes applied to the Roman empire, from the removal of the imperial seat to Constantinople down to its extinction on the capture of Constantinople by the Turks in 1453.

Lower Eocene. The Lower Eocene deposits are best developed in the London and Hampshire basins, and can be studied there in great detail. They are very rich in fossils, including a great variety of plants, of which the fruits alone remain, and many quadrupeds of extreme interest. On the whole, they may be said to underlie the great Paris series, with which they were long compared.

The following is the division of these beds suggested by Mr. Prestwich as best showing the position of the deposits in England:—

UPPER SERIES	{	London clay	{	Upper
		Basement bed of the London clay		Middle
LOWER SERIES	{	Woolwich and Reading series	{	Lower
		Thanet sands		

Lower Eocene formations under various names are known in many parts of Europe, Asia, and both North and South America, and range into North Africa. The NEOMULTRIC FORMATION is

LOWER GREENSAND

one of the most important representatives. The Monte Bolca and Mount Lebanon beds, celebrated for their fossil fish remains, are at the bottom of these Tertiaries. So also are the *Santa limestone* of North America and some of the green earths of New Jersey U.S. The older tertiaries as a group are very rich in organic remains. [EOCENE; LONDON CLAY.]

Lower Greensand. The name given by English geologists to the lower division of the Cretaceous series of rocks as developed in the south-eastern part of the British Islands. The name *greensand* was originally given to the sands beneath the chalk, because in many places, though red in colour, they are found to be full of green particles, owing to the presence of scales of silicate of iron. Beds of this kind are developed very largely in our own islands. Deposits of the same age are found also on the Continent, especially in the north of Switzerland at Neuchâtel. These beds are typical; and under the name *Neocomian*, which probably includes some part of our Wealden period, important deposits occur in Switzerland.

The lower greensand is rich in fossils, many of them very characteristic. The *Perna mullati*, a large bivalve shell, is common in the typical beds. Shells of cephalopodous molluscs, varying greatly in form, abound in the rocks of this period.

The Isle of Wight presents admirable sections of the lower greensand, and serves to connect the beds known under this name with the typical Neocomian deposits. [NEOCOMIAN]

Löwigite. A variety of Alum-stone found at Tolfa in Italy and Tabræ in Siberia, and differing from ordinary Alum-stone only in containing a less amount of water. Named after Löwig, by whom it was analysed.

Loxia (Gr. *λοξός*, *crooked*). A genus of Conirostral Passerine birds, characterised by having a compressed beak, and the two mandibles so strongly curved that their points cross each other, sometimes on one side, sometimes on the other. The crossbill (*Loxia curvirostra*) is the type of this genus.

Loxoclase (Gr. *λοξός*, and *κλάω*, *I break*). The name given by Breithaupt to the Felspar which occurs with Pyroxene in the Laurentian rocks of Hammond, St. Lawrence county, New York. It has the cleavage, density, and composition of Orthoclase, and is remarkable for the large amount of soda which it contains.

Loxodromic Curve (Gr. *λοξός*, and *δρομος*, *a course*). A curve which cuts at a constant angle all the lines of curvature of a surface which belong to one and the same system. In the case of a surface of revolution, the trajectories of the meridian lines are loxodromic curves. A ship sailing always towards the same point of the compass, or on the same rhumb, describes a loxodromic curve; it is manifestly a kind of spiral which approaches the pole asymptotically. The differential equation of a loxodromic curve on the sphere is easily found. In fact, if ϕ be the arc of the meridian intercepted between any point of the curve and the pole, and λ the lon-

LUCANIDÆ

gitude of that point, then the infinitely small arc of the parallel of latitude corresponding to an increment of the curve is $d\lambda \sin \phi$, and the differential of the co-latitude is $d\phi$; but, because the curve cuts all the meridians under the same angles, the variation of the parallel of latitude corresponding to an increment of the curve is proportional to the variation of the co-latitude; consequently $a d\lambda \sin \phi = d\phi$, or $a d\lambda = \frac{d\phi}{\sin \phi}$, which is the differential equation

required. By integration, the equation of the loxodromic curve is at once found to be $\tan \frac{\phi}{2} = c e^{\lambda}$, where c is a new constant. From

this it is at once manifest that the stereographic projection of a loxodromic curve on the sphere is a logarithmic spiral, the centre of projection being at the pole opposite to the one from which the angles ϕ are measured.

Lozenge (Fr. *losange*). In Heraldry, a bearing in the shape of a parallelogram, with two obtuse and two acute angles. The arms of maidens and widows are borne on shields of this shape.

Lozenge. In Mathematics, a synonym for *rhombus*, being an oblique-angled equilateral parallelogram.

Lozenge. In Pharmacy, a medicinal substance made up into a small cake, to be gradually dissolved in the mouth. Sugar, gum, and starch are the usual inert parts of lozenges; and minute quantities of active substances are added, according to the purposes for which they are intended: such as ipecacuanha or squills, for pectoral lozenges; extract of poppies or opium, for sedative lozenges; cayenne pepper as a stimulant; oil of peppermint as an antispasmodic, &c.

Lubber's Hole. On Shipboard, an entrance to the top, by which it is reached without passing over the futtock shrouds. It is the easier though slower way, and is regarded by sailors as only worthy of a lubber.

Lubricator (Lat. *lubricus*, *slippery*). An arrangement for lubricating the bores of rifled guns, and thus removing the solid residue from the powder which would otherwise be left in the bore, and clog the grooves. It consists, in our service, of a copper wad, containing equal parts of tallow and oil, next the projectile, then a felt wad, and then a millboard disc, all joined together. The explosion of the charge drives the copper wad against the projectile, and releases the lubricant; which the felt wad, acting as a mop, wipes up and carries forward.

In Machinery, the term *lubricator* is applied to the arrangement by which the bearings of the engine are preserved from the effects of friction by means of oil or grease.

Lucanidæ (Gr. *λύκος*, *a wolf*; also the name of an insect). A family dismembered from the Linnæan genus *Lucanus*, and including the insects which, in addition to the comprehensive characters of the original genus, present antennæ strongly geniculate, glabrous, or but slightly

LUCANUS

pilose; the labrum very small, or confounded with the epistome; maxillæ terminated by a membranous or coriaceous, silky, penciliform lobe; edentate, or with one tooth; and a ligula either entirely concealed or incorporated with the mentum, or divided into two narrow, elongated, silky lobes, extending more or less beyond the mentum. The scutellum is situated between the elytra. The stag-beetle, *Lucanus cervus*, &c., is the type of this family. The subgenera are *Esalus*, *Lamprina*, *Sinodendrum*, &c.

Lucanus. A Linnæan genus of Coleoptera, forming the type of a tribe of Lamellicorn beetles (*Lucanina*) in the system of Latreille, by whom it is thus characterised: Antennæ composed of ten joints, the first of which is usually much the longest; the antennal club has its leaflets or teeth arranged perpendicularly to its axis, in the manner of a comb. The mandibles are always corneous, and most commonly exhibit a sexual superiority of development and peculiarity of form in the males. The maxillæ are generally terminated by a narrow, elongated, and silky lobe; but sometimes are entirely corneous and dentated. The ligula in most of the *Lucanines* is formed of two small silky pencils, projecting more or less beyond an almost semicircular or square mentum. The anterior legs in the greater number are elongated, and their tibiæ dentated along the whole of their outer side. The tarsi terminate in two equal and simple hooks, with a little appendage with two setæ between them. The elytra cover the whole of the upper part of the abdomen. The insects thus characterised were first divided by the immediate successors of Linnaeus into two genera, *Lucanus* proper and *Passalus*, both of which are now elevated to the rank of families, and subdivided into numerous subgenera. [LUCANIDÆ; PASSALINÆ.]

Luceres (Lat.). In Roman History, the name given to a division of the Roman populus or patricians. Livy (i. 13) speaks of the origin of this name as unknown, but describes the Luceres with the Ramnenses and Titenses as centuries of knights. [EQUITES.] Elsewhere (x. 6) he speaks of them as being the three ancient tribes. (Sir G. C. Lewis on *the Credibility of Early Roman History*, ch. xi. sec. i.)

Lucern. The *Medicago sativa*, a well-known plant of the natural family *Leguminosæ*. There are many species of *Medicago*, but of these the artificial grass, called Lucern, is most deserving of notice. This plant was in high estimation among the ancients; and its nutritious qualities, easy cultivation, rapid growth, and luxuriant properties, have placed it in the first rank of vegetable food for cattle, even in the present times. 'Lucern,' says an old writer, 'is commended for an excellent fodder. . . . There is not any pulse or other feeding which is more agreeable or more precious for feeding beasts than lucerne: so that it may seem to spring out of the earth. . . . as a more especial favour from God, not only for nourishing and fattening herds of cattle, but also to serve as a physic for beasts

LUCIFERIANUS

that are sick.' (*Country Farm*, 3rd edit. fol. 1616, p. 364.) Those who wish to see the properties of this plant fully developed, and its history traced from its discovery during the Persian expedition under Darius to its subsequent introduction successively into Greece, Italy, Spain, France, and Germany, down to its arrival in England, will find ample details in the learned *Essays on Husbandry* by the Rev. Walter Harte (London 1770). The origin of the term *lucerna* is involved in obscurity. Some authors have derived it, naturally enough, from the canton in Switzerland of that name; but from the account given by Mr. Harte of the history of this plant, it does not appear either that Switzerland was particularly famous for producing it, or that the northern or western nations of Europe received it thence. It is cultivated successfully in the lowland part of Essex, where a deep calcareous loam and a favourable climate combine to make it a most productive forage crop.

Lucernaria (Lat. *lucerna*, a lamp). A genus of fleshy polypi (*Polypi carnosii*) in the system of Cuvier, characterised by a long and slender pedicle supporting a radiated disc, which sends off numerous tentacula united in bundles. Cuvier regarded the *Lucernaria* as being nearly allied to the *Actinæ* or *scapanomones*; but their substance is softer. They emit phosphorescent light.

Lucifer (Lat. *light-bearing*). The morning star. A name given to the planet Venus, when she appears in the morning before sunrise. When Venus follows the sun, or appears in the evening, she was called *Hesperus*, the evening star. These names no longer occur except in the old poets.

Lucifers. This term was originally applied to matches tipped with a mixture of chlorate of potash and sulphuret of antimony which were inflamed by friction upon a piece of emery paper. These have been superseded by a variety of mixtures containing phosphorus. The manufacture of lucifers now forms a vast trade, which in this country alone consumes upwards of eight tons of phosphorus and twenty-six tons of chlorate of potash in tipping them. The process of making them is almost wholly performed by machinery. It has been found that the ill effects caused by the employment of common phosphorus on the health of the workmen may be prevented by using in its stead the red or amorphous phosphorus, which with manganese and glue is made into a friction-paste for covering the side of the boxes. Such matches, as not being affected by accidental friction, and as being free from poison, are called safety matches.

Luciferians. The name of a sect of schismatics, so called from Lucifer, bishop of Cagliari, in the fourth century, who refused to hold any communion with the clergy who had conformed to the Arian doctrines, and whom a synod at Alexandria, A.D. 362, had determined to readmit into the church on condition of an open acknowledgment of their

LUCINA

errors. His followers are little heard of after the time of Theodosius the Great. [SCHISM.]

Lucina. [LUNA.]

Lucullite. A black limestone often polished for ornamental purposes, to which it is said first to have been applied by Lucullus the Roman consul, who originally carried it to Rome from an island in the Nile.

Lucuma (its Peruvian name). A genus of *Sapotaceæ* found in the West Indies and South America, and comprising numerous shrubs or tall trees, one of which, *L. mammosum*, called the Marmalade-tree, is cultivated for the sake of its fruit, which contains a thick agreeably flavoured pulp bearing some resemblance in appearance and taste to quince marmalade.

Ludlow Formation. The upper member of the typical Silurian series in England. It is well developed near the town of Ludlow, and is there recognised by distinct groups of organic remains.

It is subdivided into three principal members, (1) Upper Ludlow sands and shales, (2) Aymestry limestone, and (3) lower Ludlow shales, with concretions of limestone. The whole series is rich in organic remains, many of them characteristic and easily recognised. Certain groups of *trilobites* are especially developed in these uppermost Silurian rocks, but they are all wonderfully rich in fossils. The total thickness of the Ludlow formation in England and Wales is estimated at not less than 2,000 feet.

The Ludlow formations are well represented in Bohemia, together with the other principal divisions of the Silurian series. They extend also to Scandinavia and Russia, but generally under a very different appearance, being identified only by the groups of fossils.

Lues (Lat.). As a Medical term, poison or pestilence; a plague.

Luff. The foremost or weather edge, or leech of a fore-and-aft sail. *To luff*, to bring the ship's head nearer the wind.

Luffer Boarding or Louvre Boarding. In Architecture, boards placed in an aperture above each other at regular intervals, and inclined to the horizon at an angle of 45°, so as to admit air to the interior without allowing the rain to penetrate.

Lug-sail. A four-sided sail bent to a yard, which is slung nearly horizontally, about one-third of its length from the windward end.

Lugger. A small vessel carrying two or three masts, with a lug-sail on each; it is capable of beating very closely up to the wind.

Lumachella. Shell marble; the fragments having a pearly lustre, it is sometimes termed *fire marble*. The finest specimens are from the lead mines of Bieiberg, in Carinthia.

Lumbago. Rheumatism.

Lumbar Abscess (Lat. *lumbus*, the flank). An abscess of the loins formed upon the psoas muscle; it is frequently mistaken for nephritic or rheumatic disease, and, when it forms a swelling in the groin, for hernia.

Lumber. In a trading vessel, the name applied to small spars, &c., as handspikes, anchor stocks, gaffs, &c.

LUNACY

Lumbrical Muscles (Lat. *lumbricus*, an earthworm). Small muscles of the hand which assist in bending the fingers.

Lumbricus (Lat.). A Linnæan genus of Vermes, now the type of a family (*Lumbricina*), which ranks as the first of the Setigerous Abranchian Anellidans in the system of Cuvier. All the species of this family—the *earthworms*, as they are commonly called—are characterised by a long cylindrical body, divided by rugæ into a great number of rings, and by an edentate mouth. The common earthworm (*Lumbricus terrestris*, Linn.) attains nearly a foot in length, and is composed of upwards of one hundred and twenty rings. This species is extremely abundant: they traverse the soil in every direction, swallowing quantities of earth, together with portions of roots and ligneous fibres, and other organised substances, which they assimilate for their own nutriment. Their castings constitute a rich soil.

In gardens and cultivated ground earthworms are rather beneficial than otherwise, by rendering the soil permeable to water, and mixing its constituents. It is only when they occur in lawns and gravel-walks that they become troublesome, and then only because their *casts* disfigure the surface. In such situations they may be removed or destroyed by the use of clear lime-water, made with quick-lime.

Luna. In Latin Mythology, the moon, worshipped along with Sol, the sun. She had a temple at Rome, on the Aventine. The name is a later form of Luc-na, and recurs in that of Lucina, the goddess who presided over childbirth, from the same root with lux, luceo, and Greek *Λεύκός*, white.

Luna Cornea. Fused chloride of silver; so called from its horn-like appearance, luna being the term by which the old chemists designated silver.

Lunacy. In Law, strictly, the condition of an insane person who has lucid intervals, which in former times were supposed to depend on the phases of the moon; whence such persons were styled *lunatici*. But, for convenience, the term is commonly used as embracing the condition of all those who are under certain legal disabilities on account of mental deficiency, such as idiots, fatuous persons, &c.; all, in short, who are of unsound mind. The chief of these disabilities are: incapacity to make contracts, either personal or affecting the estate; to sue or defend in courts of justice; to perform offices and duties; to make devises or bequests. By an ancient legal maxim, the sovereign has the custody of lunatics. This is in practice delegated to the keeper of the great seal, by virtue of the sign manual. His powers are now regulated by the Lunacy Act, 16 & 17 Vict. c. 70, and several amending statutes. Applications for a commission of lunacy are consequently directed to him. When he determines that such a commission is proper, it issues to certain commissioners, now styled masters, appointed by the same authority. But the Lord Chancellor has of late delegated this function

LUNAR BONE

to the Lords Justices. [CHANCELLOR.] By a recent enactment (25 & 26 Vict. c. 86), the enquiry by a jury into the state of mind of the party, formerly tried before one of the masters in lunacy, is now tried in one of the superior courts of law at Westminster. If the lunatic recover, the inquisition may be superseded. On the return of the inquisition, the custody of the lunatic's person and estate devolves on the crown; and the chancellor, on petition, appoints *committees* to have the custody of either or both. These may be any whom the chancellor thinks fit, although next of kin are ordinarily preferred. Lunatics are maintained by an allowance out of their own estate; when they have none, by statute, in public asylums. The custody of lunatics by private individuals is under the control of stat. 8 & 9 Vict. c. 100 and subsequent amending Acts, by which the powers vested in the Commissioners in Lunacy are placed on an entirely new footing, and efforts have been made to improve the management and condition of lunatics, which promise to be followed by the best results. Persons of unsound mind who are paupers, and those who have been tried for offences and found insane, and also lunatic convicts, are usually confined in county lunatic asylums, wherever these are established. As to the statistics of lunatic hospitals or asylums, see Degerando, *De la Bienfaisance Publique*, vol. iv. part iii. book iii.

The incapacity of a person of unsound mind to commit a crime depends, it is said, upon his irresponsibility, moral and legal. The general mode of directing a jury has been that they should acquit the prisoner, if satisfied that he had not a sufficient degree of reason to know that he was doing an act that was wrong, a test definitely laid down by the judges in Macnaughten's case in the year 1843, and always since adopted. On acquittal taking place on evidence of lunacy, the jury are now required, by 39 & 40 Geo. III. c. 94, to find specially whether the person was insane at the time of committing the offence; and on that finding he is taken into public custody. The law of lunacy in Scotland is regulated by the recent Act, 20 & 21 Vict. c. 71.

Lunar Bone. One of the bones of the wrist.

Lunar Caustic. Fused nitrate of silver.

Lunar Cycle. The period of time after which the new moons return on the same days of the year. [CYCLE.]

Lunar Distance. In Navigation, the distance of the moon from the sun, or from a fixed star or planet; by means of which the longitude of a ship is found.

Lunar Method. In Astronomy and Navigation, the method of determining the longitude of a place or ship from the observation of *lunar distances*. This problem, which is of the highest importance, on account of its being the handiest astronomical method of finding the longitude at sea, resolves itself into two

LUNAR MONTH

parts. The first is to ascertain the distance of the moon's centre from one of the principal planets or fixed stars, or the sun, at a given moment; and the second, to find the Greenwich time to which, according to the tables, that distance corresponds. The general method of procedure may be explained as follows: Six or eight observations of the star's distance from the nearest point of the moon's limb are taken with a sextant as quickly in succession as possible, and the corresponding time at each observation noted: the mean of the observed distances, at the mean time, gives a single distance corresponding to a known instant of time. The true mean time is here supposed to be given by the chronometer, the rate and error of which are determined by observations of altitude. Contemporaneously with the observations of distance, two assistants are sometimes employed in taking the altitudes both of the moon and star, for the purpose of applying the proper corrections for refraction, &c. The remainder of the operation consists in making the requisite calculations. In the first place, the moon's semidiameter is added to the observed distance, whereby the true apparent distance is found. In the next place, the corrections are applied for refraction and parallax, and the apparent distance reduced to the centre of the earth. This part of the operation is technically called *clearing the distance*. The computer then turns to the *Nautical Almanac*, in which the distances of the moon from the sun and some of the principal stars and planets are given for every three hours. Having found in the almanac the distances next less and greater than the true distance deduced from the observations, their difference gives the change of distance in three hours; whence, by interpolation, the Greenwich time is obtained at which the distance was exactly the same, and consequently the Greenwich time corresponding to the apparent time at the instant of the observation.

This method of finding the longitude at sea was first proposed by John Werner of Nuremberg so early as 1514, and recommended by several other astronomers who lived during the same century; but the theory of the lunar motions was then, and for a long time after, too imperfect to allow of its practical application; and before the invention of Hadley's quadrant, there was no instrument by which the distances could be measured with the requisite precision. The advancement of astronomy, and the perfection of instruments of observation, have obviated all difficulties; and the method of lunar distances is now mainly relied on by the mariners of all countries.

Lunar Month. The time in which the moon completes a revolution about the earth, and returns to the same position relatively to some celestial body, or point in space, with which her motion is compared. But the moon's period may be determined in relation to several objects—as the sun, the equinoctial points, a fixed star, the perigee or nodes of her orbit; and accordingly there are as many different lunar

LUNAR YEAR

months as there are assumed points of comparison, provided these points have different motions in the heavens.

1. The proper *lunar month* is the same as the *lunation* or *synodic month*, and is the time which elapses between two consecutive new or full moons, or in which the moon returns to the same position relatively to the earth and sun.

2. The *periodic month* or *synodic month* is the revolution with respect to the movable equinox.

3. The *sidereal month* is the interval between two successive conjunctions with the same fixed star.

4. The *anomalistic month* is the time in which the moon returns to the same point (for example, the perigee or apogee) of her movable elliptic orbit.

5. The *nodical month* is the time in which the moon accomplishes a revolution with respect to her nodes, the line of which is also movable.

The exact *mean* lengths of these different lunar months are as follow:

	d.	h.	m.	s.
Synodic month . . .	29	12	44	2.84
Tropical month . . .	27	7	43	4.71
Sidereal month . . .	27	7	43	11.54
Anomalistic month . .	27	13	18	37.40
Nodical month . . .	27	5	5	35.60

These *mean* motions are not uniform, but are subject to periodic and secular variations. [MOON.]

Lunar Year. The period of twelve synodic lunar months, containing consequently 354 days; the lunar months in the calendar being alternately 29 and 30 days. The exact period of 12 lunar months is 354 days 8 hours 48 min. 34 sec.; so that the lunar year of the calendar requires to be adjusted by intercalation every third year. [CALENDAR.]

Lunatic (Lat. *lunaticus*, from *luna*; Gr. *σεληνιακός*, from *σελήνη*, the moon, which was supposed to regulate their periods of insanity). [LUNACY.]

Lunation. The period of a synodic revolution of the moon, or the time from one new moon to the next one, in which time the moon passes through all her phases.

Lune (Lat. *luna*, the moon). This word formerly indicated the crescent-shaped plane figure, bounded by two circular arcs. Hippocrates of Chios accomplished the quadrature of such a figure. The term *lune*, however, is now used to denote that portion of the surface of a sphere which is enclosed between two great circles.

Lunette (Fr.). In Architecture, an aperture for the admission of light in a concave ceiling.

LUNETTE. In Fortification, a detached work consisting of two faces and two flanks. It is especially applicable to the defence of a fortress when its faces can be directed so that its glacis can receive flank defence from the fortress, or other detached works within moderate range. It is in general the best form of detached work. [FORTIFICATION.]

LUPINUS

Lungs (Ger. *lungen*). The viscera by which respiration is carried on. In the human subject the right lung is divided into three lobes, the left into two. They are, as it were, suspended in the chest by the *trachea*, and separated by the *mediastinum*; they are also attached to the heart by the pulmonary vessels. They are nourished by the bronchial artery, which is a branch of the aorta; and the pulmonary artery carries the venous blood through them from the heart, to subject it to the action of the air in their cellular structure: the blood when arterialised returns to the heart by the pulmonary veins, the four trunks of which enter the left auricle. The bronchial veins terminate in the *vena azygos*. The nerves of the lungs are from the eighth pair and great intercostal.

Lungwort. In Botany, the common name for *Sticta pulmonacea*, a lichen which grows extensively on the trunks of trees, and is occasionally used in medicine. In Siberia it is said to be employed as a substitute for hops. The same name is also applied to the genus *Pulmonaria*.

Lunisolar (Lat. *luna*, the moon, and *sol*, the sun). Combining the motions of the sun and moon. A lunisolar period is that after which the eclipses again return in the same order. [CYCLE.] The Dionysian period of 532 years, formed by multiplying together the solar and lunar cycles of 28 and 19 years, has sometimes been called the lunisolar year.

Lunnite. A variety of Phosphorcalcite or hydrated phosphate of copper, occurring in radiating fibrous masses of a beautiful emerald-green colour.

Lupercalia. A Roman festival in honour of Lupercus, an agricultural god, who was invoked for the fertility of the land and as a protector against wolves. Livy held it to be the same with an Arcadian festival of the god Pan, and to have been introduced at Rome by Romulus. (Lewis's *Credibility of Early Roman History* ch. viii. sect. iv.) The festival recurred yearly in February, and was of a peculiarly rude character. The priests ran naked, and with thongs of goat-skin touched the crowd, and especially women, a practice arising originally from the habit of touching the flocks to insure their increase.

Lupercal. The Roman priests of Lupercus. There were three companies of them; viz. the Fabiani, Quinctiliani, and Julii—the last of whom were founded in honour of Julius Cæsar. [LUPECALIA.]

Lupia (Gr. *λυπίω*, I molest). An encysted tumour.

Lupinite. A bitter substance, extracted from the leaves of the white lupin.

Lupinus (Lat.). A very ornamental genus of papilionaceous *Leguminosæ*, of which many beautiful species, annual or perennial, are met with in gardens. One species, *L. albus*, which has been long cultivated, is extensively sown in the south of Europe, for forage, for ploughing in to enrich the land, and for the seeds, which form a great article of food in

LUPULIN

some districts, their bitterness being removed by boiling.

Lupulin. The active principle of the hop. [Hors.]

Lupus (Lat.). The Wolf. One of the southern constellations, situated on the south of Scorpio.

Lupus. In Pathology, a disease which eats away the parts attacked by it with great rapidity.

Lurcher. A variety of dog, of mongrel descent, probably allied both to the shepherd's dog and to the greyhound. It is usually employed by poachers.

Luscinia. [NIGHTINGALE.]

Lusiad. The name given to the great epic poem of Portugal, written by Camoens, and published in 1671. The subject of this poem is the establishment of the Portuguese empire in India. Among all the heroic poets, says Schlegel, either of ancient or modern times, there has never, since the Homeric age, been any one so loved or honoured by his countrymen as Camoens. It seems as if the national feelings of the Portuguese had centred and reposed themselves in the person of this poet, whom they consider as worthy to supply the place of a whole host of poets, and as being in himself a complete literature to his country. Few modern poems have been so frequently translated as the *Lusiad*. Mr. Adamson (*Memoirs of the Life and Writings of Camoens*) notices one Hebrew translation of it, five Latin, six Spanish, four Italian, three French, four German, and two English. Of the two English versions, one is that of Sir R. Fanshawe, written during Cromwell's usurpation, and distinguished for its fidelity to the original; the other is that of Mickle, who, unlike the former, took great liberties with the original, but whose additions and alterations have met with great approbation from all critics—except, as indeed was to be expected, from the Portuguese themselves. (*Quarterly Review*, vol. xxvii.)

Lustratio (Lat. *lustratio*). A purification by washing or sprinkling with water. Among the Greeks it followed the commission of some crime, which it was to expiate. With the Romans it was simply an act to win the favour of the gods; as on fields after the crops were sown, and on armies before beginning a campaign. A general lustration of the Roman people, called also *lustrum* (from *luo*, the Greek *λούω*, *I wash*) was held by the censors, at the end of every period of five years, when a sacrifice was offered up, called *Suovetaurilia* (i. e. the offering of a pig, sheep, and ox). Hence the word *lustrum*, as signifying the time between two such lustra or days of purification, came to be used for the exact space of five years.

Lustrum. [LUSTRATION.]

Lusus Naturæ (Lat. *a sport of nature*). A term applied to anything unnatural in the physical world.

Lute (Ital. *luto*, derived by Mr. Wedgwood from the Arabic *al ud*). A musical stringed

LUTHERANS

instrument of the guitar species, and played in a similar way; but in form more resembling the section of a pear, with a back in ribs, like those of a melon.

Lute Composition (from Lat. *lutum*, *moist earth*). A mixture applied to the bungs of powder-cases to keep them air-tight. It consists of fourteen parts of tallow, and six of beeswax, melted together. When cold, it becomes hard, and must be beaten till soft before use.

Clay forms the basis of many lutes; and among other substances employed in lutes may be mentioned borax, moistened bladder, linseed meal, and caoutchouc.

Luteoline and **Luteoleine.** Peculiar colouring principles, obtained from *weld*.

Lutes (Lat. *lutum*, *moist earth*). Under this term, a variety of compounds are used for securing the junctures of vessels, or protecting them from the action of heat. Slips of wetted bladder; linseed meal made into a paste with gum-water; white of egg and quicklime; glazier's putty, which consists of chalk and linseed oil; and *fat lute*, composed of pipeclay and drying-oil, are useful for retaining vapours; but to withstand the action of a high temperature earthy compounds are required. Loam, or a mixture of clay and sand well beaten into a paste and then thinned with water, and applied by a brush in successive layers to retorts, tubes, &c., enables them to bear a high temperature; if a thick coating is required, care should be taken that the cracks are filled up as the lute dries; a little tow mixed with it renders it more permanent. If the lute is intended to vitrify, as, for instance, to prevent the porosity of earthenware at high temperatures, a portion of borax, or of red lead, may be mixed with it.

Lutherans. The denomination of Christians whose religious system had its origin in the preaching of Luther. This system in some respects approaches nearer to Romanism than that of any other of the reformed churches. The notions of Luther upon the nature of the Eucharist are known under the name of *consubstantiation*, or the coexistence of the body and bread, the blood and the wine, at the same time. It encourages also the private confession of sins, makes use of wafers in the administration of the Lord's Supper, and allows of images in churches. It insists, however, very strongly upon Luther's cardinal doctrine, the justification of man by faith, and not by any merit in human actions. With respect to the divine decrees, it holds that God foreknows the dispositions of men, whether they will be good or bad, and predetermines their salvation or rejection accordingly; differing therein from the tenet of the Calvinists, which represents the Supreme Being as making His decrees by His own mere will. The dogmas of the Lutheran church are carefully set forth in various symbolic books: the *Confession of Augsburg*, the *Articles of Smalcald*, the *Shorter and Larger Catechisms* of Luther, and the

LUTRA

Form of Concord. The principle, however, of this church, which considers Christians as accountable to God alone for their religious opinions, allows its teachers, at the present day, an unbounded liberty of dissenting from these decisions. The Lutheran church predominates in the north of Germany, in Prussia, Norway, Denmark, and Sweden: there are congregations also of the same denomination in England, Holland, Russia, and America. In the Prussian dominions it has been remodelled in modern times, and is called the Evangelical Church. [CHRISTIANITY.]

Lutra (Lat. *an otter*). A genus dismembered by Storr from the Linnæan *Mustela*, and now raised to the rank of a family (*Lutridæ*).

Luxation (Lat. *luxare, to put out of joint*). A dislocation of a bone.

Lux. The name of a bone in the human body, celebrated in Rabbinical writings, and supposed to be indestructible; according to some, it was a vertebra; according to others, it was the sesamoid bone of the great toe, or one of the triangular bones near the lambdoidal suture of the cranium. It is also regarded as the *os sacrum* or penultimate segment of the skeleton of man.

Lycanthropy (Gr. *λυκανθρωπία*, from *λύκος*, a wolf, and *ἄνθρωπος*, a man). Herodotus relates that the Neurians, a Scythian tribe, were supposed to be changed, for a certain number of days every year, into wolves, and then to resume their former shape; and a similar superstition is noticed by Virgil in his *Eclogues*, by Pliny, Pausanias, and other writers. The same superstition, of the power possessed by men of converting themselves into wolves, remained in more modern times; but that which the classical ancients believed to be effected by the power of herbs, or by innate powers, was by Christians considered as a species of sorcery. These human wolves were called *loup-garoux* by the French, *were-wolves* by the Anglo-Saxons, *wchruölfe* by the Germans: words of the same derivation, showing that the superstition in those countries was of Teutonic origin. They were believed to be extremely ferocious, and to devour not only beasts, but human beings; but if they were pursued and wounded, the spell was frequently dissolved, and the sorcerers were found mutilated in those limbs in which they had received the wound in their wolfish shape. From the prevalence of these superstitions in the minds of an ignorant peasantry originated the hideous species of madness termed *lycanthropy*, in which the patient believed himself to be a wolf, and frequently imitated the actions and howl of that animal. In France, in the sixteenth century, numbers of these unfortunate beings were executed, like witches, on their own confession. Some of these maniacs declared that they were actually wolves, but that their hair grew inside, or between the skin and the flesh. Orribasius, who lived in the fifth century of our era, mentions

LYCOPERSICUM

lycanthropy as a species of madness, and describes its symptoms and the cure. This species of insanity seems to have gradually died away along with the superstition which gave it birth. (Lecky, *History of Rationalism*, ch. i.)

Lycæon (Gr. *Λυκαίων*). In Greek Mythology, a son of Pelægus, who is said to have first civilised Arcadia, and to have built the town of Lycosura. The number of his sons is given as twenty-two or fifty; their impiety led Zeus to visit them in the guise of an old man, and when they placed before him a meal of human flesh, they were by him, according to Pausanias, changed into wolves; but Apollodorus (iii. 8. 1) merely says that they with their father were killed by a thunderbolt. This legend is simply an attempt to account for a name the true meaning of which had been forgotten. Thus the name of Arcas, the eponym of Arcadia, belongs to the same root with Arctos, Arcturus, a constellation, of which the Sanscrit name *Rikshi*, *wise-men*, was a corruption of *Riksha*, a *shiner*. Callisto, the daughter of Arcas, is likewise said to have been turned into a wolf by the wrath of Hera. The mistake arose by the confusion of the Greek word *λύκος*, a wolf, with *λευκός*, *λυκίος*, &c., words signifying *light*, and akin to the Latin *lux*, *lucro*, *lucina*, *luna*, &c.

Lycæum (Fr. *Lycée*). In France, establishments for secondary instruction, created by the state, were so termed at the time of the Revolution and down to 1814, when the name *collège* was substituted. Since 1848, the name has been revived. In 1858 there were seventy lycæums. The payment to be made by the children is fixed by laws made in 1853 and 1857, and varies according to the classes or *divisions*, of which there are three: elementary, of grammar, superior. A *pensionnaire* in a lycæum at Paris pays 950, 1,050, 1,150 francs per annum in these three classes respectively. There are also *demi-pensionnaires*, and *externes* or day-boarders.

Lychnites. An ancient name of marble, from Gr. *λύχνος*, its quarries being worked by lamp-light.

Lycium (from Lycia in Asia Minor, its native country). A genus of *Solanaceæ*, one of which, *L. barbarum*, a scandent plant frequently seen on walls and cottages, is often called the Tea-plant, its leaves being recommended as a substitute for tea.

Lycopodon (Gr. *λύκος*, and *πόδος*). A genus of Fungi, to which the name Puff ball is given, from their globular form, and from the fact that when they are ripe a blow causes the spores to fly out like a puff of smoke. They are abundant in many places. *L. Bovista*, when young, if cut into slices and fried, is one of our best cooking funguses. The dry mass of threads and spores in the mature plant may be used as a styptic; and the fumes are used for stupefying bees.

Lycopersicum (Gr. *λυκοπερσικόν*). The Solanaceous genus which yields the Tomato, distinguished from *Solanum*, with which it was

LYCOPODIACEÆ

ormerly united, by the anthers being connected with a thin membrane prolonged upwards, and by their cells opening by a long slit instead of by two pores at the top. The Tomato or Love Apple, *L. esculentum*, is an annual plant, native of South America, and long introduced into most warm or temperate countries, where it is cultivated for the sake of its wholesome fruit, which, either green or ripe, is eaten in various ways.

Lycopodiaceæ (Lycopodium, one of the genera). A natural order of Acrogens, inhabiting all parts of the world, but abounding chiefly in hot humid situations. They are intermediate, as it were, between Ferns and *Conifera* on the one hand, and Ferns and Mosses upon the other. *Lycopodium rubrum* is a violent cathartic; *L. clavatum* and *Selago* excite vomiting; and the powder contained in the seed-vessels of all the species is so highly inflammable as to be employed occasionally in the manufacture of fireworks. They are propagated by spores formed in two-valved cases axillary to the upper leaves.

Lycopodium. A fine yellow dust or powder, being the seed of the *Lycopodium clavatum*, or Club Moss: when thrown into the flame of a candle, or of spirit of wine, it burns with a bright flash. It is used for producing theatrical lightning, and is an excellent substance to sprinkle upon pills to prevent their adhering.

Lycosa (Gr. *λύκος*). A genus of spiders, in which the eyes form a quadrilateral group, as long as or longer than it is wide; the two posterior eyes not placed on an elevation. The first pair of legs is evidently longer than the second, but shorter than the fourth, which is the shortest of all. The internal extremity of the jaws is obliquely truncated. Almost all the *Lycosa* keep on the ground, where they run with great swiftness. They inhabit holes in the ground, which they line with silk, and enlarge in proportion to their growth. Some establish their domicile in chinks and cavities in walls, where they form a silken tube, covered externally with particles of earth or sand. In these retreats they change their tegument; and, as it appears, after closing the opening, pass the winter in a state of torpidity. The females, when they go abroad, carry with them their eggs enveloped in a cocoon attached to the abdomen by threads. On issuing from the egg, the young ones cling to the body of the mother, and remain there until they are able to provide for themselves. The *Lycosa* are extremely voracious, and courageously defend their dwelling. The famous Tarantula spider is a species of this genus.

Lydian Stone. A silicious slate or flinty Jasper of a velvet-black colour, used as a touchstone for testing the quality of gold and silver.

Lyncephala (Gr. *λύω*, I loose, and *ἐγκέφαλος*, brain). In this, the lowest subclass of the class Mammalia, the name is given from the comparatively loose or disconnected state of the cerebral hemispheres. The size of these hemispheres is such that they leave exposed the ol-

LYRE BIRD

factory ganglions, the cerebellum, and more or less of the optic lobes; their surface is generally smooth; the anfractuosities, when present, are few and simple.

Lying Panels. In Architecture, the panels in which the fibres of the wood lie in a horizontal direction.

Lying-to. A Nautical term, denoting the state of a ship when the sails are so disposed as to counteract each other, and thereby retard or destroy the progressive motion of the vessel. The fore and main staysails and mizen trysail serve very well for this purpose, as they cause but little way, and have sufficient power to keep the ship heeled over, and therefore steady, with her decks turned from the sea. When the sea runs very high, the lower sails are liable to be becalmed by the waves, and therefore to suffer the ship to roll to windward; the main-topsail is then used.

Lymph (Lat. *lympa*, water). The liquid contained in the lymphatics.

Lymphatics (Lat. *lymphaticus*). Absorbent vessels, which carry lymph from all parts of the body, and terminate in the thoracic duct.

Lynch Law. The irregular and revengeful species of justice administered by the populace in some parts of the United States is said to have been so called from a Virginian farmer of the name of Lynch, who took the law into his hands on some occasion, by chasing a thief, tying him to a tree, and flogging him with his own hands.

Lynx (Gr. *λύξ*). A name given to the different species of a group of the *Cats* (*Felidae*), distinguished by short tails, and generally tufted ears. The lynxes have been long famed for their sharp sight.

LYNX. A constellation of the northern hemisphere, formed by Hevelius.

Lynx Sapphire or **Luchs Sapphire.** A name given by jewellers to dark greyish or greenish-blue varieties of Sapphire and Iolite.

Lyra (Lat.). A portion of the brain, the under surface of the back of the corpus callosum, the medullary fibres of which are so arranged as to give it somewhat of the appearance of a lyre.

LYRA. The Lyre: one of the forty-eight constellations of Ptolemy. It is situated in the northern hemisphere.

Lyre (Gr. *λύρα*, Lat. *lyra*). A musical instrument, of the greatest antiquity, among the Egyptians and Greeks. The Greeks attribute the invention to HERMES [which see]. It is generally considered that the original Egyptian lyre was only of three strings. At a later period the lyre consisted of eleven strings, which were made of the sinews of animals; its body was hollow to increase the volume of tone; and it was played with the *plectrum* or lyre-stick of ivory or polished wood, and sometimes with the fingers like the harp. It went by the different names of *lyra*, *phorminx*, *barbitos*, and *cithara*.

Lyre Bird or **Lyre Pheasant.** [*MENURA*.]

LYRIC

Lyric. [Oda.]

Lythraceæ (Lythrum, one of the genera). A natural order of polypetalous Exogenous plants of the Saxifragal alliance. They have long tubular striated calyces, in the orifice of which are inserted the petals, while the stamens grow nearly at the base. They are little known

MACEDONIANS

in cultivation; but some of them, belonging to the genera *Lagerströmia*, *Diplusodon*, *Lafœnsia*, &c., are objects of striking beauty. The Tulipwood of the cabinetmaker is the trunk of *Physocalymna floribunda*, and the Henna, employed in the toilet of Oriental ladies, is obtained from *Lawsonia inermis*.

M

ME. The labial letter of the liquid series. It is susceptible of various interchanges, more especially in the Greek and Latin languages. In writing two M's successively, the Germans frequently drop one, and replace it by a stroke over that which they retain; thus, *m*. As an abbreviation, M stands for Marcus, Manlius, Martius, and Mucius; M.A. for Magister Artium, MS. for Manuscript, and MSS. for Manuscripts. M, or, more properly, a symbol somewhat resembling it, was used by the Romans to denote 1,000; and the moderns have also adopted that letter.

M. In Medical prescriptions, M stands for *misce*, or mix; also for *manipulus*, a handful.

MEAB. The name given by the English poets of the fifteenth and succeeding centuries to the imaginary queen of the fairies. The passage in *Romeo and Juliet*, in which her qualities and attributes are set forth, is familiar to all.

MAC. A Scotch term, signifying *son*, prefixed to many surnames, as *Mac Donald*, &c. It is synonymous with *Fits* in England, and *O* in Ireland.

MACACUS. A genus of Catarrhine or Old World monkeys, characterised by having a fifth tubercle on their last molars; ischial callosities and cheek pouches; comparatively short and thick limbs; a projecting muzzle and prominent superciliary arches. They have generally a pendent tail; but in some it is short, as in the pig-tailed baboon (*Macacus Rhesus*). When they cry out, they inflate a membranous sac, which communicates with the larynx above the thyroid cartilage.

MACADAMISING. A method of making roads, introduced by Sir J. Macadam, which consists in placing stones, broken into fragments, on a convex surface. The road ought to be completed by passing a very heavy roller over it, and this is enforced in Paris; but in London the work of smoothing down the broken stones is left to be completed by the carts and carriages which pass over it, greatly to their detriment, and to the profit of the contractor.

MACARONI. [VERMICELLI.]

MACARONIC VERSE. Verse in which the words of a modern language are ludicrously distorted into Greek or Latin inflections and metre. Theophilo Folengo, who wrote under the name of Merlinus Coccaius, in Italy, in the sixteenth

century, and calls himself the inventor of this sort of burlesque composition, informs us that its name is derived from the Italian macaroni, eatables composed of flour, cheese, and butter; and that it expresses the gross and rustic characters appropriate to its words and sentiments. Drummond's *Polemio-Middinia*, a Scottish burlesque, is perhaps the best known macaronic form of our language. See the learned work of Mr. Delepierre on *Macaroniana*.

MACAW. A term applied to those parrots (*Macrocercus*) which are distinguished by the greater length of tail, and by the greater brilliancy of their colours.

MACCABEES, Books of the. The last two books in the arrangement of the Apocryphal writings enumerated in the sixth article of the church of England. The first is a Greek translation (as is supposed) from a Chaldaic original. The second appears to be a compilation from various sources. The two books are not connected; the former comprehends the events of Jewish history for nearly 40 years, a.c. 176 to 139; the second begins about a.c. 187, and extends over about 16 years. Neither has ever been reckoned by the Jews in their catalogue of sacred writings; but they are received into the canon of Scripture by the church of Rome, with the title of *3rd and 4th Chronicles*. There are two other books, commonly called *3rd and 4th Maccabees*, which were never received by any church.

MAÇE (Ital. *mazza*, a club; Fr. *masse*; Lat. *massa*; Gr. *μάζα*). A club of metal used as a military weapon from the most remote times. About the period of Edward II. maces were generally used in England, both in battles and tournaments; and they remained in use till the time of Elizabeth, when they appear to have been displaced by the pistol. Maces are still used by the Turkish cavalry. The mace, as an ensign of authority, is often borne before magistrates. By the old English writers it is used synonymously with sceptre. It was invariably the distinguishing weapon of a sergeant-at-arms.

MAÇE, the external envelope of the seed of the nutmeg, is a particular form of what botanists call *arillus*. It is an agreeable aromatic, and is chiefly used in cookery or in pickles.

MACEDONIANS. In Ecclesiastical History, a sect which derives its name from a bishop

MACER

of Constantinople, who, in the fourth century, denied the distinct existence and Godhead of the Holy Spirit, which he conceived to be merely 'a divine energy diffused throughout the universe,' 'while the Father and Son together constitute the one existing Deity.' These opinions were condemned at the second general council held at Constantinople in 381. [ΠΡΕΒΥΜΑΤΟΜΑΧΗ.]

Macer. The bark of the root of a tree growing in Malabar. It is astringent, and celebrated for the cure of diarrhoea.

Maceration (Lat. *maceratio*, a *soaking*). The steeping of substances in a cold liquor.

Machairodus (Gr. *μάχαιρα*, a *sabre*, and *ὄδον*, a *tooth*). An extinct mammal, allied to the existing Felids, in which the upper canines were much elongated, trenchant, sharp-pointed, and sabre-shaped. Species varying from the size of a lion to that of a leopard have been found in miocene, pliocene, and cave deposits in Auvergne, Eppelsheim, Val d'Arno, Devonshire, the Pampas, Brazilian bone caves, and the Sewalik tertiaries of India.

Machetes (Gr. *μάχητος*, a *combatant*). The generic name under which Cuvier has distinguished the ruffs and Reeves from the sandpipers, godwits, and other allied Gallinæ. The ruffs have the bill and carriage of the genus *Calidris*; but the membrane between their external toes is nearly as extensive as in *Limos*a. Our native species (*Machetes pugnax*, Cuv.) is somewhat smaller than a snipe, and celebrated for the furious combats that take place among the males in their nuptial season. At this period the head is partly covered with red papillæ; the neck is surrounded with a thick collar of feathers, which often varies in different individuals.

Machiavelism. A name given to the system of governing propounded in the general writings of Machiavelli, and particularly in his treatise called *The Prince*. The term is still used in a disparaging sense, notwithstanding the different construction which has of late been given to the motives and purposes for which Machiavelli wrote his work.

Machicolis (Fr.). A system of holes between the corbels supporting a gallery or balcony projecting from the top of a wall or tower, through which missiles can be thrown upon the heads of an enemy below. A building thus fortified is said to be *machicolated*.

Machine (Gr. *μηχανή*). In a general sense, this word signifies anything which serves to increase or regulate the effect of a given force. Machines are either *simple* or *compound*. The simple machines, otherwise called the *simple mechanical powers*, are usually reckoned six in number; namely, the **LEVER**, the **WHEEL AND AXLE**, the **PULLEY**, the **WEDGE**, the **SCREW**, and the **FUNICULAR MACHINE** [see the respective terms].

Compound machines are formed by combining two or more simple machines. They are classed under different denominations, according to the forces by which they are put in motion, as

MACHINE

hydraulic machines, *pneumatic machines*, *electrical machines*, &c.; or the purposes which they are intended to serve, as *military machines*, *architectural machines*, &c.

Although there are no limits to the combinations and adaptations of machinery, there are certain general principles which may be applied in estimating the effects of any machine whatever. When a machine attains its state of uniform motion, the momentum of the power is equal to that of the resistance, and is the same that would be in equilibrio with the resistance if there were no motion at all. From this principle, and from the consideration that in all machines the work done is to be estimated not merely from the quantity of resistance which is overcome, but from the quantity overcome in a given time, we can ascertain the relation that ought to subsist between the velocity and the load or resistance in order that the effect of the machine may be a maximum. This maximum effect is produced when the two following conditions are fulfilled: 1. When the load, or resistance, is about four-ninths of that which the power, when fully exerted, is just able to balance, or that which would keep the machine at rest altogether; and, 2. When the velocity of that part of the machine to which the power is applied is one-third of the greatest velocity of the power. These conditions are deduced from the following empirical expression, which is adopted by Euler and other writers to represent the law of the moving power. Let P = the power applied (or weight which the power, when fully exerted, is just able to overcome); R = the resistance, or load, or weight to be overcome; c the greatest velocity, or that at which the power ceases to act; v = any other velocity: then the law of the moving power is

$$R = P \left(1 - \frac{v}{c}\right)^2$$

The variables in this expression are R and v , and the effect is represented by the product Rv ; on making which a maximum, the rules of the differential calculus give $v = \frac{1}{3}c$; whence the

formula becomes $R = \frac{4}{9}P$.

From these expressions it follows, that when the moving power and the resistance are both given, if a machine be so constructed that the velocity of the part to which the power is applied is to the velocity of the part to which the resistance is applied in the ratio of 9 R to 4 P , the effect of the machine will be a maximum; in other words, it will work to the greatest possible advantage. The above conditions apply equally to machines impelled by animal force and the agents of nature, as running water, steam, the force of gravity, &c. An animal exerts itself to the greatest advantage, or performs the greatest quantity of work in the least time, when it moves with about one-third of the utmost speed with which it is capable of moving, and is loaded with four-ninths of the greatest load which it is

E E

MACHINE

capable of putting in motion. It has been supposed in the above remarks that the friction of the parts of the machine is included in the resistance. (Coriolis, *De l'Effet des Machines*; Navier, *Leçons sur l'Application de la Mécanique*; Belidor, *Architecture Hydraulique*; Gregory's *Mechanics*; Moseley's *Mechanics applied to the Arts*; &c.)

Machine, Calculating. [CALCULATING MACHINE.]

Machine, Printing. [PRINTING.]

Macigno (Ital.). A hard silicious sandstone.

Macquerel. A well-known European and American fish, of which the body is spindle-shaped, smooth, beautifully coloured, and with small scales. It is distinguishable for the rapidity with which it dies out of the water, and for the facility with which it becomes tainted. [SCOMBER.]

MacLaurin's Theorem. In Mathematics, a theorem by which, whenever possible, a function may be developed in a series proceeding according to ascending powers of the independent variable. It is a particular case of TAYLOR'S THEOREM, and was given by MacLaurin in his *Treatise on Fluxions*, Edinburgh 1742, though it had been previously noticed by Stirling. It may be thus expressed:

$$F(x) = F(0) + F'(0)\frac{x}{1} + F''(0)\frac{x^2}{1.2} + \dots$$

$$F^{(i)}(0)\frac{1}{1.2 \dots i} + R_i,$$

where $F^{(i)}(x)$ is the i^{th} derived function of $F(x)$, and $F^{(i)}(0)$ its value when $x=0$. The remainder R_i , which it is necessary to consider in all cases, has the value

$$R_i = F^{(i+1)}(\theta x) \frac{x^{i+1}}{1.2 \dots (i+1)},$$

where θ is some proper fraction. The equivalent form, as given by Cauchy, would be

$$R_i = F^{(i+1)}(\theta_1 x) \frac{(1-\theta_1)x^{i+1}}{1.2 \dots i},$$

or, expressed as a definite integral,

$$R_i = \frac{1}{1.2 \dots i} \int_0^x x^i F^{(i+1)}(x-s) ds.$$

The series breaks off at the $(n+1)^{\text{th}}$ term when $F(x)$ is a rational integral function of the n^{th} degree, and to be valid the theorem requires that neither $F(x)$ nor any of its derivatives shall become infinite for the values of x under consideration.

Maclo. A mineral; called also CHIASTOLITE [which see]. It forms prismatic crystals, white externally and grey within, which are found embedded in clay-slate. Its principal component parts are silica and alumina, with a little oxide of iron.

Macles or Twin Crystals. [CRYSTALLOGRAPHY.]

Macurette. A mineral from New York and New Jersey, named after Dr. MacLure. It occurs in roundish embedded masses, imper-

fectly crystalline. It is a silicate of magnesia, with traces of potash, oxide of iron, and fluorine.

Macmillanites. A religious sect in Scotland, the successors and representatives of the Covenanters in the seventeenth century. On the first settlement of presbytery as the established church of Scotland at the Revolution in 1688, a small body of the people condemned the principles on which that act was founded as Erastian. They insisted that the church, though endowed by the state, should be entirely independent of civil authority, and uncontrollable and supreme in itself. Though reduced to a very small number, they maintained their principles with unshaken firmness, and would accept of no conditions of which these were not the basis. They also continued zealously to maintain those praying societies (hence they were sometimes called *Society people*) which they had formed in the time of Charles II. They remained without a pastor for sixteen years. Meanwhile, John M'Millan, who had been ordained parochial minister of Balmaghie, in the stewartry of Kirkcudbright, in 1701 adopted and publicly avowed their principles; and was, in consequence, deposed in 1704. He did not, however, renounce his ministerial character; but continued to officiate both among his former people, who almost to a man adhered to him, and others who favoured his views. In 1706, having received a unanimous call from the scattered societies to be their minister, he accepted the invitation; and in a short time he was joined by John M'Neil, a licentiate of the established church. The veneration which M'Millan and M'Neil entertained for presbyterian government, prevented any attempt being made to obtain ordination for the latter in an irregular way. Neither would they compromise their principles to gain the co-operation of other ministers who, for somewhat different opinions, had been expelled from the establishment. They renewed the Covenant in 1712, and never ceased to bear public testimony against what they regarded the defections and corruptions of the church of Scotland. On the death of M'Neil, which took place not long afterwards, M'Millan was joined by the Rev. Thomas Nairn. The prospects of the *M'Millanites*, as this sect had long been called in honour of their leader, now began to brighten. Their two clergymen and some lay elders (formerly ordained) constituted a presbytery, in 1743, at Braehead, near Carnwarth, Lanarkshire, and gave their body the name of the Reformed Presbytery—a designation which has superseded, in a great measure, that of M'Millanites. They are also called *Mountain or Hill people*; because, having at first no chapels, they conducted public worship, in imitation of their persecuted ancestors, in the open air, generally on the side of a hill. (Adams's *Religious World Displayed*, vol. iii. 157-169; *The Testimony of the Reformed Presbyterian Church, Paisley 1837: Historical Part of the Testimony, Glasgow*

MACQUER'S SALT

1839; *A Short Account of the Old Presbyterian Dissenters*, Glasgow 1824; *Acts of Gen. Assem. apud Ann.* 1704, 1708, 1715.) [CAMBONIANS; COVENANTERS.]

Macquer's Salt. A Pharmaceutical designation of the binarsenate of potassa.

Macrauchenia (Gr. *μακράχην*, *long-necked*). A genus of colossal Perissodactyle (three-toed) Mammalia, which exhibits the character peculiar to the existing Camels and Llamas, of having the cervical vertebra not perforated by the usual arterial foramina. Its fossil remains have been found in Patagonia and Bolivia.

Macrocosm (Gr. *μακρός*, *large*; *κόσμος*, *world*). A term applied to the world at large, or *universe*, as opposed to *microcosm*, having reference to man.

Macroductyl (Gr. *μακροδάκτυλος*, *long-fingered*). A tribe of wading birds, comprehending those in which the toes are remarkable for their extreme length; as the *Jacanas*.

Macromyelon (Gr. *μακρός*, and *μυελός*, *marrow*). A term for the MEDULLA OBLONGATA [which see].

Macropiper (Gr. *μακρός*, *long*, and Lat. *piper*). The Ava or Kava root of the Polynesian is furnished by a species of this genus, *M. methysticum*, a shrubby plant, with knotty stems, cordate leaves, and axillary spikes of flowers. The leaf has narcotic properties, and is employed medicinally; but its most important use is to supply the narcotic stimulant beverage called *kava*, of which the natives partake before they engage in any important business, or any religious rites. The Kava is prepared by chewing the root of the plant, and thus extracting the juice, which is afterwards collected.

Macropus (Gr. *μακρόπους*, *long-footed*). The generic name of the kangaroo; also applied to a genus of beetles.

Macrotherium (Gr. *μακρός*, and *θηρion*, *a beast*). A genus of Bruta, which was originally founded on a single ungual phalanx, discovered in the miocene deposits at Eppelsheim. The conclusions of Cuvier, drawn from an examination of this toe-bone, were, that it belonged to an animal allied to the existing Pangolin (*Manis*), and this induction has been verified by the discovery of similar bones, in deposits of the same age at Sansan, in the South of France. The discovery of two molar teeth, the humerus, ulna, and femur, leads to the conclusion that it also offered much analogy to the existing *Orycteropus*.

Macrourans (Gr. *μακρός*, and *οὐρά*, *a tail*). A section of Decapod Crustaceans, including all those which have the tail, or post abdomen, as long or longer than the body.

Mastra. A Lamarckian genus of bivalve shells, in which the ligament is attended on both sides with a lateral tooth which locks within two laminae of the opposite valve.

Maculae (Lat. *spots*). Dark spots on the surfaces of the sun and moon, and on some of the planets. The solar spots are very variable

MADREPORA

as to form and continuance. They were first observed by Galileo in Italy, and Harriot in England. [MOON; SUN.]

Madame, Mademoiselle (Lat. *mea domina, my mistress*). The titles given by French etiquette to married and unmarried ladies respectively. The latter, in the strict usage of the old régime, belonged more especially to the eldest daughter of a brother or uncle of the reigning king. Thus the daughter of Gaston of Orleans is described as 'Mademoiselle,' in the writings of the period of the Fronde. For the history of the word, see Max Müller, *Lectures on Language*, first series, vi.

Madarosis (Gr. *μαζαρός*, *melting away*). A falling off of hair, especially of the eyelashes.

Madder, Colouring Matters of. **Madder**, *Rubia tinctorum*, grows naturally in the south of Europe, and is largely cultivated in Holland. Its tinctorial power exists in the woody portion of its roots. This fibrous matter is met with in commerce under the name of *lisari*, or *alizari*, or, if ground, under that of *garanor*. It is an article of large consumption with dyers and calico printers, and is used in the production of all shades of red, purple, brown, and even black. *Rubian* is, according to Schunck, the chief colour-producing agent in madder-root. It is itself almost colourless, but by action of air under the influence of a ferment, *erythrozym*, contained in the root, it splits up into *alizarin*, the true madder colour, and grape sugar: these are accompanied by secondary yet definite crystalline compounds, namely, *rubicetin*, *verantin*, *rubifin*, and *rubigin*. Under the influence of acids it yields most of the above compounds, and in addition *rubianin*, and by alkalies *rubiadin*. *Purpurin* accompanies, and is possibly only a variety of *alizarin*. *Rubiadin* is a yellow colouring matter, and *chlorogenin* a green pigment contained in madder. Madder colours are persistent under the influence of air and light, and are easily fixed by mordants. [RUBIACEÆ.]

Madia (Gr. *μαδός*, *bald*). A genus of Composite plants, of which the only species, *M. sativa*, a native of Chili and North California, is there cultivated for the oil extracted from its fruits.

Madonna (Ital. *my lady*, for Lat. *mea domina*). An Italian term applied to the Virgin Mary. Hence pictures of the Italian school representing the Virgin are generally designated as *Madonnas*. [MADAMÆ.]

Madrepore (Fr. *madrepore*). The word appears to have been first used by Imperati to designate a genus of Lithophytes, in which the calcareous axis has its whole surface beset with small lamellate and stellate depressions.

The genus was adopted by Linnæus, who placed it among his *Vernæ Zoophyta*, and characterised it as follows: 'Animal resembling a medusa; coral with lamellate star-shaped cavities.' It is scarcely necessary to observe that the animal, especially in the larger madrepores, as the *Pungia*, most closely resembles the *Actinia* in its general organisation. Cuvier

places the madrepores in the tribe *Lithophyta*, of the family of *Polypi corticati*. The Lithophytes having the common character of the Linnæan genus are now subdivided into the genera *Fungia*, Lam.; *Turbinolia*, Lam.; *Cyclolythus*, Lam.; *Caryophyllæa*, Lam.; *Oculina*, Lam.; *Pæcilopora*, Lam.; *Serialopora*, Lam.; *Astræa*, *Esplanaria*, *Porites*, *Meandrina*, Cuv.; *Pavonia*, Cuv.; *Hydrophora*, Fischer; *Agaricina*, Cuv.; *Sarcinula*, Lam.; *Stylina*, Cuv.; and *Madrepore* proper.

Madreporite. A species of columnar carbonate of lime, found in Norway and Greenland.

Madrier (Fr.). In Military Engineering, a thick plank covered with plates of iron, and having a cavity sufficient to receive the mouth of a petard, with which it is applied against a gate or any other obstacle intended to be broken down. Also, the flat beams laid in the bottom of a moat or ditch to support the wall. There are also madriers lined with tin and covered with earth, to form roofs over certain portions of military works, in order to afford protection against fires in lodgements, &c.

Madrigal (Ital. madrigale). One of the lesser kind of poems, usually consisting of fewer verses than the sonnet or roundelay. In its composition the fancy and convenience of the poet are not subjected to very strict rules, rhymes and verses of different species being often intermixed. The subjects are mostly of a tender and gallant nature; the character often quaint, the expressions marked with great simplicity. Sometimes, however, a loftier and sublimer train of thought finds its way into these compositions, especially among those of the English school, as in the following celebrated specimen, set to music, and perhaps written, by Orlando Gibbons, in 1612:—

Oh! that the learned poets of this time,
Who in a lovesick line so well can speak,
Would not consume good wit in hateful rhyme,
But with deep care some better subject find;
For if their music please in earthly things,
How would it sound if strung with heavenly strings!

Of a lighter and more regular sort, the following may serve for a specimen:—

When Thoralis delights to walk,
The fairies do attend her;
They sweetly sing and sweetly talk,
And sweetly do commend her.
The satyrs leap and dance around,
And make their conges to the ground;
And evermore their song is this,
'Long may'st thou live, fair Thoralis!'

In a musical sense, a madrigal is a vocal composition in several parts, in antique figured contrapuntal style, and intended to be sung by many voices to each part.

Simple madrigals appeared about the beginning of the sixteenth century, during which, and the whole of that following, the style was particularly cultivated and encouraged. The fashion may now be considered to have passed away, unless we are allowed to consider the English glee an offset from it. The first madrigals were in a style of music very much

resembling that of the church; but they afterwards assumed a character peculiar to themselves, which is strikingly exemplified in those of Luca Marenzio (soon after the time of Palestrina), and after him in the works of Gesualdo, the prince of Venosa, Monteverde, and Mazocchi. It is in their madrigals that the restraints which laboured counterpoint imposed were abandoned, to make way for imitations, canons, and fugues. The style was indeed that of the age, but the subjects were free; and the tender and impassioned poetry adopted was well expressed in the affections of the harmonies employed. The original character gradually became more free, and was carried to its utmost limit in the compositions of the celebrated Alessandro Scarlatti. In England, during the reign of Elizabeth, the composition of the madrigal attained a very high, perhaps the highest, degree of excellence. Our composers were in no respect inferior to those of Italy and the Netherlands, and among them are to be found the names of Orlando Gibbons, Dowland, Wilbye, Ward, Bennett, and Morley.

Maestoso (Ital.). In Music, a direction to the performer that the music to which the word is prefixed is to be performed majestically and with grandeur.

Maestricht Beds. The neighbourhood of Maestricht contains some beds belonging to the chalk, but apparently newer than any part of that rock in England. Of these beds the upper part is coralline, and the lower chert. None of the deposits exactly resemble chalk. Some of the fossils are unquestionably cretaceous, and others are quite distinct from those found in English cretaceous rocks, and indeed more nearly resemble those of the oldest tertiary. At Faroe, in Denmark, beds occur newer than English chalk; and a mass of yellowish pisolitic limestone overlies the chalk in France, near Paris, quite unconformably, and is probably of much newer date, though not tertiary. None of these beds are yet found in England, where perhaps the denudation has been more complete.

These newer deposits must not be confounded with the true chalk of Maestricht, which is of the ordinary kind, and has yielded some remarkable fossils; among the rest, part of the skull of a reptile, of large size, called *Mosasauros*. The cretaceous beds of Western Europe cannot anywhere be regarded as affording passage beds to the older tertiary.

Magazine (Fr. magasin; Span. magacen, perhaps an Arabic word). A receptacle for military stores, but especially for gunpowder. Magazines in a fortress should always be made shell-proof.

MAGAZINE. An apartment in the hold of a ship in which the powder is kept. As lights are not allowed to be burnt here, the light is received from an adjoining apartment, called the *light-room*, through a transparent screen. The principal magazine is in the forehold, but there is usually a small service magazine in

the afterhold. There are appliances for flooding either magazine on the least appearance of fire in its vicinity.

MAGAZINES. In literature, the general designation for the periodical literature of a country, exclusive of the newspaper and review. The peculiar province of the two latter seems to be to give information—the one on politics and passing events, the other on literary and scientific subjects; while that of the magazine is of a more miscellaneous character, embracing all the features of the newspaper and review, but at the same time containing, in the form of tales, sketches, and poetry, &c., a great variety of what may be termed *original* matter, the introduction of which would be foreign to the purposes of the others. The earliest publication of this kind in England was the *Gentleman's Magazine*, which still exists. It appeared in 1731, and the success which followed its establishment immediately called into the field a host of competitors, which have so increased in number and variety as to form an era in literary history. [PERIODICALS; REVIEW.]

Magdeburg, Centuriators of. [CENTURIATORS OF MAGDEBURG.]

Magdeburg Experiment or Hemispheres. A hollow sphere composed of two hemispheres which fit air-tight, intended to show the amount of the air's pressure, by the amount of force with which they are held together after the interior air has been removed by the air-pump. This apparatus was first suggested by Otto Guericke, of Magdeburg, the inventor of the air-pump.

Magellanic Clouds. Two nebulae in the southern hemisphere, first recorded by the navigator Magellan, and named after him. These singular objects were carefully examined by Sir John Herschel during his residence at the Cape of Good Hope from 1834 to 1838, and are minutely described in his *Results of Astronomical Observations*, &c. The greater nebula, or *Nubecula major*, is situated between the meridians of 4 h. 40 m. and 6 h. 0 m., and the parallels of 156° and 162° of North Polar Distance, occupying an area of about 42 square degrees. The lesser, *Nubecula minor*, is situated between the meridians 0 h. 28 m. and 1 h. 15 m., and the parallels of 162° and 165° N.P.D., and covers about ten square degrees. Their general shape is round, or somewhat oval; and the larger, which deviates most from the circular form, exhibits the appearance of an axis of light very ill defined, and by no means strongly distinguished from the general mass which seems to open out at its extremities into somewhat oval sweeps. 'When examined through powerful telescopes,' Sir John observes, 'the constitution of the nebulae, and especially of the *Nubecula major*, is found to be of astonishing complexity. The general ground of both consists of large tracts and patches of nebulosity in every stage of resolution, from light irresolvable with eighteen inches of reflecting aperture, up to perfectly separated stars, like

the Milky Way, and clustering groups sufficiently insulated and condensed to come under the designation of irregular, and in some cases pretty rich clusters. But besides those, there are also nebulae in abundance, both regular and irregular—globular clusters in every state of condensation, and objects of a nebulous character quite peculiar, and which have no analogue in any other region of the heavens. Such is the concentration of the objects, that in the area occupied by the *Nubecula major* not fewer than 278 nebulae and clusters have been enumerated, besides fifty or sixty outliers, which (considering the general barrenness of such objects in the immediate neighbourhood) ought certainly to be reckoned as its appendages, being about six and a half per square degree, which very far exceeds the average of any other, even the most crowded parts of the nebulous heavens. In the *Nubecula minor* the concentration of such objects is less, though still very striking, thirty-seven having been observed within its area, and six adjacent but outlying. The nebulae, then, combine, each within its own area, characters which, in the rest of the heavens, are no less strikingly separated—viz. those of the galactic and the nebular system. Globular clusters (except in one region of small extent) and nebulae of regular elliptic forms are comparatively rare in the Milky Way, and are found congregated in the greatest abundance in a part of the heavens the most remote possible from that circle; whereas, in the nebulae, they are indiscriminately mixed with the general starry ground, and with irregular though small nebulae.' (*Outlines of Astronomy*, p. 613.)

Magenta. One of the red or crimson dyes derived from Aniline.

Magians (Gr. *μάγος*). The hereditary priests among the Persians and Medians are so termed by ancient Greek historians. The name has been derived by modern orientalists from *mog* or *mag*, signifying priest in the Pehlevi language. Zoroaster is designated as the great reformer of the order; but the history and the very existence of that celebrated character are enveloped in complete obscurity. He is generally supposed to have lived at no long period before the age of Cyrus. The most remarkable feature of his doctrine consisted in the two principles of Good and Evil, which were held to divide the dominion of the world, in alternate periods, during its whole predestined duration of 12,000 years. [DUALISM.] The books termed the *Zendavesta*, brought to Europe in the last century by Anquetil du Perron, are supposed by some to contain the essential doctrines of this religion; but their authenticity has been the subject of much discussion. The fire-worshippers of Persia and India still hold them in reverence. [ZENDAVESTA; GURBERS.] Our amplest resources for the study of the religion and character of the ancient magi are to be found in the learned researches of Anquetil. (*Mémoires de l'Acad. des Inscriptions*, vol. xxxiv.)

MAGIC

Magie (Lat. *ars magica, the art of the magi*). Common as the superstitious belief in the possession of such powers has been among all nations hitherto discovered on the globe, the Romans were, perhaps, the most superstitious, in this and other respects, of all people. No American tribe has a more implicit faith in its rude 'medicines' or 'mysteries,' than this great and civilised people had in its auguries and divinations; and it is a remarkable feature in their character, that while their religion prescribed these rites, the popular imagination was always searching after fresh excitement from others, which were not only unauthorised, but condemned by their laws—the practices of the Thessalian witches, the magi, the sorcerers of Egypt and Phrygia, and the numberless other foreign nations with which their dominion brought them in contact. Against these the emperors were continually renewing their ineffectual edicts; and it seems to have been mainly from this circumstance that the idea of magic, as a black and forbidden art, became rooted in the minds of the people of modern Europe. For the northern conquerors held such supernatural power in high respect; and in the East, the favourite land of sorcery and magic, the professors have from time immemorial been regarded rather as venerable than as hateful. Hence, if any systematic account can be attempted of matters which have their foundation in the strange caprices of popular credulity, it may be thought that, in the superstition of the middle ages, *white magic* or *celestial magic*, according to Cornelius Agrippa's division, originated in the North or East; *superstitious* or *diabolical magic* from Roman notions engrafted on Christianity; while *natural magic* arose merely from the disposition among the scientific of those days to take advantage of the vulgar propensity to attribute everything extraordinary to supernatural causes. It is to be observed that among the crusaders, and other Christian warriors of the middle ages, magic was regarded as a peculiar ally of the eastern and northern infidels with whom they were in contact. The inhospitable North was peopled by their imagination with enchanted castles and spectral illusions (Scott's *Demonology and Witchcraft*, letter v.); and Froissart gives a most picturesque account of the spells which were resorted to by Mohammedan warriors in their conflicts with the soldiers of the cross. In the romances founded on these historical encounters there is usually a good magician or witch (not the degraded witch of vulgar superstition, but the French *fée*, Italian *fata*) enlisted in the Christian party; evil necromancers in that of the infidels. Thus, in *Ariosto*, Malagigi and Melissa aid the one side, and Atlas the other. The notion of *white witches*, or beneficent wizards, was assiduously kept up by those impostors who wished to profit by the public credulity, and yet avoid the penalties awarded by the church; and in the church itself there was a contest continually maintained, whether magic, practised

through laborious research and study of the celestial influences or intermediate spirits, was lawful. But the public opinion always inclined the other way; and the magicians of highest pretensions were always in danger of being classed with the hated necromancers who derived their power from compact with the devil. Among the earliest fables respecting the higher order of European magicians is that of Virgil, the Latin poet, turned into a wizard by popular belief, which dates as high as the eleventh or twelfth century. Robert of Lincoln (Grossetête), Michel Scot, Albertus Magnus, and the famous Roger Bacon, all lived in the thirteenth. Of these the first was a church reformer, who seems to have lain under the imputation of magic merely on account of the displeasure with which he was regarded by the orthodox. Michel Scot is almost wholly a traditional personage; that is, his real history is scarcely known: the European reputation which he had achieved as a wizard is proved by the high mention of him in the *Inferno* of Dante, who condemns all magicians indiscriminately to endless punishment. It is difficult to say that Roger Bacon ever gave any cause by pretensions of his own, like so many other eminent natural philosophers of early time, to those charges of magic to which his high genius subjected him. Perhaps Sir F. Palgrave, in his amusing fiction (*The Merchant and Friar*), was not far wrong in representing him as partly dazzled by an inability to comprehend the real extent of those extraordinary discoveries which were opening upon him, and partly owing his magical reputation to the impostures practised by his servants in his name. Albertus Magnus, a Dominican, and a celebrated magician in his time, lies more justly open to the charge of quackery. It seems to have been after this time, about the fourteenth century, that magic rose for a season into high repute as a lawful art, and sovereigns had professed magicians and astrologers attached to them. The extraordinary tales related of some of these point evidently to results effected by means of legerdemain; the feats of Ziiito, sorcerer to Wenceslas, king of Bohemia (Godwin, *Lives of the Necromancers*, p. 273), are exactly a counterpart of what Tavernier saw at the court of the Great Mogul. The higher order of magicians maintained their pretensions with difficulty after the revival of letters. Yet the three most famous of all belong to the commencement of that era: Doctor Faustus (if that personage be not altogether traditional), Cornelius Agrippa, and Paracelsus. It will, however, be evident to anyone who reads their history, that the belief in *celestial magic* was with difficulty maintained in their days, while that in *necromancy* and *witchcraft* remained almost as strong as ever. There is a good deal of mystery about the character of the famous Dr. Dee; and it does not appear distinctly how far he pretended to those powers which are ascribed to him in that dreary work entitled, *A True*

MAGIC LANTERN

Relation of what passed between Dr. Des and some Spirits, published by Marie Casaubon, in 1659. In 1634, the French curate, Urbain Grandier, was burnt for sorcery at Loudun; in 1640, Dr. Lamb was murdered by the London mob; and these are nearly the latest instances of distinguished magicians, while the degraded belief in witchcraft lasted much longer. As to *natural magic*, or the production of singular phenomena by natural means, see Brewster's *Letters on Natural Magic*. [WITCHCRAFT.]

Magic Lantern. An optical instrument, by means of which small figures, painted with transparent varnish on slides of glass, are represented on a wall or screen considerably magnified. It is generally used as a toy, and affords amusement from the grotesque character of the figures; but is also employed to enlarge the diagrams employed in astronomical and other lectures, so as to be seen by an audience: for which purpose it is well adapted, both by its portability and the small cost of the whole apparatus. The principle of its construction is very simple. A lamp L, with a powerful Argand burner, is placed within a closed lantern, and in the focus of a concave mirror M.N. At the opposite

side of the lantern is fixed a tube A.B, containing a hemispherical illuminating lens A, and a convex lens B; and between A and B is a slit C.D, through which the sliders of painted glass are introduced. In this manner the picture is placed in the axis of the tube, and strongly illuminated, in consequence of the light being concentrated upon it by the mirror. The picture being also in one of the conjugate foci of the lens B, an enlarged image of it is formed upon a wall or screen E.F at some distance behind. The tube A.B is made to pull out, so that the distance of the lens B from the slider can be increased or diminished at pleasure, and consequently an image formed of any size within moderate limits, by increasing or diminishing the distance between the lantern and the screen. The magic lantern was invented by Athanasius Kircher.

Magic Square. A term used to denote a series of numbers in arithmetical progression, arranged in the equal cells of a square in such a manner that the vertical, horizontal, and diagonal columns give the same sum. For example, let the first sixteen numbers be arranged as in the annexed table, and a magic square will be produced; for the numbers in

1	16	11	6
13	4	7	10
8	9	14	3
12	5	2	15

each vertical column, in each horizontal column, and in the two diagonal columns, being added

MAGISTRY

together, give the same sum, namely 34. This is, however, only one of a great number of ways in which the same numbers may be arranged so as to fulfil the conditions. Frenicle (*Diverses Ouvrages*, Paris 1693) has shown that there are 878 such arrangements. Emanuel Moscopolus, a Greek author of the fourteenth or fifteenth century, is the first who is known to have treated of magic squares, and to have given rules for their construction. The principal authors who have written on the subject are Stifel, Leibnitz, Bachet, Poignard, Lahire, Ozanam, Franklin, &c. For the history of the subject, see Montucla, vol. i. p. 346, or Hutton's *Dictionary*; and for the methods of constructing them, Ozanam's or Hutton's *Mathematical Recreations*.

Maglip. When linseed oil and mastic varnish are mixed together, they produce a gelatinous compound known under the above name, and used by artists as a vehicle for colours.

Magilus. A name given by Montfort to a genus of Tubulibranchiate Gastropods in the system of Cuvier, chiefly remarkable for the form, length, and solidity of their shell. The modifications of this dermal production are due in the present instance, in great measure, to the accidental circumstances of the locality in which the growth of the individual proceeds. The young *Magilus* commences its career in a bed of lithophytous coral, and during the early and rapid stages of its development secretes its calcareous covering in the ordinary form of a spiral univalve; but the growth of the surrounding madrepore soon surpasses its own, and it is compelled to bring its oral and respiratory orifices, by the most direct route, to the level of the surrounding coral. While this change of place is being effected, the mollusc continues to secrete fresh layers of shell coextensive with its own advance, and to fill up the deserted part of the shell with a solid deposit of a dense, semivitreous, and subtransparent carbonate of lime, and finally produces an elongated, slightly wavy, tubular shell, with the apex sculptured in the form of a spiral univalve, and the opposite end excavated to a certain depth for the lodgement of the animal. The tube is characterised by being longitudinally carinated.

Magister (Lat. contracted Mister or Mr.). An appellation given, in the middle ages, to those persons who had attained some degree of literary or scientific eminence—in scientiâ aliquâ præsertim literariâ. It is given in our universities to those who have taken the highest degree in the Faculty of Arts. It was equivalent to the modern title of doctor.

Magister Equitum (Lat. master of the horse). An officer among the Romans subordinate to the dictator, by whom he was usually elected. [DICTATOR.]

Magistry. The old chemists generally applied this term to *precipitates* produced by the dilution of certain solutions with water: such as magistry of *bismuth*, which is an insoluble subnitrate, obtained by pouring nitrate

MAGISTRAL FORMULÆ

of bismuth into water; and magistery of *ben-zoin*, formed by pouring an alcoholic solution of benzoïn into water.

Magistral Formulæ. A term applied to extemporaneous prescriptions, as opposed to official formulæ, or those ordered in the *Pharmacopœia* and kept ready prepared in the shops.

Magistral Line or Guiding Line. In Fortification, usually the line of the top of the scarp of a work.

Magistrate (Lat. *magistratus*). A general designation of those public officers to whom the executive power of the law is committed, either wholly or in part. Under the various heads, the reader will find a notice of the principal magistrates of all ages and countries.

Magma (Gr. from *μάζωω*, *I knead*). A thick ointment or confection. The term is also applied to any pulpy or pasty mixtures, or precipitates.

Magna Charta. [*CHARTA, MAGNA.*]

Magnates (Lat. found only in inscriptions). In Hungary at this day, and formerly also in Poland, the title of the noble estate in the national representation. [*STATES.*] The Hungarian magnates are divided into greater and lesser; certain high state officers belonging to the first class, the counts and barons of the kingdom to the second.

Magnesia (MgO). A white, tasteless, earthy substance, usually obtained by exposing its hydrated carbonate to a red heat. Its specific gravity is about 3.4. It is almost insoluble: but when moistened and put upon turmeric paper it reddens it: this sometimes depends upon a trace of lime. In commerce, pure magnesia is generally distinguished by the term *calcined magnesia*; and the hydrated carbonate of magnesia, obtained by precipitating a solution of sulphate of magnesia by carbonate of soda and washing and drying the precipitate, goes by the name of *magnesia*, or *magnesia alba*. The chief use of magnesia and its carbonate is in medicine. *Sulphate of magnesia* is obtained by evaporating the residue of seawater after the common salt has been separated, or by adding sulphuric acid to *bittern*, and evaporating, so as to obtain the resulting sulphate of magnesia. This salt is also obtained by the action of dilute sulphuric acid on magnesian limestone, and it is not uncommon in mineral waters: it was formerly procured from certain springs near Epsom, in Surrey, and was hence termed *Epsom salt*. It crystallises in four-sided prisms with dihedral summits. Its crystals are soluble in their weight of water at 60°, and in three-fourths their weight at 212°. They melt when heated, and gradually lose their water of crystallisation. They consist of 20 magnesia, 40 sulphuric acid, and 63 water. This salt is a useful purgative in medicine, and is the chief source of the other forms of magnesia. All the magnesian salts have a peculiar bitterish taste; hence the German term *bittererde*, *bitter-earth*. Magnesia is found native in the state of hydrate and carbonate; it exists as a component part of several minerals, and

MAGNESIUM

many of them are soft or soapy to the touch. A native hydrate of magnesia occurs in the serpentine rocks at Hoboken, in New Jersey, and also in Unst, one of the Shetland Isles. It has a pale greenish hue and a soft lamellar texture.

Magnesian Limestone. A mixed carbonate of lime and magnesia is sometimes met with in rock masses putting on the appearance of common limestone, but generally harder and heavier. When crystalline, it is called *dolomite*, but the crystallisation is generally imperfect. Magnesian limestone is comparatively slowly soluble in dilute acids, and in this respect is unlike the common limestones. Nevertheless, as a building stone, it appears to be less fitted for London use than many of the ordinary limestones.

Geologically, the magnesian limestones occupy a definite position among the newest palæozoic rocks. This part of the series is known as Permian, the most important features of the rock being developed in the kingdom of Perm in Russia.

Physically, the magnesian limestone is in many parts of England a cliff often steeply scarped, overhanging the coal measures. Parts of it seem to have been a coral deposit built on the edges of coal measures, but these have since been altered chemically perhaps by magnesian vapours. Fossil fish are common in some parts of the series, and a highly bituminous schist containing argentiferous copper (the *Kupfer schiefer* of German geologists) is characteristic of certain deposits at the base of the series developed in Germany.

Magnesite. Native carbonate of magnesia. It forms an immense bed at Bolton in Canada, and also occurs extensively in Greece.

Magnesium. The metallic base of magnesia (represented by the symbol Mg, and the equivalent 12) was discovered by Davy in 1808, who obtained it by electrifying mercury in contact with magnesia, and also by passing the vapour of potassium over magnesia at a white heat. In 1830, Bussy obtained it by the decomposition of chloride of magnesium by potassium. It has since been prepared in large quantities, by the action of sodium on chloride of magnesium, and is now manufactured for commercial purposes. Magnesium is a white metal, of the specific gravity of about 1.75: it may be drawn into wire and laminated; it melts and volatilises at about the same temperature as zinc, i.e. at a bright red heat. It is unchanged in dry air, and is only slowly oxidised in damp air; it does not decompose water and liberate hydrogen at common temperatures, but is rapidly acted upon by dilute acids. Heated to redness in the air, it burns with a dazzling bluish white light, rich in the chemical rays, so that its flame has been very successfully applied to the purposes of photography; it readily combines with the halogens, and forms a nitride with nitrogen. Magnesia is its only oxide, which is constituted of 12 of magnesium and 8 of oxygen = 20 magnesia.

MAGNET

Natural. One of the native oxides of iron is capable of being magnetically excited, which excitement is retained by it as tenaciously as by steel. Now as the natural blocks of this magnetic substance have lain for ages in nearly the same position with regard to the magnetic meridian, they have acquired magnetic polarity; in other words, they have become natural magnets, and retain this character after removal from the stratum in which they are found. The natural magnet is usually of a dark-grey hue, and has a dull metallic lustre. It is found in considerable masses in the iron mines of Sweden and Norway; in the Isle of Elbe; in different parts of Arabia, China, Siam, and the Philippine Islands. Small magnets are also occasionally, though rarely, met with among the iron ores of this country.

The earlier navigators believed that the magnet pointed always to the north pole of the earth; and that therefore by means of it they could always at once tell the direction of their meridian, and consequently in what direction they were sailing. It was hence called the *loadstone* or *leading-stone*.

The employment of the loadstone itself for the purposes of navigation has long been laid aside; as *artificial magnets* can be constructed having a much greater intensity of directive power. [MAGNETISM.]

Magnetic Compasses. [COMPASS.]

Magnetic Compensator. A contrivance devised by Mr. Barlow, but now seldom used, for eliminating the influence of a ship's guns and other iron in deranging the bearings of the compass. It consists of a plate or combination of plates of iron placed near the binnacle, so as to counteract, by an equal and opposite attraction, that of the rest of the iron on board the vessel. Mr. Airy (*Philosophical Transactions* 1839) has investigated the law of disturbance in the case of vessels built of iron, and shown that the disturbing force consists of a very large force of permanent magnetism in the rolled and hardened plates employed in the construction of the vessel, and a very small force of induced magnetism, which changes with the place of the ship, or rather with the varying circumstances of terrestrial magnetism by which it is produced. Mr. Airy has given a set of practical rules for correcting the disturbing forces by means of two powerful magnets placed at right angles to each other below the compass, and a box of small iron chain, which is used instead of Barlow's correcting plate.

Since, however, both the disturbing magnetic elements are liable to gradual or even sudden variation, it is absolutely necessary that the accuracy of the compensation should be frequently tested. The use of iron in ship building and for the plating of vessels of war has rendered a re-investigation of this matter necessary. Recent valuable contributions to our knowledge of the subject will be found in the *Proceedings of the Royal Society*, vol. xiv. pp. 186, 300. [DEVIATION OF THE COMPASS.]

Magnetic Iron-ore. [MAGNETITE.]

MAGNETISM

Magnetic Needle. A small bar of hard steel suspended by its centre, and magnetised, which shows the direction of the resultant of the magnetic forces at the place of observation. [COMPASS; DIVERSE NAMES.]

Magnetic Pyrites. Native sulphide of iron, so called in consequence of its attracting the magnetic needle. It generally occurs massive and amorphous, with a granular structure, but sometimes (though rarely) crystallised.

Magnetic Tube. [TUBE.]

Magnetism. The science which investigates the phenomena presented by natural and artificial magnets, and the laws by which they are connected. The following brief explanation of it under both aspects may serve to render the subject generally intelligible; but it is impossible to give more than the essential phenomena and the general laws, without descending to the detail of particular cases. For further information reference may be made to the excellent compendium of Dr. Rogee, in the *Library of Useful Knowledge*; to Barlow's *Magnetic Attractions* (2nd ed.), and 'Treatise on Magnetism' in the *Encyclopædia Metropolitana*; Sir D. Brewster's 'Treatise on Magnetism' in the *Ency. Brit.*; Gilbert, *De Magnete*, 1600, folio; Robison's *Mechanical Philosophy*; Biot, *Traité de Physique*, tom. iii.; Pouillet, *Éléments de Physique*; Becquerel, *Traité d'Électricité et de Magnétisme*; Faraday's *Experimental Researches*; Watt's *Dictionary of Chemistry*, art. 'Magnetism'; and various papers in the *Transactions of the Royal Society of London and Edinburgh*.

If a nicely balanced piece of steel be suspended from its middle by a piece of untwisted silk, or allowed to rest upon a pivot, free to turn in all directions, both horizontally and vertically; and if it be then magnetised by any of the methods hereafter described, it will turn itself into one particular position, and if disturbed by any means it will return invariably to the same as its position of repose. The horizontal angle which it makes with the meridian is called its *variation*, or its *declination*; and the vertical angle which it makes with the horizon its *dip* or *inclination*.

On the Formation of Artificial Magnets.—1. If a steel bar be held in the natural direction of the needle, and two or three smart blows be given at the upper end with a hammer, it will become a permanent, though feeble, magnet.

2. If the end of a steel bar be placed in contact with one of the poles of a magnet, it will become permanently magnetic by induction. A better plan is to place the bar in a line between the opposite poles of two magnets of great intensity.

3. Lay the bar flat on a table, and draw a magnet (placed upright upon the centre of it) several times to one end, always the same way. Or take two magnets, and lay them horizontally upon the bar to be impregnated, having their dissimilar ends in contact over its middle; and slide each towards the end of the bar. This must be repeated several times. Or,

MAGNETISM

again, instead of laying them horizontally, hold them in any angle of inclination (each in the same angle, estimated from the perpendicular to the middle of the bar), and draw them several times along towards the ends, without varying their inclinations.

The above methods were those originally employed; but when the principles of magnetic induction came to be better understood, more complicated but more effective processes were invented, for the explanation of which reference must be made to works expressly on the subject. (*Brewster's Treatise on Magnetism.*) Those more complicated processes may be greatly simplified by the substitution of a magnet in the form of a horse-shoe for the compound magnets. If placed at once in the middle of the needle to be magnetised, with the poles turned in a direction the reverse of the poles intended to be given to the needle, and then moved backwards and forwards along the surface of the needle, taking care to pass over each half of it an equal number of times, and repeating the same operation on the other side, the needle is speedily and effectually rendered magnetic. This is by far the simplest mode of magnetising; and it may be considered as a method by induction, the induction being accelerated by the friction.

On the principal Phenomena exhibited by Artificial Magnets.—In the following phenomena the point of the needle which dips below the horizon, and points to the westward of the meridian, is called the *north pole* of the needle, and the elevated one the *south pole*. When the horizontal needle is used, the same terms apply; the end which varies westward being the north pole, and the other the south pole.

Phenomenon 1. If either pole of a magnet be brought near any small piece of soft unmagnetised iron, it will be found to attract it. Iron filings, for instance, are immediately collected together when a magnet is placed among them; and they adhere to it when lifted up, and more especially about the poles of the magnet, in thick clusters. About the intermediate parts the number that adhere is much less than nearer the ends; and in every magnet there is a part to which the filings have no tendency to adhere at all. It thus appears that the magnetic forces, whatever be their nature, are concentrated near the extremities of the magnet; and diminish in intensity as they recede from those extremities.

Phenomenon 2. When, instead of fragments of iron, we substitute a rectangular or cylindrical bar of soft unmagnetised iron, the magnet and the iron will be mutually attracted towards each other. The best mode of exhibiting this is to suspend them by threads of untwisted silk at the appropriate distances, as the friction which they would undergo in sliding on a table is thus removed. It will be found that the ends which are nearest to each other will tend to coalesce. If another iron body be brought near the former in this state of the apparatus, the first iron will be found to be converted

into a *temporary magnet* also; and, in like manner, the second piece of iron may be proved to have become likewise a temporary magnet; and then the third, and so on. The intensity of attraction and repulsion is, however, weaker in each in succession, till at length it becomes insensible. This is prettily exhibited by attaching a key to a magnet, a nail to the key, a smaller nail to that, a sewing needle to the smaller nail, and so on, as long as there is sufficient induced magnetic force to sustain the series in a state of suspension. The iron is said to be converted into a magnet; or to be *magnetised by induction*.

Phenomenon 3. If two magnets be suspended, as in the last experiment, it will be found that the two north poles repel each other, and the two south poles repel each other; but the north pole of the one and the south pole of the other mutually attract each other. They will, in consequence of this mutual action upon each other, take positions *generally* different from those which they would each take in the absence of each other.

Phenomenon 4. If the poles of the successive induced magnets spoken of in Phenomenon 3 be examined as to their nature, by means of their action on the poles of a small magnetic needle, it will be found that each of them is a distinct magnet, each consecutive pair of them having their dissimilar poles in contact. This is known at once by observing which end of the needle is attracted before the next piece of iron is put on, and which after it is added, the needle being applied near the untouched end of the iron.

If, moreover, the pieces of iron be laid on a table and not in contact, the same phenomena will be observed on the application of the trial needle near their extremities.

Phenomenon 5. If the iron be removed, it instantly ceases to be magnetic, and may have its position reversed with precisely the same effect as before, each phenomenon taking place now at the end opposite to that where it was exhibited before; and this will be the case, however long the apparatus has been allowed to remain in the position spoken of. If, however, pieces of steel be employed, the inductive influence is less than in the iron whilst, instead of losing its magnetism instantaneously, as the iron did, it retains a portion of it, and becomes itself a permanent magnet. There are indeed few, if any, pieces of iron and steel in which the magnetic force is wholly lost or wholly retained upon removal; but we here speak of the sensible and approximate circumstances of the phenomena.

Phenomenon 6. If a magnet be broken or any way severed, it is converted into two separate magnets; the two ends of the fragments at which the fracture was made being of opposite kinds to the two ends of the whole bar respectively, as if they had been but two magnets united by opposite poles.

Phenomenon 7. If two magnets be brought near each other, their intensity of action on the

MAGNETISM

vibrations of a needle are affected according to the relative positions of the poles, indicating not only that the direction of the quiescent state of the needle is affected (Phenomenon 8), but that the intensity of the magnetic force is also altered. This shows that the magnetised bar itself is affected by the inductive power of the other bar, as soft iron is.

Phenomenon 8. If a mass of soft iron be brought into the vicinity of a magnetic needle, the needle will be *generally* deflected from its natural position in various degrees and directions, according to the form and position of the needle and the mass. When an iron sphere is employed, as a cannon ball, the investigation of the order of the phenomena becomes more simple and easy; and it was by remarking that in this case there was a certain plane in any point of which the needle may be placed with respect to the sphere where the needle would not be at all deflected, that Mr. Barlow was led to prosecute his celebrated experiments on this subject. Mr. Christie remarked that this plane was the plane passing through the centre of the ball, perpendicular to the *natural* direction of the needle itself.

Phenomenon 9. If discs of various metals be put into rapid rotation, they will also deflect the magnetic needle from its natural position. That this is not owing to vibration or vorticity produced in the air, is rendered evident by the same effects taking place in a more intense degree in vacuo than in the open air. The phenomenon itself was first observed by Arago in France; but it has been chiefly investigated in this country by Herschel, Babbage, Christie, Barlow, Faraday, and Harris, to whose memoirs on the subject, in the *Philosophical Transactions*, the reader is especially referred.

Phenomenon 10. Bars which have stood long in a vertical position, as iron railings, &c., are found to have become permanently magnetic. A bar of soft iron, placed in the natural direction of the magnetic needle, acquires temporary magnetism; and if a bar of steel be left there for a sufficient time, it becomes a permanent magnet. These facts show that the earth itself is a great magnet, and converts the others into magnets by induction. This was observed so far back as the time of Dr. Gilbert; and it is remarkable that, whilst his great contemporary Lord Bacon was perceptively urging the new organon in philosophy, Gilbert was actually putting it into the most careful practice. The doctrine of terrestrial induction, as taught by Gilbert, is the doctrine of the present hour, and with scarcely a single improvement in the whole range of the theory.

The foregoing contain the most important phenomena of magnetism which depend upon terrestrial influence merely: those which depend upon electrical influence will be found under the head **ELECTRO-MAGNETISM**.

Laws of Magnetic Action.—**Law 1.** The intensity of the attractive force exercised by the north pole of one magnet on the south pole of another, and its repulsive force on the north

pole of the second, varies inversely as the square of the distance of those poles; and the like occurs when we consider the action of the south pole of the first magnet on the north and south poles respectively of the other. The same law, precisely, holds with respect to the attraction of a corpuscle of unmagnetised iron.

This is the fundamental law of the science, and may be considered as the source from which the others flow by mathematical reasoning. It has been determined with great care by several philosophers, but especially Michell and Coulomb, by means of the torsion balance and by the method of oscillations, the squares of the times of oscillation being inversely as the attractive forces.

Law 2. When the needle is very short in comparison with the distance and length of the magnet, and has its centre fixed immovably, but is otherwise at liberty to take any directive position, it will so arrange itself that its line of direction will be in the plane drawn through the two poles of the magnet and its own (the needle's) centre of rotation; and if the line of the needle's direction be produced to meet the magnetic line (or line drawn through the poles), it will divide the latter into segments estimated from the poles, which are in the ratios of the cubes of the distances of the poles from the centre of the needle. When the needle is not small in comparison, as above, the law becomes more complicated.

Law 3. If two magnetic needles be made to vibrate, the intensities of their magnetic forces are as the squares of their number of vibrations made in the same time. This is true, whatever be the planes in which they vibrate, so far as the force is effective in that plane; but for a direct comparison of the ratio of the intensities without further computation, the vibrations of both needles must in both cases be made in the *same plane*. The planes most commonly used for vibration are—the horizontal plane; the plane which has been called the magnetic meridian, or that vertical plane which passes through the natural direction of the needle at the place of observation; and the vertical plane at right angles to this.

Law 4. If the needle be allowed to move vertically in a plane making any angle with the magnetic meridian, the dip in that case is equal to the dip in the magnetic meridian multiplied by the cosine of the inclination of the two planes; and if two planes be taken at right angles, in which the dip is observed, the square of the cotangent of the natural dip at that place is equal to the sum of the squares of the cotangents of the observed dips.

Law 5. The intensity of the horizontal force is equal to the intensity of the whole force multiplied by the cosine of the dip. If, therefore, the same needle be used in all the experiments, and observations be made to determine the dip and horizontal intensity at several different places, the relative intensities of the terrestrial magnetic force can be deduced from those ob-

MAGNETISM

servations, by the three last laws, for each of the places.

The laws according to which magnetic force is influenced by temperature have been investigated chiefly by Coulomb, Kupffer, Barlow, Christie, and Faraday. It appears generally that between the temperature of -3° and $+127^{\circ}$ of Fahrenheit the intensity of magnets decreases as the temperature increases; and that at temperatures above 100° a part of the power of the magnet is permanently destroyed, whilst at a red heat the magnetism disappears altogether.

Magnetism, Animal. This alleged influence, or agent, was first heard of in Vienna about the year 1776, when a person of the name of Anthony Mesmer published a thesis *On the Influence of the Planets on the Human Body*. About the same time a Jesuit, called Father Hehl, imagined that by the help of a loadstone and certain steel plates rendered magnetic he had cured several diseases; and being struck with the analogy of Mesmer's views to his own, they entered into a kind of partnership as joint practitioners, and attracted considerable notice; so that, although they soon quarrelled, their system of treatment had acquired some notoriety and many powerful advocates. Hehl continued to practise this new and occult science in Germany; and Mesmer, in 1778, went to Paris, and in the course of a short time performed such wonderful cures, real or imaginary, that his apartments were daily thronged with patients of all ranks, and fees and reputation poured in from all quarters. He here, however, associated himself with a M. d'Eslon, a medical man, who, being more skilful in the art of pleasing patients than his master, contrived to gain the ascendancy, and so to disgust Mesmer that he was induced to quit Paris for Spa, where, under the pretence of initiating others in the secrets of his trade, he soon raised about 14,000*l.*, with which he retired to his native place (Mersburg in Sualbia), and left magnetism and the magnetisers to their own resources.

To ascertain how far the pretensions of the animal magnetisers were entitled to any attention or support, the French government appointed a committee of scientific and unprejudiced persons to investigate its merits, among whom were Bailly, Franklin, and Lavoisier; and it is curious that their report, which was translated into English, and published here in 1785, is not more frequently quoted. 'This pretended agent,' say they, 'is not magnetism; for on examining the grand reservoir of the fluid by a needle and electrometer, neither magnetism nor electricity could be detected. We tried it upon ourselves and others without effect; and on blinding those who professed great susceptibility of its influence, all its ordinary effects were produced when nothing was done but when they imagined they were magnetised, while none of its effects were produced when they were really magnetised but imagined nothing was done. So also when brought under a magnetised tree;

nothing happened if they thought they were at a distance from it, while they immediately went into violent convulsions when they thought they were near the tree, though really not so. The effects, therefore,' say the commissioners, 'are purely imaginary; and although they have wrought some cures, they are not without danger, for the convulsions sometimes spread among the feeble of body and mind, and especially among women. And, finally, there are parts of the operations which may readily be turned to vicious purposes; and, in fact, immoral practices have already actually grown out of them.'

Although the alleged phenomena of animal magnetism or mesmerism have since been repeatedly investigated, yet little of a tangible or satisfactory nature has been clearly established. In such investigations it is difficult to eliminate sources of error arising from the imagination of the patient, and which have doubtless often led observers astray; but, be the alleged phenomena of mesmerism true or fallacious, it is certain that they have no connection whatever with magnetism.

Magnetism, Terrestrial. During the last quarter of a century immense efforts have been made to determine the phenomena and laws of terrestrial magnetism. The impulse given to the study of this department of science is mainly due to Alexander von Humboldt, who, in 1828, formed an association at Berlin for the purpose of verifying an inference which had been drawn from the comparison of corresponding observations made at London and Upsala by Graham and Celsius in the last century, and more recently at Paris and Kazan by Arago and Kupffer; namely that the irregular movements of the needle take place simultaneously at places very distant from each other. At first the operations were on a very limited scale, being confined to hourly observations on some particular days, previously agreed on, at Berlin and Freyberg; but in the following year the plan received an immense extension in consequence of the establishment by the Russian government of magnetical observatories (acting in co-operation with those of Germany) at St. Petersburg, Kazan, Nicolaieff, and Sitka (on the north-west coast of America); that is to say, across the whole continent of Europe and Asia. A second association was soon after formed at Göttingen by Professor Gauss, by which very important improvements were effected both in the instruments used and the methods of observing, which have been since generally adopted. In 1836 the indefatigable Humboldt addressed a letter to the President of the Royal Society, on the best means of perfecting the knowledge of terrestrial magnetism; and, his suggestions being approved by the council of the society, the government was induced, through the representations of that body, to sanction the establishment, in several of the British colonies, of observatories, equipped with appropriate instruments, and superintended by military or naval officers, with

MAGNETISM

sufficient assistance at their disposal for making continuous *hourly* or *two-hourly* observations of the different magnetic elements. The places selected were Toronto, St. Helena, the Cape of Good Hope, and Hobarton, in Van Diemen's Land; and, as it was considered important to obtain observations in high southern latitudes, the expedition to the Antarctic seas, under the command of Sir James Clarke Ross, was projected and ordered at the same time. The East India Company likewise promised its co-operation by providing for the establishment and maintenance of observatories at Bombay, Madras, Lucknow, Singapore, and Simla; and at home, a magnetical and meteorological department was added to the Royal Observatory at Greenwich. Latterly the British Association Magnetical Observatory at Kew has become the centre of this class of observations, and it has formed the model of other observatories recently established at Coimbra, St. Petersburg, Lisbon, Montreal, the Mauritius, Melbourne, and other places. The observations (made systematically) at the stations first named, according to rules drawn up by a Committee of the Royal Society, were reduced under the superintendence of Colonel (now General) Sabine, at an establishment maintained by the government, at Woolwich. Several volumes of observations have been published, containing a regular series, since 1840, made at Toronto, Hobarton, and St. Helena; and including those made in 1841 and 1842 by the officers of the Antarctic expedition. In addition to these official volumes, General Sabine has also contributed a series of interesting papers to the *Philosophical Transactions* and the *Reports of the British Association*, containing the results deduced from a comparison of the observations at the different places, the latest being in the *Phil. Trans.* for 1864. This important memoir should be read by all interested in this subject.

A magnetical observation is complete when three elements are determined—the *declination* of the magnetic needle, its *inclination*, and the *intensity* of the force. The two latter, however, are not usually observed directly, but in lieu of them the horizontal and vertical components of the intensity are observed, and, from the variations of the two components, the variations of the inclination and of the force itself are computed. The declination and inclination indicate the direction in reference to the horizontal and vertical planes which a freely suspended needle would assume, so that, in fact, the direction of the magnetic force and its intensity are the two elements sought to be determined. The instruments employed are called by the general name of **MAGNETOMETERS** [which see].

In order to obtain a knowledge of the laws of terrestrial magnetism, it is necessary that the mean values of the three elements, and the variations of those elements, should be determined at a great number of points taken all over the earth's surface. For the purpose of

comparison, the points or stations at which the observations have been made are projected on maps, and lines being drawn through those points at which the mean values are the same in respect of each element, a series of curved lines is obtained, which indicate the values of the elements at the intermediate points with more or less accuracy, according to the proximity of the stations at which observations are made. The curves thus traced through the points of equal declination are called *isogonal*; those through the points of equal inclination, *isoclinical*; and those connecting the points of equal force, *isodynamic*.

Declination or Variation.—Although the general direction of the horizontal needle is north and south, there are few places at which it points exactly in the direction of the meridian. At London, and over the greater part of Europe, the north end of the needle declines to the west, while in Siberia and some parts of the North American continent it declines to the east.

The changes which take place in the declination are of three kinds—secular, annual, and diurnal. The laws and period of the secular change are very imperfectly known. At London, in 1550, the declination was $11^{\circ} 17' E.$; about 1660 it was 0° . Soon after that year the needle began to deviate to the west; and the westerly declination continued to increase till 1815, when it seems to have attained its maximum of $24^{\circ} 27' 18''$, inasmuch as it has gradually decreased since that time. The mean declination deduced from the observations at the Greenwich Observatory in 1865 was $20^{\circ} 38'$.

The annual variation of the declination was first remarked at Paris by Cassini. From a comparison of observations made at Paris from 1784 to 1788, and at London from 1793 to 1805, Arago found a minimum of declination towards the vernal equinox, and a maximum towards the summer solstice. But it may be doubted whether these ancient observations were sufficiently accurate to determine this question, more especially as the result is not confirmed by the recent observations in the colonial observatories. At St. Helena and Toronto no variation of the rate of the secular change in the different seasons is perceptible. At Hobarton the east declination appears to be, on the average, somewhat greater in the summer months than in the winter months, but the differences are extremely small.

Diurnal Variation.—The declination is also subject to a diurnal change, which was first remarked by Graham, at London, in 1722. The remark was confirmed by the observations of Celsius, and by Hiorter in Sweden (1740–1746), and subsequently by those of Wargentin, who found that the needle declined towards the west from the hours of eight or nine before noon till one or two after noon, and then towards the east till eight or nine in the evening. The same observers also remarked that the needle was affected by aurora, or polar light, and that in the presence of this phenomenon the

MAGNETISM

change in its mean direction was sometimes as much as 5° in the course of a day. In the *Philosophical Transactions* for 1769 there is a paper by Canton, giving the results of observations on the daily variation during 603 days. On 574 of those days the deviations were regular, and nearly the same as those found by Celsius; on the remaining days they were irregular, and on those days there were displays of aurora. Canton ascribed the diurnal change to the effect of the sun's rays in heating the earth, and thereby diminishing the magnetic force; so that in the morning, when the earth is heated on the eastern side of the meridian, the magnetic force on that side is weakened, and the needle consequently declines to the west; and in the afternoon, as the earth becomes heated on the western side of the meridian, the needle begins to move in the opposite direction, and declines to the eastward of its mean place. Similarly Faraday has ascribed the diurnal variation to the heating of the atmosphere, by which the magnetism of its constituent oxygen is diminished. The amount of the diurnal change is different at different places, and at different seasons of the year. At London, for the years 1817-1819, it was found by Colonel Beaufoy to be from $4'$ to $5'$ in December and January, and above $11'$ in June and August. At the Royal Observatory the mean diurnal range for the year 1846 was, in summer, $15' 14''$; in winter, $11' 53''$; and the mean for the whole year, $13' 34''$. At Toronto and Hobarton the diurnal range is also greatest in the summer months and least in the winter months, and the changes take place at nearly the same hours of local time.

Inclination or Dip.—The inclination has a general dependence on the latitude, but it varies considerably at different places under the same latitude. A line drawn through all those places where the dipping needle becomes horizontal (usually, though perhaps improperly, called the magnetic equator) appears to intersect the equator of the earth in four points. In the Atlantic Ocean, between Africa and America, it lies wholly to the south of the terrestrial equator, its greatest south latitude being about 26° . According to Hansteen the nodes or points intersective with the equator of the earth are on the meridians 22° E., 187° E., 120° W., and 108° W.; but these determinations must be taken as subject to considerable uncertainty, the observations being by no means accordant. The other isoclinical lines follow, with more or less irregularity, the direction of the magnetic equator until a high latitude is attained. In Boothia Felix, in latitude $70^{\circ} 5' 17''$ N., and longitude $96^{\circ} 45' 48''$ W., Sir James Clarke Ross found the dip to be $89^{\circ} 59'$, within a minute of the vertical; and the needle had there altogether lost its directive power. In the southern hemisphere, on board the *Erebus*, in 1841, Sir J. C. Ross observed an inclination of $88^{\circ} 36'$ in latitude $75^{\circ} 22'$ S., and longitude $161^{\circ} 48'$ E. (Sabine, *Phil. Trans.* 1843.) The

places at which the dipping needle becomes exactly vertical, and to which the above most nearly approach, are usually styled the *magnetic poles*; but, as will be seen presently, they not only do not coincide with, but are at a great distance from, the places at which the intensity of the magnetic force is a maximum—a circumstance which it is necessary to keep in mind, as the term *pole* is also frequently applied to the points of greatest force. Like the declination, the dip is subject to secular, annual, and diurnal changes. At London it was observed by Graham, in 1720, to be $74^{\circ} 42'$; and by Captain Kater, in 1830, to be $69^{\circ} 38'$. The mean of the Greenwich observations for 1865 is $68^{\circ} 0'$; whence it appears that the dip at London is diminishing. The annual variation is scarcely perceptible. At Toronto and Hobarton the range of the diurnal variation of the dip is about $1' 26''$.

Intensity.—The absolute intensity of the magnetic force, like the declination and dip, varies at different places, and probably at different times. It is compared at different stations by observing the number of oscillations made in a given time by a magnetic bar suspended horizontally by a fine wire or silk fibre. From the large table of results given by Hansteen, it appears that if the intensity at the magnetic equator in Peru (where it was supposed by Humboldt to be a minimum) be unity, then the intensity at Naples is 1.275, at Marseilles 1.294, at Madrid 1.394, at Paris 1.348, at London 1.370, at Christiania 1.420, in Baffin's Bay (lat. $76^{\circ} 45'$ N., long. $58^{\circ} 20'$ W.) 1.705. The maximum intensity hitherto observed is 2.052, and the minimum 0.706. Both observations were made at places in the southern hemisphere, the former by Sir James Clarke Ross, in lat. $73^{\circ} 47'$ S., long. $171^{\circ} 50'$ E. (of London), where the dip was observed to be $87^{\circ} 4'$; and the latter by Erman, in lat. $19^{\circ} 59'$ S., and long. $35^{\circ} 4'$ W., off the eastern coast of Brazil, where the dip is $7^{\circ} 55'$: the two extreme intensities are therefore in the ratio of 1 : 2.906. In both hemispheres there are two points, or rather regions, of maximum intensity, which may be regarded as centres of separate magnetic action. The position of the principal or strongest northern maximum intensity was ascertained by Captain Lefroy, in 1842 and 1843, to be in lat. $52^{\circ} 19'$ N., long. 268° E. (Sabine, *Phil. Trans.* 1846); that of the minor maximum was determined in 1828 and 1829 by Hansteen, and Erman, in the Russian expedition, to be in the meridian of $111^{\circ} 27'$ E. The interval between the two meridians is consequently $270^{\circ} - 111^{\circ} = 159^{\circ}$, so that they are not directly opposite. Both points appear to have undergone progressive changes from west to east, though not at the same rate. In the southern hemisphere the two centres of maximum force are still nearer each other in respect of geographical longitude, and the intensity is greater than in the northern hemisphere. (Sabine, *Phil. Trans.* 1850.) The isodynamic lines are in general nearly parallel to each other, and also to the

MAGNETISM

isoclinical lines, though at some particular places the two sets of lines are nearly at right angles. The intensity does not appear to be affected by elevation above the surface.

Simultaneous Perturbations.—In the volume of Hobarton Observations, 1841 to 1848, Colonel (now General) Sabine gives an interesting comparison of the simultaneous affections of the three elements at Hobarton and Toronto, on one of Gauss's term days, April 21, 1842, these two stations being specially selected for comparison as being geographically situated at nearly opposite points of the globe. The result showed that the amount of disturbance on this day was nearly the same at both stations, and that the instants of extreme disturbance are not unfrequently as nearly identical at both as the nature of the observations enables us to determine. The inference is, that many of the perturbations or particular disturbances observed must be regarded as general affections of the whole globe, manifesting themselves at stations the most remote from each other.

Theory.—Mr. Balfour Stewart recently delivered a valuable discourse on this subject at the Royal Institution, from which the following remarks are extracted, as they show at once the mode of investigation now pursued, and the theory now generally accepted. (*Proceedings of the Royal Institution for 1863.*)

'Gauss, who has done so much to further the science of magnetism, showed, by means of a preconceived system of observation, that magnetic storms affected the needle at Göttingen and at other stations in Europe at precisely the same moment of absolute time; and after the establishment of the colonial observatories, it was found by General Sabine that the needle was affected in Toronto at precisely the moment when it was disturbed at Göttingen. Nor is it too much to say, with our present knowledge, that these remarkable disturbances break out at the same moment over every portion of our globe.

'Having thus shown that these phenomena are cosmical in their character, the next point of interest is their connection with the sun. This has been placed beyond doubt chiefly through the labours of General Sabine, who found at Toronto and elsewhere that magnetic disturbances obey a law of hours. Mr. Broun also showed the same thing from his observation of the needle at Makerstoun, in Scotland. It may be instructive to point out how this proof was deduced from the colonial observations; and to make the matter plain, let us refer to an imaginary case in the familiar science of meteorology. Suppose that while an observer is watching his thermometer there is a sudden influx of cold weather, and that it is wished to estimate the influence of this upon the thermometer on a given day and at a given hour on that day, what must the observer do? He must endeavour to ascertain, by the best possible means, what indication the thermometer would have afforded at that specified day and hour had there been no cold

weather. Comparing this with the actual height of the mercury, and deducting the one from the other, he would clearly obtain a measure of the effect of the cold weather upon the thermometer.

'A similar course was pursued by General Sabine in discussing the colonial magnetic observations, with the object of deducing the laws of disturbances. It was first necessary to ascertain by the best possible means what position the magnet would have assumed at any particular day and hour, had there been no disturbances. Calling this the normal value, the next course was to group together, as disturbed, all those positions of the magnet which differed from the normal by more than a certain small quantity. The necessity for this separation will become evident when it is remarked that the disturbed and the regular observations have different hourly turning-points, and obey very different laws. Thus a disentanglement was effected, which was accomplished by the employment of a separating value. The selection of this value is to some extent arbitrary, but it was shown by reference to a diagram that the disturbance law at Kew was virtually the same, whether this were deduced (in the case of the declination) from ninety-five days of principal disturbances or from all disturbed observations which differ from the normal by more than $3^{\circ}3'$. It was also shown from the same diagram that easterly disturbances prevail at Kew during certain hours of the day, and westerly disturbances at certain other hours, thus exhibiting a daily law, and showing that disturbances are therefore connected with our luminary.

'There is, however, a more interesting and mysterious connection than this. Professor Schwabe, of Dessau, has now for nearly forty years been watching the disc of the sun, and recording the groups of spots which have been visible, and he finds that these have a period of maximum nearly every ten years, two of these periods being the years 1848, 1859. Now it was likewise found by General Sabine, that the aggregate value of magnetic disturbances at Toronto attained a maximum in 1848, nor was he slow to remark that this was also Schwabe's period of maximum sun-spots, and it was afterwards found, by observations made at Kew, that 1859 (another of Schwabe's years) was also a year of maximum magnetic disturbance. This fact is eminently suggestive, and brings us at once into the presence of some great cosmical bond, different from gravitation, adding at the same time additional interest as well as mystery to these perplexing phenomena.

'These are the grounds on which we suspect the sun to be the agent which causes magnetic disturbances, but there is also some reason to believe that on one occasion our luminary was caught in the very act. On the 1st of September 1859, two astronomers, Messrs. Carrington and Hodgson, were independently observing the sun's disc, which exhibited at that time a

MAGNETISM

very large spot, when about a quarter past eleven they noticed a very bright star of light suddenly break out over the spot and move with great velocity across the sun's surface.

'On Mr. Carrington sending afterwards to Kew Observatory, at which place the position of the magnet is recorded continuously by photography, it was found that a magnetic disturbance had broken out at the very moment when this singular appearance had been observed.

'The next point to be noticed is, that magnetic storms are always accompanied by aurora and by earth currents. With regard to the latter of these phenomena, a single word of explanation may be necessary. Earth currents are currents of electricity which traverse the surface of our globe, a portion of which is caught up by the telegraphic wires, which are often thereby seriously disturbed in their communications. A table was then referred to which showed that aurora and earth currents have the same ten-yearly period as sun-spots and magnetic disturbances, so that a bond of union exists between those four phenomena.

'The question next arises, What is the nature of this bond? Now, with respect to that which connects sun-spots with magnetic disturbances we can as yet form no conjecture; but we may, perhaps, venture an opinion regarding the nature of that which connects together magnetic disturbances, aurora, and earth currents. And here we may remark that this latter bond is the more definitely determined of the two, since the three phenomena which it embraces *invariably occur together*.

'In order to exhibit the evidence upon which this hypothesis rests, it is necessary to refer to what is done at the Kew Observatory.

'Reference was then made to a diagram in which the three curved lines photographed from the magnetometer were exhibited for September 1-2, 1859; and it was seen that about four o'clock in the early morning of September 2, the three components of the earth's magnetism at Kew were simultaneously and abruptly disturbed, and were kept at one side of their normal or undisturbed positions for many hours. During this time there were vivid aurora which extended over the greater part of the globe, and even to as low a latitude as Cuba, and strong earth currents were also observed by Mr. C. V. Walker, on the various telegraphic lines. These currents were found to change their direction every two or three minutes, going alternately from positive to negative, and back again to positive. It is therefore evident that currents varying in this manner could not have been the cause of magnetic disturbances in which the needle was kept on one side of its nominal position for many hours. But the curves of magnetic disturbance further exhibit sharp peaks and hollows, or wavelets, superimposed upon the great disturbance wave, and these wavelets change their direction every two or three minutes, in which respect they are comparable with earth currents. May not

these wavelets be connected with earth currents and aurora; and may not this connection be of the following kind? A peak denotes a small but rapid change of the earth's magnetic force in one direction, and a hollow a similar change in the opposite direction. Now in a Ruhmkorff's coil we have—1st, a soft iron core, with a current circulating round it; 2nd, an insulator round the current; 3rd, a secondary coil above the insulator, containing perhaps several miles of fine wire. In this arrangement we have a discharge between the terminals of the secondary coil every time contact with the primary current is made, and one of an opposite character every time this contact is broken.

'But the chief use of the primary current is to reverse the magnetism of the iron core; and could we reverse this, or even change it rapidly without a primary current, we should have the same effect, that is to say, we should have a secondary current in one direction, when the magnetism of the core was rapidly increased, and one in an opposite direction, when this was rapidly diminished. . . . The body of our earth may be likened to the soft iron core of a Ruhmkorff's machine, in which one of the small curve-peaks already alluded to denotes a rapid change of magnetism in one direction, and a hollow a change of the opposite character. The lower strata of the atmosphere again resemble the insulator of the Ruhmkorff's machine, and the upper and rarer strata the secondary conductor; again, the crust of the earth being permeated with moisture, becomes a conductor, and may therefore also be likened to the secondary coil. Whenever, therefore, we have a curve-rise, that is to say, a sudden change of the earth's magnetism in one direction, we should have in the upper strata of the atmosphere and in the crust of the earth currents of one kind; and when we have a curve-fall or a sudden change of magnetism in the opposite direction, we should have similar currents of an opposite description.

'It need hardly be remarked, that those currents which take place in the upper strata of the atmosphere will form aurora, while those in the crust of the earth will constitute earth currents.

'Now, if this be the nature of that connection which subsists between magnetic disturbances, earth currents, and aurora, may we not extend our enquiries, and ask, If the sun's action is able to create a terrestrial aurora, why may he not also create an aurora in his own atmosphere? It occurred independently to General Sabine, Professor Challis, and Mr. Balfour Stewart, that the red flames visible during a total eclipse may, indeed, be solar aurora. In support of this hypothesis it may be remarked that, during the late total eclipse in Spain, Mr. de la Rue, by means of the Kew photo-heliograph, proved that these red flames belong to the sun, and that they extended in one case to the distance of 70,000 miles beyond his photosphere. But, considering the gravity of the sun, we are naturally unwilling to suppose that there can be any

MAGNETITE

considerable amount of atmosphere at such a distance from his surface; and we are therefore induced to seek for an explanation of these red flames amongst those phenomena which require the smallest possible amount of atmosphere for their manifestation. Now the experiments of Mr. Gassiot and the observed height of the terrestrial aurora alike convince us that this meteor will answer our requirements best. And besides this, the curved appearance of these red flames, and their high actinic power in virtue of which one of them, not visible to the eye, was photographed by Mr. de la Rue, are bonds of union between these and terrestrial auroræ.

‘It has been remarked by General Sabine, that an auroral outburst in the sun may perhaps be responded to simultaneously by the different planets. If this be true, our whole solar system would seem to thrill almost like a living being under the excitement of this mysterious force. It has been likewise found by Mr. Gassiot, that electricity cannot pass through a perfect vacuum, so that perhaps we have only to observe the greatest height attained by a terrestrial aurora and by a solar red flame, in order to be able to assign the limit, not only of our own atmosphere, but also of that of our luminary.

‘One other point remains to be noticed in connection with magnetic disturbances, and this is, that there appear to be two separate disturbing forces, nearly opposite in character, both connected with the sun, which act simultaneously upon the magnet; the position which the latter assumes being due to the combined effect of both. This has been shown to be true by General Sabine, who has observed that the curve which exhibits the daily range of the east component of the disturbing force, is in many places very different in character from that which exhibits the same for the west component. And this difference between the two curves is of one kind at one station, and of another kind at another station. This duality of the disturbing forces may also be observed directly in the Kew disturbance-curves. . . . The attention of foreign men of science has been much directed to the problem of terrestrial magnetism, and five sets of magnetographs, similar to those in operation at the Kew Observatory, have been already procured by foreign governments. These, however, will be placed in the northern hemisphere, and it is to be desired that some of our colonies in the southern hemisphere may come forward in order that by the next epoch of maximum disturbance (1869) there may be such a network of magnetic observatories as may enable us to obtain the solution of this interesting and important problem.’

Magnetite. Magnetic Iron-ore, or Oxidulated Iron. One of the richest and most important of the ores of iron, and that from which the finest kinds of steel are made. It is a widely diffused mineral, and is found abundantly in many localities, especially in Lapland, Norway, Sweden, and Canada, occurring crystallised in iron-black octahedrons and

MAGNETOMETER

dodecahedrons, also massive and in the form of sand.

Magneto-electricity. Under the term ELECTRO-MAGNETISM will be found the description of certain magnetic phenomena produced by electricity. It has been demonstrated by Faraday that electric phenomena may be produced by magnetism, and to these the term *magneto-electricity* has been applied. Let a represent a hollow helix of copper wire covered by

silk, the ends *bc* of which are connected with a delicate galvanometer; and *NS* a powerful bar magnet, which can easily be thrust into and withdrawn from the spiral or helix: it will then be found that every time the magnet is pushed into the helix the galvanometer is deflected in one direction, and each time it is withdrawn it is deflected in the opposite direction. On repeatedly threading the helix with the magnet, the deflection also takes place. Now, as the deflection of the galvanometer can only be produced by the motion of electricity in the helix, it is obvious that an electric current is produced each time that the magnet moves through it; hence as, on the one hand, electricity in motion produces magnetism, so, here, magnetism in motion produces electricity. By causing the pole of a powerful magnet to revolve before a coil of wire, or, what amounts to the same thing, if the coil be made to revolve opposite to the pole of a magnet, an electric current will be established in the coil, which may be made sensible by sparks, shocks, and chemical effects; and by employing a combination of such magnets and coils a current sufficiently powerful for the electric light may be obtained. In magneto-electricity the source of power is the mechanical force used to rotate the magnet or coil. This force may be supplied by muscular action, as in Wheatstone's magneto-electric telegraph instruments; or it may be derived from the steam engine, as in Holmes's magneto-electric light.

Magnetometer. An instrument for measuring the intensity of terrestrial magnetism. The three elements sought to be deduced from magnetic observations are, the declination, the inclination or dip, and the absolute intensity, together with the variations to which they are subject; and each of these elements requires for its determination a peculiar apparatus. When adapted to the purpose of determining the declination, the magnetometer is called a *declination magnetometer*; when for the horizontal and vertical force, they become *horizontal* and *vertical force magnetometers*. From the experience obtained in the British colonial observatories, it appears that these instruments, at least in the form recommended in the *Instructions* drawn up by the Committee of the Royal Society, are liable to certain sources of irregularity; one depending on the liability of the magnetised bar to lose a portion of its magnetism, and others on causes not perfectly understood. (Sabine, *Phil. Trans.* 1850.) At Green-

MAGNETOMOTOR

wich, Kew, and other important magnetical observatories, the magnetometers are self-recording, a mirror attached to them reflecting a beam of light on to photographic paper kept in motion by proper apparatus. For particulars of the construction of these instruments, see Becquerel, *Traité de l'Électricité et du Magnétisme*, vol. vii., and Daguin, *Traité de Physique*, iii. 78.

Magnetometer. A term applied to a voltaic series of two or more large plates, which, producing a great quantity of electricity of low tension, is well adapted to the exhibition of electro-magnetic phenomena.

Magnifying Power. As the *illuminating power* of a telescope or microscope depends upon the aperture of the object-glass, so does the *magnifying power* depend upon the focal length and the *depth* or power of the eyepiece. In the telescope this power is generally limited by the illuminating power, as each increase in the size of the image spreads the light over a larger area, until the image is too dim to be observed. In the microscope, as the light can be increased to almost any extent, the magnifying power is proportioned only to the perfection of the object-glass.

Magnitude (Lat. magnitudo). Size, extent, quantity. This term was originally employed to designate the space occupied by any figure; or, in other words, it was applied to objects strictly termed geometrical, and of three dimensions—length, breadth, and thickness: then it was extended to designate the quantity of any one of these, and also of angular space, or the inclination of two lines to one another; or, again, the compound idea of a solid angle formed by any number of planes meeting in a point. The amount of any one of these, taken in reference to some standard of the same kind of quantity as that spoken of, was called its magnitude. The term was gradually enlarged in its signification, so as to apply to every kind of quantity that admits of exhibition or mensuration, or of which greater or less can be predicated; and in this sense it was used by Euclid.

Magnitude, Apparent. The angular space (plane or solid) under which a body appears when viewed from some distant point. The term is chiefly used in speaking of the celestial bodies, and is then employed to express the plane angle subtended by the diameter of the visual disc of the body. It is also used in many branches of optical science; but always with the same general meaning.

Magnolia (after Pierre Magnol, professor of medicine at Montpellier). A fine genus of trees or shrubs, some of them evergreen, found in North America, Northern India, and China. Many of them are cultivated for their beautiful tulip-like flowers, often of large size, and deliciously fragrant. One evergreen species, *M. grandiflora*, adds to shining laurel-like leaves large white aromatic flowers of great beauty. *M. glauca* is called in America the Swamp Sassafras, and has qualities resembling those of the true Sassafras.

MAID OF HONOUR

Magnoliaceæ (*Magnolia*, one of the genera). A natural order of Exogenous plants of the Ranaï alliance, consisting of trees or shrubs of great beauty, usually with evergreen leaves, and large fragrant flowers. They inhabit the temperate parts of America and Asia, as well as the tropics, and are universal objects of cultivation. The bark of the Tulip-tree, *Liriodendron Tulipifera*, and of some of the true Magnolias, has the reputation of being a good febrifuge. *Drimys Winteri* yields Winter's Bark.

Magpie. A common species of the Crow tribe, *Corvus. Pica* of Linnæus; now the type of a distinct genus, *Pica caudata*. They continue in pairs throughout the year, and prey on a variety of food, chiefly animal, as the young of hares, rabbits, and feathered game, young poultry, eggs, carrion, and insects; lastly, fruit and grain.

Magney. The American Aloe, *Agave americana*.

Mahābhārata. The name of one of the great Indian epic poems, the chief subject of which is a long civil war between two dynasties of ancient India, the Kurus and Pandus. This poem, which embraces the whole circle of Indian mythology, has been recast by later editors, evidently Brahmans, who have in great part changed its epic into a didactic character. This collection of poems is more recent than the Veda, for the war, which is its principal subject, is not known in the latter. (Max Müller, *History of Sanscrit Literature*, pp. 42–48 &c.) Many episodes from the *Mahābhārata* have been ably translated by some of our most celebrated Orientalists; and parts of the original have been published at different periods in Germany. [RAMAYANA.]

Mahadeva. In the Mythology of the Hindus, the name of a deity who shares the attributes of Siva in the later Indian Trimurti, or Trinity. These attributes vary greatly, Mahadeva being regarded as a generator as well as a destroyer. In the earlier Vedic writings Mahadeva, like Rudra, is the name of a god who is described under characters as various as those which are assumed by Heracles and Phœbus in Hellenic Mythology. (Muir, *Sanscrit Texts*, part iv. ch. iii. sect. 7.)

Maharanga (its Nepalese name). A genus of *Boraginaceæ*, of which a Nepal species, *M. Emodi*, yields thick fleshy deep purple roots, which impart a brilliant red to oils. They are the Rutton roots of the Indian bazaars, and oil coloured by them is used for staining wood of a mahogany colour.

Mahogany. The timber of the tree known as *Swietenia Mahagoni*. This is the true or Spanish mahogany. Indian mahogany comes from *Cedrela Toona*; and African from *Kaya senegalensis*.

Mahometanism. [MOHAMMEDANISM.]

Maia. In Greek Mythology—1. A daughter of Atlas and Pleione, and mother of Hermes. 2. A Roman divinity, also called Majesta.

Maid of Honour. An attendant of high rank on the person of the queen. [HOUSEHOLD.]

MAIDÆ

A family of crabs (Brachyurous Crustaceans), of which the genus *Mais* is the type. The form of the shell is ovoid; the manus and the preceding joint are nearly of the same length. The species called *Mais Squinado* is occasionally taken on our own coasts, as well as on those of France and of the Mediterranean. It is commonly called the *sea spider*.

Maiden. The name given in Scotland to a sharp-edged instrument, formerly used for the beheading of criminals. It resembles in its construction the *guillotine* of the French. [GUILLOTINE.]

Maidenhair Fern. The *Adiantum Capillus Veneris*; a fern found in many parts of Europe on damp shaded rocks. It formed an ingredient in the syrup of capillaire of old pharmacy. The article now sold under that name is simple syrup flavoured by orange-flower water.

Mail (Fr. *maille*). A small piece of metal or money; but the word is applied collectively to defensive armour formed of iron rings or round meshes. [HAUBERK.]

MAIL (Fr. *malle*). A word which signified originally the bag containing letters forwarded by government for the public convenience; but it was soon afterwards extended to the letters themselves, and it is now used also for the conveyance in which they are forwarded. [POST OFFICE.]

Mails or Mailles. In Scottish Law, the rents of an estate. (Silver halfpence, in England, were anciently called *mailes*.) In the northern counties of England, and in Scotland, payments made by the occupiers or owners of lands to persons in league with the various classes of freebooters who infested the country were termed *black mail*. To take it was made a capital felony by stat. 43 Eliz. c. 13.

Mailm or Mayhem. In old English Jurisprudence, a wound by which anyone was so disabled as to be less fit to defend himself in fight; and therefore distinguished from an injury which merely disfigured. Appeal of mayhem was abolished, with other criminal appeals, by 59 Geo. III. c. 46.

Main. In a vessel with three masts, the centre mast, hatchway, &c. If she have but two masts, it is the aftermost; unless the vessel be a yawl or ketch, when the mast nearest the bow is the mainmast. In one-masted vessels, if the mast be given a name, it is the mainmast. In all rigs the mainmast is the principal and tallest mast.

Main Beam. In Machinery, the term *main beam* is applied to the beam set in vibration by the piston rod at the one end and connected with the main connecting rod at the other. It has an alternative circular motion about a fixed axle, and serves to transmit to all the machinery the force which it receives at its end. It is generally executed in cast iron, but of late years wrought iron has been frequently employed in this part of machinery. The old steam engines had main beams of wood, which

MAIZE

is still largely employed for that purpose in the United States. The connecting rod of the pumps to feed the boiler and to work the air pumps are usually attached to the main beam.

Main Centre. In side lever engines, the shaft upon which the side beams vibrate is called the *main centre*; the shaft on which the beam of a vertical engine describes its motion is also so called.

Main Connecting Rod. The connection between the end of the balance or main beam of an engine and the shaft from which the motion is communicated to the machinery that forms part of the assemblage. It is usually formed of cast or wrought iron, or in old engines it is even executed in wood. At one end it is keyed on to the balance beam, and at the other to a crank immediately connected with the first motion shaft.

Main Link. The term used in Machinery to express the link or the bar connecting the head of the piston with the parallel motion of the balance beam of a steam engine.

Main Pedestal. In Steam Engines, the main pedestals are the parts which are introduced upon the top of the framing for the purpose of bearing the main centres of the balance beam; the points of support of the wheels of a marine steam engine are also so called. They are of cast iron, usually planed and carefully fixed on the framing, and have a brass or gun-metal bush to diminish the friction.

Mainspring of a Watch. [HOROLOGY.]

Maintenance (Fr. *maintenir*, from Lat. *manu tenere*, to hold by the hand). In Law, an officious intermeddling in a suit that in no way belongs to one, by maintaining and assisting either party with money, or otherwise to prosecute or defend it. The punishment by common law is fine and imprisonment, and by 32 Hen. VIII. c. 9 a forfeiture of ten pounds.

Maintenance, Cap of. A cap of dignity, anciently belonging to the rank of a duke; termed by the French *bonnet ducal*. The lord mayor's fur cap is also called a cap of maintenance.

Maize (*mais*, the American name). A kind of corn, commonly called Indian corn, consisting of the grain of the plant named by Linnaeus *Zea Mays*, which is extensively cultivated for food. Like other corn, it is a species of grass, whose albumen is sufficiently large and farinaceous to be ground into flour. In the Maize the grains are unusually large, compressed, and packed closely in regular parallel lines along the sides of a receptacle many inches long. In the young state each grain is tipped with a long slender style as fine as a thread of silk; and many hundreds of such styles being collected together from each receptacle, the whole resemble a silken tassel hanging down from the orifice of the sheathing leaves in which the inflorescence is enwrapped. When ripe the corn is still covered by the sheathing leaves, and is only to be discovered when the latter are stripped back. The male or

MAIZENA

barron flowers grow in a loose panicle at the top of the stem. There are many varieties of maize; some with stems seven or eight feet high, others not exceeding the stature of two feet; some requiring a long summer to ripen their grain, others coming to perfection in a couple of months. The colour of the grain is also variable—chocolate-coloured, red, crimson, yellow, white, and variegated, are all known to the American planter. This kind of corn is not grown exclusively for the sake of the ripe grain; the young female inflorescence, which is sweet and tender, is boiled or cooked in other ways as a delicate vegetable, and the young stems are occasionally given to cattle. Many attempts have been made to cultivate maize in England as a field crop, but without success. It does not thrive north of the basin of the Mediterranean, and requires a higher summer heat than we usually experience in these islands.

Maizena. A fine flour prepared from maize or Indian corn.

Majesty (Lat. *majestas*). This title of honour is derived from the Romans, among whom it stood for the collective power and dignity of the sovereign body; as *majestas populi Romani*. Hence treason was termed *crimen læsæ majestatis*, an injury offered to majesty. Majesty was the attribute of consuls, prators, &c., only as representing the public; and hence, in later times, when it was transferred to the emperors along with the sovereign power, inferior magistrates were entitled, in ceremonial language, by the appellation of *dignitas*. Majesty is now the conventional title of European emperors and kings. (The sultan of Turkey has no more elevated title in our ceremonial than *highness*.) It appears to have been first assumed by the emperors, who represented the imperial dignity of Rome; then by the French king Henry II.; in England by Elizabeth. The emperor of Austria has the title *majesty*, with the prefix K.K. (Kaiserliche, Königliche; i.e. Imperial, Royal).

Apostolical Majesty.—A title bestowed on Stephen, duke of Hungary, about A.D. 1000, by Pope Sylvester II. Referred on the empress-queen Maria Theresa in 1758.

Catholic Majesty.—A title bestowed on Ferdinand and Isabella of Spain by Pope Alexander VI. in 1491, in memory of the conquest of the Moors. It had, however, been borne by earlier Spanish monarchs.

Most Christian Majesty.—A title borne by the kings of France; first solemnly conferred on Louis XI. in 1469 by Pope Paul II.

Most Faithful Majesty.—The title of the kings of Portugal; bestowed by Benedict XIV. on John V.

Majolica Ware. A peculiar kind of pottery originally made in the island of Majorca during the occupation of the Mediterranean islands by the Moors. It consisted of a body formed of common earthenware, which was heightened with colour, and received usually a lead glaze. Mr. Minton has lately revived the taste for a ware very similar to that of Majorca;

MAJORAT

his productions are, however, of much purer taste than the models which he followed.

Major (Lat. *greater*). In the Army, a field officer next in rank above captain, and immediately inferior to a lieutenant-colonel. His chief duties consist in superintending the exercises of his regiment or battalion, and of putting in execution the commands of his superior officer. This class of field officers did not exist till the beginning of the seventeenth century. The prices of a major's commission in the British army are as follow: In the cavalry and infantry of the line, 3,200*l.*; in the life and royal horse guards, with the rank of lieutenant-colonel, 6,350*l.* The daily pay is, in the life and horse guards, 1*l.* 4*s.* 5*d.*; in the foot guards, 1*l.* 3*s.*; cavalry, 19*s.* 3*d.*; infantry, 16*s.* The regimental rank of major does not exist either in the artillery, engineers, or marines. The major of brigade is a staff officer, who performs for a brigade, or in a garrison, duties equivalent to those of an officer of the adjutant-general's department. *Major-general* is an officer next in rank below a lieutenant-general.

Major Domo (Lat. *major domus, greater officer of the house*). In the courts of those kingdoms which were formed out of the fragments of the Western Empire, three different offices seem to be designated by this title: 1. The *maitre d'hotel*, or chief officer of the prince's table, *prefectus mensæ, architrictinus, dapifer, &c.*; 2. The mayor of the palace (*œconomus, steward*); 3. The first minister, prefect of the palace, count of the palace, &c. Charles Martel is termed *major domus* by some ancient historians. This title became in later times confounded with that of *seneschal*. In Germany, under the Otthos and the house of Swabia, the *dapifer* was an officer of high rank, who bore, amongst other duties, the standard of his sovereign. The count palatine was *dapifer* of the empire; the elector of Bavaria, *arch-dapifer*. In England he was a personage of less distinction, and his subscription generally appears last among the attesting witnesses to ancient charters.

Major and Minor. In Music, terms applied to imperfect concords differing from each other by a semitone minor. For Major and Minor Keys, see KEY.

Major Term. In Logic, in a syllogism, the predicate of the conclusion. The major premiss is that which contains the major term. In hypothetical syllogisms, the hypothetical premiss is called the major.

Majorat (Fr.). In modern legal phraseology, as employed by several Continental nations, the right of succession to property according to age. It is defined 'a *fidei commissum* gradual, successive, perpetual, indivisible, made with a view to preserve the name, arms, and dignity of a family, and destined for ever to the eldest member of it.' In the German empire and in Spain this species of entails is of great antiquity. [MATRAGONO.]

The German and Spanish laws of majorat had no exact equivalent in old France; but

MAJORITY

a species of majorat existed in the case of the Duché-Pairies, abolished at the Revolution, with other feudal institutions. The general rule of French law, that children succeed equally to their parents' property, is only modified by the regulations respecting what is termed a *portion disponible*. (*Code Civil*, art. 913 &c.) A person who leaves one child only can dispose, by will or donation, of half his property; one who leaves two one-third; and so on; a person who dies without descendants, but leaving 'ascendants,' one-half or three-fourths, according to certain rules; if he leaves only collaterals, he may dispose of the whole. The term *majorat* is still used in France to express the property, landed or funded, which by virtue of several decrees of the first empire might be reserved by persons enjoying hereditary titles of honour, and attached to the title so as to descend with it.

Majority. In Politics, the age at which the sovereign, in hereditary monarchies, becomes capable of exercising supreme authority. [MINORITY; REGENT.]

Majusculæ or Capitales Litteræ. In Diplomatics, capital letters. The Latin manuscripts of the classical age which we possess (those found at Pompeii, and a few parchment MSS. of very early date) are written in capital letters. Few instruments or books of a later date than the sixth century are in capital letters.

Mal de la Rosa (Span. *rose-cvîl*). A disease endemic in the Asturias, attended by redness of the skin.

Malabathrum (Lat.; Gr. *μαλαβδθρον*). The leaf of the Cassia laurel, from Malabar, *Cinnamomum malabathrum*.

Malachite (Gr. *μαλακός*, soft; hence also sometimes called *Velvet Copper-ore*). Malachite -- Green Carbonate of Copper is a *copper-stalactite* or *stalagmite* containing about 67.33 per cent. of the metal. It is common in Cornwall, and is a frequent constituent in the copper ores of South Australia, Siberia, and other countries. It seldom occurs crystallised, but generally in masses with botryoidal or reniform surfaces, and banded internally with various shades of bright green. It is in great request for ornamental purposes on account of the beauty of its colour, the variety of its markings, and the high degree of polish which it may be made to receive.

Malacia (Gr. *μαλακία*, weakness). A depraved appetite.

Malacoderms (Gr. *μαλακός*, and *δέρμα*, skin). The name of a tribe of Serricorn beetles, including those with a soft and flexible body.

Malacolite (Gr. *μαλακός*, and *λίθος*, stone). A variety of Augite of a dark-green colour. [SARLITE.]

Malacology (Gr. *μαλάνη*, the Aristotelian name of the Mollusca of the moderns). The science of the MOLLUSCS [see that word for their general characters]. Cuvier, the great reviver of this branch of natural history, divided the Molluscs into six classes:—

MALACOLOGY

- I. *Cephalopoda*.—Mantle in form of a sac, open anteriorly, containing the branchiæ and abdominal viscera; head protruding from the mantle, well developed, and crowned by fleshy productions, by means of which they crawl and seize various objects.
- II. *Pteropoda*.—Mantle closed; appendages of the head either wanting or extremely reduced. The principal organs of locomotion are two membranous fins, like wings, situated on the sides of the neck.
- III. *Gastropoda*.—These crawl by means of a fleshy disc on their belly. The mouth is supported by a head.
- IV. *Acéphala*.—The mantle encloses the branchiæ and viscera; the mouth opens within its cavity, and is not supported by a distinct head. The mantle may be open throughout its length, at both ends, or at one extremity only.
- V. *Brachiopoda*.—These are also enclosed in a mantle without an apparent head; but have a pair of long, fleshy, ciliated arms, which are spiral when retracted.
- VI. *Cirrhopoda*.—This class Cuvier defines as being similar to the other Molluscs in the mantle, branchiæ, &c.; but as differing from them in having numerous horny and articulated limbs, and a nervous system more nearly resembling that of the Articulata.

Since the early form and metamorphoses of the *Cirrhopoda*, or, more properly, *Cirripedia*, were known, most zoologists have regarded them as members of the Articulata sub-kingdom.

The classification of the Mollusca has been much perfected by those zoologists who have been attracted to the study of this department of the animal kingdom by the beautiful and diversified coverings of the testaceous species. Among these Lamarck ranks deservedly the chief; and his system has long guided the conchologist in the arrangement of his shells.

In the system of Lamarck, the natural primary group of animals to which the science of malacology relates constitutes the 11th and 12th classes of his Invertebrata. The first of these classes, under the name of *Conchifera*, is equivalent to the Testaceous *Acéphala* and *Brachiopoda* of Cuvier; and these low-organised headless Mollusca have their external shelly defensive covering rendered the more complete by way of compensation for the slight development of the nervous centres to which the impressions of external objects are referred, and from which the acts of volition emanate. Instead of one shell, they are therefore provided with and generally completely covered by two shells, which are technically called *valves*; and the *Conchifera* of Lamarck thus include the Molluscs with bivalve shells. These are divided into two orders, *Dimyaria* and *Monomyaria*.

The following classification, by the late Dr. Woodward, is now generally adopted, and

MALACOLOGY

has entirely superseded the Lamarckian system:—

CEPHALOPODA.

DISBRANCHIATA.

Argonautidae.—Argonauta, *Linnaeus*.

Teuthidae.—Loligo, *Lamarck*. Sepioteuthis, *Blainville*. Beloteuthis, *Münster* (Teudopsis, *Deslongchamps*). Geoteuthis, *Münster*. Lepoteuthis, *Meyer*. Cranchia, *Leach*, 1817. Sepioida, *Leach*, 1817 (Rossia, *Owen*). Loligopsis, *Lamarck*, 1811. Cheiroteuthis, *D'Orbigny*. Histiotenuthis, *D'Orbigny*. Onychoteuthis, *Lichtenstein*. Enoplateuthis, *D'Orbigny*. Ommastrephes, *D'Orbigny*.

Belemnitidae.—Belemnites, *Lamarck*, 1801. Belemnites, *D'Orbigny*. Acanthoteuthis, *Münster*. Conoteuthis, *D'Orbigny*.

Sepiidae.—Sepia, *Linnaeus* (Coccoteuthis, *Owen*). Spirulirostra, *D'Orbigny*. Beloptera, *Deshayes*. Belemnosis, *Edwards*. Helicurus, *Dana*.

Spirulidae.—Spirula, *Lamarck*.

TETRABRANCHIATA.

Nautilidae.—Nautilus, *Breynius*, 1732 (Aturia, *Bronn*). Discites, *M'Coy*. Trigonoceras, *M'Coy*. Temnocheilus, *M'Coy*. Cryptoceras, *D'Orbigny*. Lituities, *Breynius*. Trochoceras, *Barrande*, 1848. Clymenia, *Münster*, 1832.

Orthoceratidae.—Orthoceras, *Breynius* (Cameroeras, *Conrad*. Endoceras, *Hall*. Tretoeras, *Salter*. Huronia, *Stokes*). Actinoceras, *Stokes* (Hormoceras, *Stokes*). Discosorus, *Hall*. Apioceras, *Fischer*. Gomphoceras, *J. Sowerby*, 1839. Phragmoceras, *Broderip*. Cytoeras, *Goldfuss*, 1833. Gyroceras, *D'Orbigny*. Ascoeras, *Barrande*, 1848.

Ammonitidae.—Goniates, *De Haan*. Ceratites, *De Haan*. Ammonites, *Bruguière*. Crioceras, *Leveillé*. Toxoceras, *D'Orbigny*. Anycloceras, *D'Orbigny*. Scaphites, *Parkinson*. Helicoceras, *D'Orbigny*. Turritiles, *Lamarck*. Hamites, *Parkinson*. Ptychoceras, *D'Orbigny*. Baculites, *Lamarck*.

GASTEROPODA.

PROTINBRANCHIATA, Cuvier.

(Siphonostomata.)

Strombidae.—Strombus, *Linnaeus*. Pteroceras, *Lamarck*. Rostellaria, *Lamarck* (Spinigera, *D'Orbigny*, 1847). Seraphs, *Montfort*.

Muricidae.—Murex, *Linnaeus* (Typhis, *Montfort*. Trophon, *Montfort*). Pisania, *Bivon*, 1832. Columbella, *Lamarck*. Columbella, *D'Orbigny*. Fasciolaria, *Lamarck*. Mitra, *Lamarck* (Imbricaria, *Schumacher*. Cyclindra, *Schumacher*. Hyalina, *Schumacher*. Turbinella, *Lamarck* (Cynodonta, *Schumacher*. Lætitus, *Montfort*. Lagna, *Schumacher*). Fusus, *Lamarck* (Clavella, *Swainson*. Fulgur, *Montfort*. Myristica, *Swainson*. Fusioneella, *Gray*. Chrysodomus, *Swainson*).

Buccinidae.—Buccinum, *Linnaeus*. Pseudoliva, *Swainson*. Anolax, *Conrad*. Halia, *Risso*. Eburna, *Lamarck*. Nassa, *Lamarck* (Cylleus, *Gray*. Northia, *Gray*. Cyclonassa, *Swainson*).

Phos, Montfort. Purpura, *Lamarck* (Concholepas, *Favan*. Cuma, *Humphrey*. Rapana, *Schumacher*). Monoceras, *Lamarck*. Purpurina, *D'Orbigny*. Amberlyra, *Morris and Lyett*. Ricinula, *Lamarck*. Magilus, *Montfort* (Lep-toconchus, *Rüppel*). Harpa, *Lamarck*. Oliva, *Lamarck* (Olivella, *Swainson*. Scaphula, *Swainson*. Agaronia, *Gray*). Ancillaria, *Lamarck*.

Cassididae.—Cassis, *Lamarck*. Oniscia, *Sowerby*. Dolium, *Lamarck* (Males, *Valenciennes*). Cassidaria, *Lamarck*. Triton, *Lamarck*. Nassaria, *Pfeiffer*. Ranella, *Lamarck*. Pyrus, *Lamarck*.

Conidae.—Conus, *Linnaeus* (Conorbis, *Swainson*). Pleurotoma, *Lamarck* (Drillia, *Gray*. Clavatulæ, *Lamarck*. Cithara, *Schumacher*. Tomella, *Swainson*. Borsonia, *Béllardi*. Clionella, *Gray*. Mangelia, *Leach*. Bela, *Leach*. Defrancia, *Millet*. Daphnella, *Hinds*). Lachesis, *Risso*. Terebra, *Lamarck*.

Volutidae.—Voluta, *Linnaeus* (Volutilithes, *Swainson*. Scaphella, *Swainson*. Volutomitra, *Gray*. Melo, *Broderip*). Cymba, *Broderip*. Marginella, *Lamarck*.

Cypræidae.—Cypræa, *Linnaeus* (Cyprovalva, *Gray*. Luponia, *Gray*. Trivia, *Gray*). ? Pachybatron, *Gaskoin*. Erato, *Risso*. Ovulum, *Lamarck* (Volva, *Fleming*. Radius, *Montfort*).

HOLOSTOMATA.

Naticidae.—Natica, *Lamarck* (Naticopsis, *M'Coy*. Euspira, *Agassiz*. Neverita, *Risso*. Lunatia, *Gray*. Globulus, *J. Sowerby*. Deshayesia, *Raulin*. Polinices, *Montfort*. Cernina, *Gray*). Sigaretus, *Lamarck* (Naticina, *Gray*). Lamellaria, *Montagu* (Oncidiopsis, *Beck*. Mursenina, *Loven*). Velutina, *Fleming*.

Cancellariidae.—Cancellaria, *Lamarck* (Admete, *Philippi*). Trichotropis, *Broderip*. ? Cerithiopsis, *Forbes and Hanley*. ? Separatista, *Gray*.

Pyramidellidae.—Pyramidella, *Lamarck*. Odostomia, *Fleming*. Aclis, *Loven*. Chemnitzia, *D'Orbigny*. Loxonema, *Philips*. Macrocheilus, *Phillips*. Eulimella, *Forbes*. Monopigma, *Lea*. ? Chilostoma, *Deshayes*. Eulima, *Risso* (Niso, *Risso*). Styliina, *Fleming*.

Solariidae.—Solarium, *Lamarck* (Philippia, *Gray*. Torinia, *Gray*. Bifrontia, *Deshayes*). Discohelix, *Dunker*. Platysoma, *Hörnes*.

Scalariidae.—Scalaria, *Lamarck*.

Cerithiidae.—Cerithium, *Bruguière* (Rhynchoceras, *Swainson*. Bittium, *Leach*). ? Ceritella, *Morris and Lyett*. ? Brachytrema, *Morris and Lyett*. Triforis, *Deshayes*. Potamides, *Brongniart* (Vicarya, *D'Archiac*. Cerithidea, *Swainson*. Terebralia, *Swainson*. Pyrazus, *Montfort*. Lampania, *Gray*). Diastoma, *Deshayes*. Fastigiella, *Reeve*. Planaxia, *Lamarck* (Quoyia, *Deshayes*). Nerinea, *DeFrance*. Aporthais, *Aldrovandus*. Alaria, *Morris and Lyett*. Struthiolaria, *Lamarck*.

Turritellidae.—Turritella, *Lamarck*. Proto, *DeFrance*. Holopella, *M'Coy*. Mesalia, *Gray*. ? Scolostoma, *Braun*. Cæcum, *Fleming*. Vermetus, *Adanson* (Petalocochus, *Lea*. Serpulorbis, *Sassi*). Siliquaria, *Bruguière*.

MALACOLOGY

Melaniada.—*Melania*, Lamarck (Melanatria, Bowedick. Vibex, Oken. Cerphasias, Swainson. Hemisimus, Swainson. Melafusus, Swainson. Melatoma, Anthony. Anculotus, Say. Amnicola, Gould and Huxley). Paludomus, Swainson. Tanalia, Gray. Melanopsis, Lamarck. Pirena, Lamarck.

Paludinidae.—*Paludina*, Lamarck. Bithinia, Gray. Valvata, Müller. Ampullaria, Lamarck (Pomus, Humphrey. Marisa, Gray. Asolene, D'Orbigny). Lanistes, Montfort. Meladomus, Swainson. ? *Amphibola*, Schumacher.

Litorinidae.—*Litorina*, Férussac (Tectaria, Cuvier. Modulux, Gray. Risella, Gray). Narica, Reclus (Naticella, Münster). Fossarus, Philippi. Lacuna, Turton. Litiops, Rang. ? *Chelotropis*, Forbes. ? *Macgillivrayia*, Forbes. Rissos, Frémenville (Rissoina, D'Orbigny). ? *Jeffreysia*, Alder (Skenea, Fleming. Hydrobia, Hartmann). Paludestrina, D'Orbigny. Lithoglyphus, Muhlfeldt. Nematura, Benson. Syncera, Gray. Truncatella, Risso.

Calyptræidae.—*Calyptræa*, Lamarck (Crucibulum, Schumacher. Trochita, Schumacher). Crepidula, Lamarck. Fileopsis, Lamarck (Amathina, Gray). Metoptoma, Phillips. Platyceras, Conrad. Hipponyx, DeFrance (Amalthea, Schumacher). ? *Phorus*, Montfort.

Turbinidae.—*Turbo*, Linnaeus. Phasianella, Lamarck. Imperator, Montfort. Trochus, Linnaeus (Pyramis, Chemnitz. Gibbula, Leach. Margarita, Leach). Elenchus, Humphrey (Bankivia, Muhlfeldt). Rotella, Lamarck. Monodonta, Lamarck. Delphinula, Lamarck (Liotia, Gray. Collonia, Gray). Cyclostrema, Marryat (Adeorbis, S. Wood. Vitrinella, C. B. Adams). Euomphalus, Sowerby. Ophileta, Vanuxem. Phanerotinus, J. Sowerby. Stomatella, Lamarck. Gena, Gray. Broderipia, Gray.

Haliotidae.—*Haliotia*, Linnaeus. Stomatia, Lamarck. Scissurella, D'Orbigny. Pleurotomaria, DeFrance. Catantostoma, Sandberger. Murchisonia, D'Archiac. Trochotoma, Lycett. Cirrus, Sowerby.

Ianthinidae.—*Ianthina*, Lamarck. Rhapsistoma, Hall. Scalites, Conrad. Holopea, Hall. ? *Recluzia*, Pettit.

Fissurellidae.—*Fissurella*, Lamarck (Pupillia, Gray. Fissurellidæa, D'Orbigny. Lucapina, Gray). Macrochisma, Swainson. Puncturella, Lowe. Rimula, DeFrance. Emarginula, Lamarck (Hemitoma, Swainson). Deslongchampsia, M' Coy. Parmophorus, Blainville.

Neritidae.—*Nerita*, Linnaeus. Neritoma, Morris. Neritopsis, Grateloup. Velates, Montfort. Pileolus, J. Sowerby. Neritina, Lamarck. Navicella, Lamarck.

SCUTIBRANCHIATA.

Patellidae.—*Patella*, Linnaeus (Nacella, Schumacher. Scutellina, Gray). Acmaea, Eschscholtz, 1830 (Lepeta, Gray. Pilidium, Forbes). Gardinia, Gray. ? *Siphonaria*, Blainville.

Dentaliidae.—*Dentalium*, Linnaeus. *Chitonidae*.—*Chiton*, Linnaeus (Tonica, Gray. Acanthopleura, Guilding. Mopalia, Gray. Katharina, Gray. Cryptochiton, Gray. Acan-

thochites, Leach. Chitonellus, Lamarck). Helminthochiton, Salter.

PULMONIFERA.

(In-Operculata.)

Helicidae.—*Helix*, Linnaeus (Acavus, Montfort. Geotrochus, Hasselt. Polygyra, Say. Tridopsis, Rafinesque. Carocolla, Lamarck). Anastoma, Fischer. Streptaxis, Gray. Sagda, Beck. Helicella, Lamarck. Stenopus, Guilding (Pfeifferia, Gray). Vitrina, Draparnaud (Daudebardia, Hartmann. Simpulopsis, Beck). Succinea, Draparnaud. Omalonyx, D'Orbigny. Bulimus, Scopoli (Bulimulus, Leach. Odontostomus, Beck. Pachyotis, Beck. Gibbus, Montfort). Partula, Férussac. Achatina, Lamarck (Zua, Leach. Azeca, Leach. Tornatellina, Beck. Cionella, Hartmann). Glandina, Schumacher. Spiraxis, C. B. Adams. Achatinella, Swainson. Pupa, Lamarck (Vertigo, Müller). Cylandrella, Pfeiffer. Bales, Prideaux. Megaspira, Lea. Clausilia, Draparnaud.

Limacidae.—*Limax*, Linnaeus. Geomalacus, Allan. Arion, Férussac. Parmacella, Cuvier. Testacella, Cuvier.

Limnæidae.—*Limnæa*, Lamarck. Amphipeplea, Nilsson. Chilinia, Gray. Physa, Draparnaud (Physopsis, Kraus. Camptoceras, Benson). ? *Camptonyx*, Benson. Ancylus, Geoffroy (Vellatia, Gray). ? *Latia*, Gray. Gundlachia, Pfeiffer. Planorbis, Müller (Planorbula, Haldemann).

Auriculidae.—*Auricula*, Lamarck (Polydonta, Fischer. Melampus, Montfort. Conovulus, Lamarck). Pedipes, Adanson. Otina, Alder. Carychium, Müller.

Operculata.

Cyclostomidae.—*Cyclostoma*, Lamarck (Otopoma, Gray. Choanopoma, Pfeiffer. Cistula, Gray. Realia, Gray. Pomatias, Stüder). Ferrussina, Grateloup. Cyclophorus, Montfort (Pterocyclos, Benson. Aulopoma, Troschel. Opisthoporus, Benson. Cyclostus, Guilding. Leptopoma, Pfeiffer. Megalostoma, Guilding. Craspedopoma, Pfeiffer. Cataulus, Pfeiffer). Rhabdulus, Benson. Diplomatina, Benson (Paxillus, H. and A. Adams). Pupina, Vignard (Rhegostoma, Hasselt. Callia, Gray. Pupinella, Gray).

Helicinidae.—*Helicina*, Lamarck (Lucidella, Gray. Trochatella, Swainson. Alcadie, Gray). Proserpina, Guilding. Stoastoma, C. B. Adams.

Aciculidae.—*Acicula*, Hartmann. Geomelania, Pfeiffer.

TECTIBRANCHIATA.

Tornatellidae.—*Tornatella*, Lamarck (Cylindrites, Lycett. Acteonina, D'Orbigny. Acteonella, D'Orbigny). Cinulia, Gray. Ringicula, Deshayes. Globiconcha, D'Orbigny. Varigera, D'Orbigny. ? *Tylostoma*, Sharp. Pterodonta, D'Orbigny. Tornatina, A. Adams. ? *Volvula*, A. Adams. ? *Volvaria*, Lamarck.

Bullidae.—*Bulla*, Lamarck (Cryptopthalmus, Ehrenberg. Phaneroptthalmus, A. Adams. Smaragdina, A. Adams. Acera, Müller. Cylichna, Lovén. Amphispheya, Lovén. Aplustrum,

MALACOLOGY

Solamacher). *Scaphander*, *Montfort*. *Philine*, *Adamus*, 1772 (*Chefidonax*, *A. Adams*).

Aplysida.—*Aplysia*, *Gmelin* (*Aclecia*, *Rang*). *Dolabella*, *Lamarck*. *Icarus*, *Forbes*, 1843. *Lobiger*, *Krohn*.

Pluteobranchiida.—*Pluteobranchius*, *Cuvier*. *Umbrella*, *Chemnitz*. *Tylodina*, *Rafinesque*.

NUCULOBRANCHIATA.

Ferolida.—*Carinaria*, *Lamarck*. *Cardiopoda*, *D'Orbigny*.

Atlantida.—*Atlanta*, *Lesueur*. *Oxygyrus*, *Benson*. ? *Calcarella*, *Souleyet*. *Porcellia*, *Lévis*. *Bellerophon*, *Montfort*. *Bellerophina*, *D'Orbigny*. *Cyrtolites*, *Conrad*. *Ecculiomphalus*, *Portlock*. ? *Machurea*, *Lesueur*.

PTEROPODA.

(*Aporobranchiata*.)

TENOOSOMATA.

Hyaleida.—*Hyalea*, *Lamarck*. *Cleodora*, *Peron and Lesueur*. *Oressia*, *Rang*. *Cuvieria*, *Rang*. *Vaginella*, *Daudin*. *Theca*, *Morris*, 1846. *Pterotheca*, *Salter*. *Conularia*, *Müller* (*Coleoprion*, *Sandberger*). *Cymbula*, *Peron and Lesueur*.

Limacinaida.—*Limacina*, *Cuvier*. *Spiralis*, *Eydoux and Souleyet*.

SRACHIOPODA, *Cuvier*, 1805.

PALLIOBRANCHIATA.

Terebratulida.—*Terebratula*, *Bruguière* (*Terebratulina*, *D'Orbigny*. *Waldheimia*, *King*). *Terebratella*, *D'Orbigny* (*Trigonosemus*, *König*). *Lyræ*, *Cumberland*, 1816. *Magas*, *Sowerby*. *Bouchardia*, *Davidson*. *Martina*, *Davidson*. *Kraussia*, *Davidson*. *Megerlia*, *King*. *Argiope*, *DuRoi*. *Thesidia*, *D'Orbigny*. *Stringocephalus*, *D'Orbigny*.

Sowerby (*Spiriferina*, *D'Orbigny*). *Cyrtia*, *Dalman* (*Cyrtina*, *Davidson*). *Athyria*, *M'Coy* (*Merista*, *Suess*). *Retzia*, *Uncites*, *D'Orbigny*.

Aynonellida.—*Rhynchonella*, *Fischer* (? *Foraminites*, *Pander*. *Camarophoria*, *King*). *Pentamerus*, *Sowerby*. *Atrypa*, *Dalman*.

Orthisida.—*Orthis*, *Dalman* (*Orthisina*, *D'Orbigny*). *Strophomena*, *Blainville* (*Leptæna*, *Dalman*. *Konnickia*, *Suess*). *Davidsonia*, *Bouchard*. *Calceola*, *Lamarck*.

Productida.—*Producta*, *Sowerby* (*Aulostegæ*, *Helmarson*. *Strophalonia*, *King*). *Chonetes*, *Fischer*.

Craniida.—*Crania*, *Retzius*. *Dicrinida*.—*Dicrina*, *Lamarck* (*Trematis*, *Sharpe*). *Siphonotreta*, *Vernouil*. *Acrotreta*, *Kutorga*.

Lingulida.—*Lingula*, *Bruguière*. *Obolus*, *Richard*.

CONCHIFERA.

BRANCHIATA.

(*Asiphonida*.)

Ostroida.—*Ostrea*, *Linnaeus*. *Gryphæa*, *Lamarck*. *Exogyra*, *Sowerby*.

Anomida.—*Anomia*, *Linnaeus*. *Broderip*. *Limnobia*, *Broderip*.

Solenaster (*Carolla*, *Cantraine*, 1835. *Placynopsis*, *Morris and Lycett*).

Pectinida.—*Pecten*, *Müller* (*Neithus*, *Broun*. *Pallium*, *Schumacher*. *Hinnites*, *D'Orbigny*. *Hemipecten*, *A. Adams*). *Lima*, *Bruguière* (*Limatula*, *S. Wood*. *Limes*, *Broun*). *Spondylus*, *Linnaeus* (*Pedum*, *Bruguière*). *Plicatula*, *Lamarck*.

Aviculida.—*Avicula*, *Bruguière* (*Meleagrina*, *Lamarck*. *Malleus*, *Lamarck*). *Vulsella*, *Lamarck*. *Pteroperna*, *Lycett*, 1852. *Amboynichia*, *Hall*, 1847. ? *Cardiola*, *Broderip*, 1844. ? *Eurydesma*, *Morris*. *Pterinea*, *Goldfuss*, 1832. *Monotis*, *Broun*, 1830. *Posidonomya*, *Broun*. *Aviclo-pecten*, *M'Coy*, 1852. *Gervillia*, *D'Orbigny* (*Bakewellia*, *King*). *Perna*, *Bruguière*. *Crenatula*, *Lamarck*. *Hypotrema*, *D'Orbigny*, 1853. *Inoceramus*, *Sowerby*, 1814. *Pinna*, *Linnaeus* (*Trichites*, *Lycett*).

Mytilida.—*Mytilus*, *Linnaeus* (*Septifer*, *Reclus*). *Myalina*, *Koninck*, 1842. *Modiola*, *Lamarck*. *Lithodomus*, *Cuvier*. *Crenella*, *Broun*. *Modiolarca*, *Gray*. ? *Mytilimeria*, *Conrad*. *Modiolopsis*, *Hall*, 1847. *Orthonotus*, *Conrad*. ? *Goniophora*, *Phillips*. *Dreissena*, *Van Beneden*.

Arcaida.—*Arca*, *Linnaeus*. *Cacullæa*, *Lamarck* (*Macraron*, *Lycett*. *Isarca*, *Münster*). *Pectunculus*, *Lamarck*. *Limopsis*, *Sassi*, 1837 (*Nucunella*, *D'Orbigny*). *Nucula*, *Lamarck* (*Nuculina*, *D'Orbigny*. *Ctenodonta*, *Salter*. *Cacullælla*, *M'Coy*. *Leda*, *Schumacher*. *Yoldia*, *Müller*). *Solenella*, *G. Sowerby*. *Solemya*, *Lamarck*.

Trigoniada.—*Trigonia*, *Bruguière*. *Myophoria*, *Broun*, 1830. *Axinus*, *Sowerby*, 1821. *Lyrodesma*, *Conrad*, 1841. *Verticordia*, *Seares Wood*.

Unionida.—*Unio*, *Reis*. *Symphynota*, *Sowerby*. *Monocondylæa*, *D'Orbigny*. *Anodon*, *Cuvier*. *Hyria*, *Lamarck*. *Castalia*, *Lamarck*. *Iridina*, *Lamarck*. *Mycetopus*, *D'Orbigny*. *Ætheria*, *Lamarck*. *Mülleria*, *Férussac*.

SIPHONATA.

(*Integropalliata*.)

Chamida.—*Chama*, *Linnaeus*. *Monopleura*, *Matheron*. *Diceras*, *Lamarck*. *Requienia*, *Matheron*.

Hippuritida.—*Hippurites*, *Lamarck*. *Radiolites*, *Lamarck*, 1801 (*Bi-radiolites*, *D'Orbigny*). *Caprinella*, *D'Orbigny*. *Caprina*, *D'Orbigny*. *Caprotina*, *D'Orbigny*.

Sowerby*. *Hippopodium*, *Coneybeare*. *Cardita*, *Bruguère* (*Venericardia*, *Lamarck*).

SINU-PALLIATA.

Venerida.—*Venus*, *Linnaeus* (*Saxidomus*, *Conrad*). *Cytherea*, *Lamarck* (*Meroe*, *Schumacher*). *Trigona*, *Mühlfeldt*. *Grateloupia*, *Desmoulin*. *Artemis*, *Poli* (*Cyrelina*, *Deshayes*). *Clementia*, *Gray*. *Lacinopsis*, *Forbes*. *Tapes*, *Mühlfeldt*. *Venerupis*, *Lamarck*. *Petricola*, *Lamarck*. *Glaucomya*, *Gray*.

Macridæ.—*Mactra*, *Linnaeus*. *Gnathodon*, *Gray*. *Lutraria*, *Lamarck* (*Resania*, *Gray*). *Anatinella*, *G. Sowerby*.

Tellinida.—*Tellina*, *Linnaeus* (*Tellinides*, *Lamarck*). *Gastrea*, *Schumacher*. *Capsula*, *Schumacher*. *Psammodia*, *Lamarck*. *Quenstedtia*, *Morris* and *Lyceet*. *Sanguinolaria*, *Lamarck*. *Semele*, *Schumacher* (*Cumingia*, *G. Sowerby*). *Syndosmya*, *Reclus*. *Scrobicularia*, *Schumacher*. *Mesodesma*, *Deshayes* (*Anape*, *Gray*). *Ervilia*, *Turton*. *Sowerbya*, *D'Orbigny*. *Donax*, *Linnaeus* (*Amphicena*, *Philippi*). *Iphigenia*, *Schumacher*. *Galatea*, *Bruguère*.

Solenida.—*Solen*, *Linnaeus* (*Cultellus*, *Schumacher*). *Ceratisolen*, *Forbes*. *Machæra*, *Gould*. *Solecurtus*, *Blainville*. *Novaculina*, *Benson*. *Glycimeris*, *Lamarck*.

Myacida.—*Mya*, *Linnaeus*. *Corbula*, *Bruguère*. *Potamomya*, *J. Sowerby*. *Sphenia*, *Turton*. *Thetis*, *Sowerby* (*Eucharis*, *Reclus*). *Panopæa*, *Menard de la Groye*.

Anatinida.—*Anatina*, *Lamarck*. *Periploma*, *Schumacher*. *Cercomya*, *Agassiz*. *Thracia*, *Blainville*. *Pholadomya*, *G. Sowerby*. *Myacites*, *Bronn*. *Goniomya*, *Agassiz*. *Grammysia*, *Verneuil*. *Sedgwickia*, *M' Coy*. *Ceromya*, *Agassiz*. *Gresslya*, *Agassiz*. *Cardiomorpha*, *Koninck*. *Edmondia*, *Koninck*. *Lyonsia*, *Turton*, 1822. *Entodesma*, *Philippi*. *Pandora*, *Bruguère*. *Myadora*, *Gray*. *Myochama*, *Stutchbury*. *Chamostrea*, *Rossey*.

Gastrochenida.—*Gastrochena*, *Spengler*, 1783. *Chæna*, *Retz*, 1788. *Saxicava*, *Bellevue*. *Clavagella*, *Lamarck*. *Aspergillum*, *Lamarck*.

Pholadida.—*Pholas*, *Linnaeus*. *Pholadidea*, *Turton*, 1819 (*Martesia*, *Blainville*). *Jouanetia*, *Desmoulin*. *Parapholas*, *Conrad*. *Xylophaga*, *Turton*. *Teredo*, *Adanson* (*Furcella*, *Lamarck*). *Teredina*, *Lamarck*.

MALICE

Malacoe (Gr. μαλακός). A mineral having the form of Zircon, to which it is also nearly related in composition.

Malacopteri (Gr. μαλακός, and πτερόν, a feather). An order of fishes in which the endoskeleton is ossified; the exoskeleton, in most as cycloid, in a few as ganoid, scales; fins supported by rays, all save the first sometimes in the dorsal and pectoral, soft and jointed; abdominal or apodal; gills free, operculate; a swim-bladder and air-duct. To this order belong the eel, herring, salmon, pike, and carp genera.

Malacosteon (Gr. μαλακός, and στέον, a bone). A diseased softening of the bones: *mollities ossium*.

Malacostracans (Gr. μαλακός, and στροκον, a shell). The name of a division of the class Crustaceans, including those which are covered with a crust softer than the shell of the molluscs, but firmer than the covering of the Entomostracans [which see]. The term *Malacostraca* was first applied by Aristotle to the Crustacea of the moderns, being used by him in a comparative sense, as contrasted with the *Ostracoderma*, which are the modern *Testacea*.

Malagma (Gr. from μαλάσσειν, to soften). A poultice.

Malaria (Ital. *mal' aria*, bad air). The exhalation of marshy districts, which produces intermittent fevers. This term has now become of general application to deleterious emanations from decaying organic matter; but it was long restricted to emanations in that district of Italy which extends from Leghorn to Terracina in one direction, and from the sea to the Apennines in another. Even in the time of Horace, Rome was deserted two months in the year, on account of the dangers of the malaria. On the Italian malaria, see Arnold's *History of Rome*, chap. xxiii.

Malic Acid. An acid, isomeric with fumaric acid, obtained by distilling malic acid at a temperature of about 400°. It crystallises in oblique rhombic prisms, which are colourless and inodorous, but sour to the taste. They melt at 266° Fahr.

Malacotheriacæ (*Malacotherbia*, one of the genera). A small unimportant order of Violæ Exogæ, related to Passion-flowers, and found in Chili and Peru.

Malic Acid (Lat. *malum*, an apple). A peculiar acid contained in the juice of the apple and several other fruits; it may be obtained also from the berries of the *Sorbus aucuparia*, or Mountain Ash, and has hence been called *sorbic acid*. It crystallises in colourless prisms, which are sour to the taste, and soluble in water and in alcohol.

Malice (Lat. *malitia*, from *malus*, bad). In the English Law, malice does not necessarily bear the signification of particular ill-feeling towards an individual, but is a term directly importing wickedness in the commission of an act, and excluding a just cause or excuse. [*ΜΙΣΘΩΝΑ*.] Malicious injury to property is in some instances a felony, in others a misdemeanour. [Law,

MALLEABILITY

CRIMINAL.] As a general rule in criminal law, acts done wilfully are assumed to be done maliciously. (F. Stephens *On Crim. Law.*) In civil actions for injuries to which malice is essential, e.g. slander, libel, &c., the question of the existence of malice is one, in general, for the jury; but, under certain circumstances, it may be implied by the court from the absence of reasonable and probable cause, as in actions for malicious prosecution.

Malleability (Lat. *mallens, a hammer*). The property of being susceptible of extension under the blows of a hammer. It is especially characteristic of some of the metals, and in this quality gold exceeds all the others: common gold leaf is not more than a two hundred thousandth part of an inch in thickness; five grains may be thus extended so as to cover a surface of more than 270 square inches.

Malleus (Lat. *a hammer*). One of the small bones of the internal ear, attached to the *membrana tympani*, somewhat in shape resembling a hammer.

Malleus. A genus of Ostracean bivalves, characterised by having, in addition to the simple pit for the ligament, a notch on the side of the ligament for the passage of a byssus. The species of this genus are called *hammer oysters*. The most noted is the *Ostrea malleus* of Linnaeus, which has the cardinal region of the shell formed something like the head of a hammer, of which the elongated valves, extended transversely, represent the handle. It is a native of the Indian Archipelago, and still ranks among the number of rare and high-priced shells.

Mallotus. The capelan, capling, or angmareet, a small fish found in the northern hemisphere, and used as bait for cod. It is interesting as being frequently found in a fossilised state, contained in solid nodules of stone.

Mallow (Lat. *malva*). A weed common by hedgerows and waysides in Europe. It has mucilaginous properties, and has been employed in the preparation of emollient poultices, in the same way as the Marsh Mallow. Its fruit is a depressed disc, and is called by the country people *cheeses* (Fr. *fromageon*). [**MALVA.**]

Mallum. The public assembly or meeting of the people according to the usage of the old Teutonic nations. Under the Carolingian monarchs the mallum appears to have been summoned by the missus or deputy of the sovereign. There was a separate mallum for every leading state or kingdom which composed the empire; and it was attended by the notables of all the various races of inhabitants (Roman, Frankish, Gothic, &c.), and in some instances by the Scabini or Echevins, who represented the communities of the towns.

Malum Bricks. A kind of brick used in London for ornamental works, obtained by the burning of a clay containing carbonate of lime in intimate mixture with the silicate of alumina. It can be easily made by mixing the clay with a portion of chalk; but the best bricks

MALT

are obtained by the calcination of the natural marls of Essex and Suffolk; the first are of a yellow colour, the second a creamy white. They are easily cut, and on this account are used for arches with a small radius of curvature.

Malmsey (so called as having been made at Malvasia in the Morea). A strong and fine-flavoured sweet wine, made, in Madeira, of grapes which have been allowed to shrivel upon the vine; it is of a deep golden hue. It contains between 16 and 17 per cent. of alcohol.

Malpighiaceæ (Malpighia, one of the genera). An extensive natural order of hypogynous Exogens of the Sapindal alliance, distinguished by their complete (partially symmetrical) flowers, with an imbricated calyx and naked stalked petals, by their simple stigma, by their ovules hanging by cords, and by their usually convolute embryo. They are chiefly tropical, and the larger portion of them are found in South America. The *Byrsonima* are astringent, and their bark is commonly used for tanning in Brazil. The fruit of some of the *Malpighias* is eaten. *Nitraria tridentata*, another plant of the order, is considered to be the Lotus-tree of the ancients.

Malpighian. In Anatomy, this term is applied to certain parts, especially of the kidney, in allusion to the anatomist Malpighi, by whom they were discovered or first definitely described. Thus the numerous secreting tubes (*tubuli uriniferi*), where they are collected into conical bundles, form the *Malpighian cones* or *pyramids*; the more tortuous parts of the tubes, which pass towards the surface of the kidney, terminate in, or bear on small pedicles appended to their walls, flask-shaped sacculi, named *Malpighian capsules*. The arteries of the kidney, before dividing into capillaries, form, by tortuous convolutions, little balls, called *Malpighian corpuscles* or *glomerules*.

Malt (Gr. *malz*, from *malen, to grind*). This word is used to designate grain which has become sweet in consequence of incipient germination. [**DIASTASA.**] Malt forms the principal ingredient in the manufacture of beer. Three different kinds are employed: 1. pale or amber malt; 2. brown or blown malt; and 3. roasted or black malt, the fermentation of which yields beer or porter of varying depth of colour.

The manufacture of malt has been carried on for ages in countries where the climate is too cold for the growth of the vine. Beer is spoken of by Xenophon, in his history of the retreat of the Ten Thousand, and was well known to the Romans as the beverage of Northern Europe. Wheat, rye, and oats have at different times been used for malting purposes, but in modern times it is almost entirely manufactured from the various species of barley. By the statute of Elizabeth directing the reservation of a portion of the fixed incomes of corporations in corn rents, malt is selected as one of the articles the highest price of which at Michaelmas and Lady-day is to

form the estimate of the rent for the ensuing year. Malt was first made to contribute to the public revenue in England in 1697, in Scotland in 1713, and in Ireland in 1785. The present duty on malt from barley is 2s. 7d. per bushel, and from bere or bigg 2s. The quantity of malt charged with duty in the United Kingdom during the fifteen years ending 1864, averaged nearly 500,000,000 bushels; and the revenue derived from it averaged in the same period 6,000,000*l*.

The duties levied upon malt have been attacked during the last few years, both in parliament and without it, so energetically, that elections have frequently turned upon the answers given by candidates for a seat in the legislature, as to the justice and necessity of effecting a total and unconditional repeal of those duties. At present the action of those who are unfriendly to the continuance of the tax has been ineffectual, owing, it would appear, chiefly to the difficulty of suggesting an adequate substitute for so important a branch of public revenue.

It is alleged that, in addition to the vexatious interference of all excise duties with the process of manufacture, a greater loss is incurred in a tax levied on what is virtually a raw material, than the proceeds of the tax imply; that the fact of the amount collected being almost a fixed sum from year to year, suggests that it checks consumption, the increase in population not having been followed by an increased demand for ale and beer; that the malt tax discourages private brewing, and throws the manufacture of beer entirely into the hands of brewers; that the tax prevents the employment of capital on such light lands as are particularly suitable for the growth of barley, and is therefore an impediment to the development of agricultural prosperity; that malted grain is particularly serviceable for fattening cattle, and that the existence of the tax is a hindrance to the improvement of stock, by making the time in which such stock can be available for consumption unnecessarily protracted; and that generally the malt tax is an offence against the principles of free trade and the admitted canons of taxation.

In reply, it is stated that the process of malting is so simple that excise regulations are reduced to the barest supervision over the quantity manufactured, and that a very short time is interposed between the incidence of the tax and the consumption of the product; that the sum paid is certainly uniform from year to year, but that the consumption of other articles analogous to beer and ale, and substituted for them, is the real reason why the malt revenue does not grow with population; that, granting the propriety of taxing alcoholic liquida, beer and ale are, considering the alcohol they contain, the most lightly taxed of all such substances, and that the abandonment of all duties on malt would be unfair to the distiller and the wine grower, and, what is of more importance, to the consumer; that even

now private brewing may be resorted to, but that, notwithstanding the fact that the trade of a common brewer is subject to additional duties, the advantage of the public is really consulted, and that what is called *teapot brewing* is relinquished because the product is really dearer and more uncertain: that there is no reason to think that private brewing would be adopted on the abolition of the malt duty, since private baking was not resorted to on the abolition of the corn laws; that a considerable rise has taken place of late years in the price of barley, and that therefore a sufficient stimulant is supplied to the cultivation of barley-growing soils; that malted grain is not serviceable for fattening cattle, the loss of weight and nutritive power in the process of malting amounting to at least 20 per cent., and that the abolition of the duty would have no beneficial effect on the art of breeding and fattening stock; and that, lastly, all taxes are more or less against the principles of free trade, but that those taxes are to be retained for revenue purposes which are the least mischievous and the most fair in their incidence, and that such is eminently the case with the malt tax.

Barley may, by an Act of the last session, be malted for feeding purposes under certain regulations.

Maltha (Gr. and Lat.). A mineralogical term applied to *mineral pitch*; an inflammable bituminous product, probably derived from the exsiccation of mineral tar. A cement containing mineral pitch was used by the ancients for plastering their walls, and was composed of pitch, wax, plaster, and grease. Another sort, with which the Romans used to plaster the interior of their aqueducts, was made of lime incorporated with melted pitch. The various bituminous pavements which have lately come into use are similar combinations.

Malthanates. A white tallow-like mineral from Lobau.

Malva (Gr. *μάλχα*, a mallow). A genus of *Malvaceæ* abundant by waysides. The common Mallow, *M. sylvestris*, is mucilaginous; its dried flowers are used in France in the preparation of a drink called Tisane or Pisan, which is regarded as a cure for feverish colds and other ailments. This plant is the *Mauve* of the French, and from its fading flowers has been derived the name of the colour so called. *M. rotundifolia* is in some countries used as a potherb.

Malvaceæ (Malva, one of the genera). A natural order of mucilaginous Exogenous plants of the Malval alliance, with polypetalous flowers and monadelphous stamens. The species are herbs, bushes, or trees, and are found all over the temperate and tropical part of the world, especially the latter. Their flowers are in many cases large and handsome; but the order is chiefly interesting from containing the *Gossypium* or Cotton-plant. Another species is the Marsh Mallow, *Althæa officinalis*. Some yield a fibre fit for manufacture into cordage. *Al-*

MAMELUKE

biacus cannabinus yields Indian Hemp; and *Portium elatum* furnishes Cuba Bast.

Mameluke (Arab. memalik, a slave). A name applied to the male slaves imported from Circassia into Egypt by the master of that country. In the thirteenth century, when the countries in the vicinity of Mount Caucasus were ravaged by Gengis Khan, Nojmedden, sultan of Egypt, purchased several thousands of the natives of those regions, especially Turks, and formed them into an armed body of guards. These guards or Mamelukes, in the sequel, seized on all the power of the country, murdered the sultan Touran Shah, A. D. 1258, and made Ibeg, one of their own number, his successor. After that period the Mamelukes, whose numbers were continually increased by importations from their own country, governed Egypt 263 years. (Gibbon, ch. lix.) This military sovereignty was destroyed by Selim I., the Turkish sultan who took Cairo in 1517. Nevertheless, the Mamelukes, under their twenty-four beys, continued for 200 years more to exercise a power scarcely inferior to that of the Turkish pachas, whom, in the eighteenth century, they reduced to mere ciphers in the government. Their power was again considerably broken by the French invasion under Bonaparte, to whom they offered a determined opposition. After the abandonment of Egypt by the French, the struggle between the beys and the pachas was renewed: finally, in 1811, the pacha, Mohammed Ali, having invited the principal leaders of the Mamelukes to a banquet, slew 470 of them by treachery, and compelled the remainder to submission.

Mammalia (Lat. mamma, a teat). The most highly organised class of animals, at the head of the great scale of organised nature. They possess mammary glands, and suckle their young; the fœtus is developed in the womb. Their external distinguishing marks are a covering of hair, and teats or nipples; but to the manifestation of these two characters, there are a few exceptions. The principal anatomical character is the condition of the lungs, which are suspended freely in a thoracic cavity, separated by a perfect diaphragm from the abdomen. The entire tissue of the lungs is occupied by extremely minute air-cells, with highly vascular parietes, so that the air inspired is rapidly changed, and breathing can be safely suspended only for a short time. The whole mass of circulating blood is transmitted to the lungs by the mechanism of a pulmonary auricle and ventricle, equally perfect, and inferior only in power to the systemic auricle and ventricle, which subsequently propel the aerated blood to the general system; the heart consequently consists of four distinct cavities.

The upper jaw of the Mammalia is fixed; the two rami of the lower jaw consist each of a single bony piece, and are articulated by a convex or flat condyle to the base of the zygomatic process, and not the tympanic element of the temporal bone. With a few exceptions the jaws of the Mammalia are armed with teeth:

MAMMALIA

these are arranged in a single row, are 1 in sockets sometimes by two or more fangs, and are never ankylosed to the substance of the jaw. A deciduous tooth is never succeeded by more than one corresponding tooth in the vertical direction. The tongue is fleshy, well developed, with the apex more or less free. The posterior openings of the nasal passages are protected by the *soft palate*, and the larynx, or opening of the wind-pipe, by an *epiglottis*. The alimentary canal varies with the nature of the food, but the *cæcum coli* is usually single. The rectum commonly terminates by a distinct aperture behind the urinary and generative orifices.

The bodies of the vertebræ have their articular surfaces more or less flattened, and always joined together by a series of concentric ligaments with interposed glairy fluid. The cervical vertebræ, with one or two exceptions, are seven in number. The atlas is articulated by two surfaces to two occipital condyles, developed from the ex-occipital elements. With two exceptions in the Monotremata the coracoid bone appears as a small process or appendage of the scapula. The sternum is narrow, and consists of a simple longitudinal series of bones.

The second, or distal bone, called *squamosal*, in the bat continued backwards from the maxillary arch, is not only expanded, but is applied to the side wall of the cranium, and develops the articular surface for the mandible, which surface is either concave or flat. The presphenoid is developed from a centre distinct from the basisphenoid.

The brain presents its highest state of development in the Mammalia: it consists of a cerebrum, which is generally more or less convoluted, a cerebellum with lateral lobes, and a medulla oblongata with a distinct *tuber annulare*. The optic lobes are solid, divided by a transverse fissure, and hence called *bigeminal bodies*: they are situated on the upper part of the crura cerebri, and are generally concealed by the overlapping posterior cerebral lobes. The rudiment of the *corpus callosum*, or great cerebral commissure, first begins to be distinctly recognisable in the highest Lyencephale Mammalia; and in a state of normal development, or where it bears a direct proportion to the size of the corpora striata or hemispheres of the brain, it is peculiar to the Lissencephale, Gyrencephale, and Archencephale Mammalia.

The eyes of the Mammalia are never complicated with a pecten or marsupium, a choroid gland, or sclerotic bony plates.

The organ of hearing acquires in the Mammalia a fully developed cochlea with a *lamina spiralis*: there are three distinct ossicles in the tympanum; the drum, or membrana tympani, is usually concave towards the meatus, which generally commences with a more or less complicated external ear, supported by a distinct fibro-cartilage.

The Mammalia, without exception, bring forth their young alive; hence they were termed by Aristotle *Zoœcoa*. This phenomenon is,

MAMMALIA

however, by no means peculiar to the present class; but it was supposed that they differed from other viviparous animals, as the viper, in the development of the germ by means of a placenta. Such, however, is not the case with the marsupial animals, and probably not with the Monotremes; and as the absence of the placenta is associated with several important modifications of structure in the species so developed, by which they approximate to the characters of the oviparous classes, the class Mammalia was primarily divided into two great divisions, called *Placentalia* and *Implacentalia*.

Before, however, the subdivisions are more especially characterised, it may be advantageous to trace the principal steps by which the present views of the affinities and classification of the Mammalia have been acquired.

Aristotle, choosing the locomotive system as a base, divided his *Zootoca*, the equivalent of the Linnæan mammalia, according to the nature of their locomotive organs, into three sections: 1. *Dipoda*, or bipeds; 2. *Tetrapoda*, or quadrupeds; and 3. *Apoda*, or impeds. Man is cited as the type of the first, and the whale tribe is included in the last of these primary groups; the second embraces all the rest of the class, which, in common language, are called *quadrupeds*. These Aristotle subdivided into two great natural groups, according to the modifications of the organs of touch. In the first a part of the digits is left free for the exercise of the tactile faculty, the nail or claw being placed upon one side only; in the second group the extremities of the digits are enclosed in hoofs.

These again are subdivided, the first group, or *Unguiculata* of modern mammalogists, into: 1. Those which have the front teeth trenchant, and the back teeth flattened, as the *Pithecoidea* or apes, and the *Dermaptera* or bats; 2. Those with acuminate trenchant or carnivorous teeth, which Aristotle calls *Karcharodonta*; 3. The Rodent quadrupeds, which are indicated by a negative dental character. With respect to the hoofed or *ungulate* quadrupeds, Aristotle points out subordinate groups, and characterises them by modifications of the feet. Thus, the first are the *Polyschida* or multungulate quadrupeds, as the elephant; the second are the *Dischida* or bisulcate quadrupeds, as the Ruminants and hog; the third are the *Aschida* or solidungulate quadrupeds, as the horse and ass.

Ray, with a less philosophical appreciation of the extent and nature of the class *Zootoca* or Mammalia, arranges his equivalent group of 'Viviparous four-footed animals' chiefly on the Aristotelian characters, the primary divisions being the *Unguiculata* and *Ungulata*, and the subdivisions being based on locomotive and dental characters. The whales are excluded.

Linnaeus, restoring the class Mammalia to its Aristotelian integrity, primarily subdivides it into *Unguiculata*, *Ungulata*, and *Mutica*, the latter being the equivalent of the *Apoda* of Aristotle; but his secondary divisions or orders

are taken chiefly from modifications of the dentary system. The following is the scheme of his arrangement:—

<i>Mammalia.</i>		
<i>Unguiculate</i>	Front teeth, none in either jaw	<i>Bruta.</i>
	Front teeth, cutters 2, lan- aries 0	<i>Glires.</i>
	Front teeth, cutters 4, lan- aries 1	<i>Primates.</i>
	Front teeth, piercers (6, 2, 10), lanaries 1	<i>Fera.</i>
<i>Ungulate</i>	Front teeth, in both upper and lower jaw	<i>Bellua.</i>
	Front teeth, none in the upper jaw	<i>Pecora.</i>
<i>Muticæ.</i>	Teeth variable	<i>Cete.</i>

(From the *Systema Naturæ*, ed. 16, Holmii, p. 24.)

Linnaeus defines the class Mammalia as follows: *Heart* with two auricles and two ventricles; blood warm; *lungs* respiring reciprocally (*pulmones respirantes reciproce*); *jaws* incumbent, covered, armed with teeth in most; *penis* *intrans*; generation viviparous, lactiferous; *senses*, tongue, nostrils, eyes, ears, tactile papillæ; *covering*, hairs few in tropical, very sparing in aquatic mammals; *support*, four feet, except in those which are entirely aquatic, in which the posterior feet are bound together in the fin of the tail; a *tail* in most.

Cuvier, adopting the same threefold primary division of the class, subdivides it into better and more naturally defined orders, according to various characters derived from the dental, the osseous, generative, and the locomotive systems. In giving the outline of this method, Cuvier develops the principles on which his divisions are founded.

'The characters by which Mammalia differ most essentially one from another are derived from the organs of touch, from which results their degree of dexterity; and from the organs of mastication, which determine the nature of their food; and upon these very closely depends not only everything which is connected with the digestive functions, but a variety of other circumstances relative even to their degrees of intelligence.

'The perfection of the organs of touch is estimated by the number and mobility of the digits, and the extent to which they are enclosed in a claw or in a hoof. A hoof which completely encloses that part of the digit which touches the ground precludes the exercise of it as an organ of touch or of prehension. The opposite extreme is where the nail, in the form of a simple lamina, covers only one side of the end of the digit, leaving the other side in possession of all its delicacy of tact.

'The kind of food is indicated by the molar teeth, to the form of which the articulation of the jaws invariably corresponds.

'For cutting flesh, the molar teeth must be trenchant and serrated; and the jaws fitted together, so as to move like the blades of a pair of scissors, simply opening and closing in the vertical direction.

'For bruising grains and roots, the molar teeth must have flattened crowns, and the jaws

MAMMALIA

a horizontal motion; and further, that the grinding surface may be always unequal, like a millstone, the teeth must be composed of substances of different degrees of density, and consequently wearing down in different proportions.

'The ungulate quadrupeds are all of necessity herbivorous, or with flat-crowned molars, because the conformation of their feet does not permit them to seize living prey.

'The unguiculate animals are susceptible of more variety. They are not limited to one kind of food; and besides the consequent variation in the form of their molars, they differ materially from each other in the mobility and sensibility of their digits. There is, moreover, a characteristic which prodigiously influences their dexterity, and gives variety to their modes of action: it is the faculty of opposing a thumb to the other fingers, so as to seize the smallest objects, which constitutes a *hand*, properly so called. This faculty is carried to its highest degree of perfection in man, in whom the whole anterior extremity is free, and can be exclusively employed in prehension. These different combinations, which strictly determine the nature of the several mammiferous animals, have formed the grounds for their distribution into the following orders:—

'Amongst the unguiculate animals, the first is man, who, in addition to his peculiar privileges in every other respect, is distinguished, zoologically, by possessing hands on the anterior extremities alone, the posterior extremities being destined to sustain him in an erect position.

'The order which comes nearest to man—that termed *Quadrumana*—has hands on the four extremities.

'Another order, termed *Carnivora*, has not the thumb free and opposable on the anterior extremities.

'These three orders possess, likewise, severally, the three kinds of teeth; viz. molars, laniaries, and incisors.

'The quadrupeds of the fourth order, viz. the *Rodentia*, have the digits differing little from those of the *Carnivora*; but they want the laniary teeth, and have the incisors of a form and disposition altogether peculiar to themselves.

'To these succeed the animals whose digits now become much cramped, being sunk deep in large and, most commonly, crooked claws. They are further defective in the absence of incisor teeth; some of them even want the laniaries, and others are altogether destitute of dentary organs. We shall comprehend them under the term *Edentata*.

'This distribution of unguiculate animals would be perfect, and would form a very regular chain, if New Holland had not lately furnished us with a small collateral chain, composed of the *Marsupial* animals, all the genera of which, while they are connected by a general similarity of organisation, at the same time correspond, in their dentition and diet,

some to the *Carnivora*, others to the *Rodentia* and a third tribe to the *Edentata*.

'The ungulate animals are less numerous, and present fewer variations of form.

'The *Ruminantia*, by their cloven feet, their want of upper incisors, and their complicated stomach, form a very distinct order.

'All the other quadrupeds with hoofs might be united into a single order, which I would call *Pachydermata* or *Jumenta*, the elephant excepted, which might form an order of itself, having some remote affinities to the order *Rodentia*.

'Last of all come the *Mammalia*, which have no hinder extremities, and whose fish-like form and aquatic life would induce us to form them into a separate class, if their economy was not in every other respect the same as in the class in which we shall leave them. They are the warm-blooded fishes of the ancients, or the *Cetacea*, which, combining the powers of other *Mammalia* with the advantage of being sustained upon the watery element, include the most gigantic forms to be found in the whole animal creation.' (*Règne Animal*, 2nd edit. p. 65.)

Illiger, in primarily dividing the *Mammalia* into those with free and those with fettered limbs—the *pedes exerti distincti* contrasted with the *pedes retracti obvoluti*—made a more unequal and less natural partition than the threefold one of Aristotle. The seals and the whales balance all the rest of the class in the Illigerian system. The subdivisions, also, of these primary groups, based exclusively on characters of locomotion, although frequently ingenious, have met with little acceptance beyond some of the schools of Germany. De Blainville, in 1816, adopted a character from the reproductive system for the primary division of the *mammalia*, viz. into the *Monodelphes*, *Didelphes*, and *Ornithodelphes*. His orders are in the main a return to the Linnean system and nomenclature, with some peculiar views, as e.g. of the quadrumanous or primatial affinity of the Sloths, which have never gained acceptance. But his system indicates a clearer appreciation or stronger conviction of the value of the character of parity or imparity in the number of toes of the Ungulata, first suggested by Cuvier, than was subsequently entertained by the originator of the idea. The position of the Marsupial and Monotrematous quadrupeds at the bottom of the class *Mammalia*, and the higher value assigned to the group which they constituted, than that in the *Règne Animal* of Cuvier, were ideas also in closer conformity with nature.

C. Lucien Bonaparte made the most important improvement in the classification of *Mammalia* which has been proposed since the establishment of the natural character of the implantal or ovoviviparous division. He, adopting the primary division into *Placentalia* and *Implacentalia*, divided the former into the two subclasses *Educabilia* and *Ineducabilia*, the latter including the orders *Bruta*, *Cheiroptera*, *Insectivora*, and *Rodentia*, with the common character of *cerebrum unilobum*.

MANMALIA

Isidore Geoffroy St. Hilaire raises the *Marsupialia* into a distinct class, and literally exemplifies the idea of Cuvier, by placing its subdivisions as orders in parallel equivalents with the orders of the *Placentalia*.

Sir Everard Home proposed a system of classification of Mammalia according to the modifications of the placenta, which unites many animals by common characters which belong to wholly distinct types of organisation.

Prof. Owen, in 1857, after carefully maturing the observations of many years on the anatomy of the brain, the mode of reproduction of the teeth, the locomotive, generative, and tegumentary characters of Mammalia, laid before the Linnæan Society the following classification, which we reproduce below. The characters of each subclass and order will be found in its proper place.

SUBCLASS ARCHENCEPHALA.

Order 1. *Bimana*.

SUBCLASS GYRENCEPHALA.

A. Unguiculata.

Order 2. *Quadrumanæ*. Fam. Catarrhina, Platyrrhina, Strepsirhina.

Order 3. *Carnivora*. Fam. Digitigrada, Plantigrada, Pinnigrada.

B. Ungulata.

Order 4. *Artiodactyla*. Fam. Omnivora, Ruminantia.

Order 5. *Perissodactyla*. Fam. Multungula, Solidungula.

Order 6. *Proboscidea*. Fam. Elephantidæ, Dinotheridæ.

Order 7. *Toxodontia*. Fam. Toxodontidæ, Nesolontidæ.

C. Mutilata.

Order 8. *Sirenia*. Fam. Manatidæ, Halicoridæ.

Order 9. *Cetacea*. Fam. Delphinidæ, Balænidæ.

SUBCLASS LISSENCEPHALA.

Order 10. *Bruta*. Fam. Bradypodidæ, Dasypodidæ, Edentula.

Order 11. *Chiroptera*. Fam. Frugivora, Insectivora.

Order 12. *Insectivora*. Fam. Talpidæ, Erinaceidæ, Soricidæ.

Order 13. *Rodentia*. Fam. Nonclaviculata, Claviculata.

SUBCLASS LYENCEPHALA.

Order 14. *Marsupialia*. Fam. Rhizophaga, Poëphaga, Carpophaga, Entomophaga.

Order 15. *Monotremata*. Fam. Echidnidæ, Ornithorhynchidæ.

No linear arrangement of the orders of a class can ever express more than a part of their mutual affinities. If we were to place them according to their natural relations, the *Quadrumanæ* would occupy the centre of the class, as from these the greatest number and variety of affinities seem to radiate. Thus, the genus *Galeopithecus* leads to the *Chiroptera*, the *Lemur* to the *Carnivora*, the *Loris*

MANMEEA

to the sloths among the *Edentata*; while with the *Rodentia* the *Lemurs* claim close alliance through the *Cheiromys* or *Aye-aye*.

Amongst the *Carnivora*, *Cercopithecus* approaches the *Lemuridæ*, *Mydaus* the *Gymnurrine* Insectivores, and *Phoca*, *Hippopotamus* and the *Sirenia*. In the *Artiodactyla*, *Camelus* trends off towards *Equus*, *Sus* towards *Camelus*, *Moschus* towards *Dolichotis*. In the *Perissodactyla*, *Hyrax* indicates the Rodent type. The Elephant and the Capybara have some remote analogy, as pointed out by Cuvier. Toxodontia, Sirenia, and Cetacea have many points of analogy inter se. The Bruta have lost in the mailed *Glyptodon* a transitional step to the thick and tubercular-hided rhinoceros; while the *Megatherium* approaches the colossal Pachyderms, the Sloth the Ruminants, and *Manis* and *Orycteropus* respectively the Echidna and Ornithorhynchus. The Rodentia have the same scalpriform molars as the Aye-Aye, the Hyrax, the Toxodon, and the Wombat. In the Chiroptera, whilst *Pteropus* typifies *Galeopithecus*, *Vespertilio* approaches *Sorex*. But the most divergent affinities are observed in the Marsupialia. Here the *Dasyuridæ* and *Didelphidæ* typify the Soricidæ, *Charopus* represents *Macroscelidæ*, *Peromyscus* and *Myrmecobius* the *Erinaceidæ*, *Phascoglossus* *Lagostomus*, *Macropidæ* the Jerboas and Hares, *Petaurus* the flying squirrel, *Phalangistidæ* *Sciurus*, and *Phagcolarctus* *Bradypus*.

In such a reticulate weaving of affinities, under which image the true relations of the Mammalia, as at present known, can alone be impartially and faithfully expressed, it will be observed that the lower the order is in the class, the greater divergence of analogy it offers to the orders above it in the scale. Thus more points of analogy exist between the *Lissencephala* and *Lyencephala* inter se, than between the Unguiculate and Ungulate groups of Gyrencephalate Mammalia.

From different points at the base of this cone the connection may be traced with the inferior classes; the most direct transition appears to be made by the Monotremes to the class of Reptiles. The functions of the warm-blooded mammalia of the tertiary period were fulfilled during the secondary age by reptiles. Thus, in the oolitic seas, the whales were represented by the Ichthyosauria; whilst the extinct Pterodactyles represented the bats. The Mammalia which present the closest relations to birds are the marsupial petaurists and the arboreal Rodents; but the hiatus is great. Between mammals and fishes the reptiles interpose at all points.

Mammalogy (Lat. mamma, and Gr. λόγος). The science of Mammals; the doctrine of their organisation, habits, properties, and classification. [MANMALIA.]

Mammea (Mamey, its American name). A genus of *Clusiaceæ*, comprising *M. americana*, the fruit of which, under the name of Mammee Apple or South American Apricot, is much es-

MAMMEE

teemed in tropical countries. It is as large as a cannon ball, yellow, with the rind, pulp, and seeds bitter, but the intermediate flesh sweet and aromatic. The tree is a native of the West Indies and tropical America, but is cultivated and almost naturalised in some parts of tropical Asia and Africa.

Mammee. The *Lucuma mammosum*, sometimes called Marmalade-tree. It must be distinguished from the Mammee apple of the preceding article.

Mammifers (Lat. *mamma*, and *fero*, *I bear*). A term synonymous with Mammals or Mammalia.

Mammon (Syr.). Among the Jews, this word signified riches, or the god of riches. In the *Paradise Lost*, Milton represents Mammon as one of the fallen angels.

Mammoth (a word of Samoied origin, applied in Siberia to burrowing animals). The extinct elephant of Siberia, Northern Europe, and North America. Its remains occur chiefly, if not exclusively, in post-pliocene deposits. Its grinders are broader, and have narrower plates and ridges, than in other elephants. In several of the instances of Mammoth's tusks from British strata, the ivory has been so little altered as to be fit for the purposes of manufacture; and the tusks of the mammoth, which are still better preserved in the frozen drift of Siberia, have long been collected in great numbers as articles of commerce. The mammoth is more completely known than most other extinct animals by reason of the discovery of an entire specimen, preserved in the frozen soil of a cliff at the mouth of the river Lena in Siberia. The skin was clothed with a reddish wool, and with long black hairs. It is now preserved at St. Petersburg, together with the skeleton, to which parts of the skin of the head, the eyeball, the strong ligament of the nape which helped to sustain the heavy head and teeth, and the hoofs, remain attached. The mammoth seems to have enjoyed a wider geographical range than any other extinct elephant. Its remains have been found in the British Isles, continental Europe, the Mediterranean, Siberia, and throughout a large portion of North America, where it coexisted not only with the gigantic *Mastodon ohioiticus*, but also with a second species of true elephant (*E. texianus*), the teeth of which were more adapted to a succulent vegetable diet.

Man (a Teutonic word, from the Aryan root *man*, to think; hence Sansc. *menu*, a thinker). Of all living beings on the surface of this planet the first is *man*, who, in addition to his peculiar privileges in every other respect, is distinguished zoologically by possessing a hand on the anterior extremities only, the posterior or lower limbs being destined to sustain him in an erect position. He is, however, naked, and without natural defensive or destructive weapons.

The main points of internal anatomy in which man differs from or excels the lower animals are the following: First of all, in the

MAN

magnitude of the brain, which is relatively greater than the spinal chord and nerves in him than in any other animal. This superiority is chiefly due to the great development of the hemispheres of the cerebrum, which are likewise characterised in man by the number and depth of the convolutions, by which the cineritious and vascular surface is augmented. The parts which exist in the human brain to a greater extent than in the lower animals are the posterior lobes of the cerebrum, the corresponding horn of the lateral ventricle, and the lesser hippocampus.

Of the external senses, that of smell is the least developed; but both this and the other organs are well balanced, and in their organisation most delicate and perfect. The two eyes are directed forward; and thus, though man does not see on two sides at once, like many quadrupeds, there is more unity in the result of his vision, and he can concentrate his attention more closely on the objects of his scrutiny. The external ear, having little mobility or extent, does not increase the intensity of sounds; notwithstanding which, Cuvier well remarks that man best distinguishes their intonation. So also with respect to the organ of smell; though most animals excel man in their power of scent for particular objects, there are none perhaps which can distinguish so many varieties of, or which are so uniformly affected by, unpleasant odours. In the discrimination and delicacy of taste man has unquestionably the advantage over the lower animals; and in no species is the hand so framed, or the tactile extremities of the digits so expanded, or endowed with such an exquisitely sensitive and discriminative integument, as in man.

'Man,' says Cuvier, 'has a particular pre-eminence in his organs of voice: he is the only mammal that can articulate sounds; probably on account of the form of his mouth and the great mobility of his lips. Hence results his most valuable mode of communication; for of all signs that can be conveniently employed for the transmission of ideas, varied sounds are those which can be perceived at the greatest distance, and in most directions simultaneously.' [LANGUAGE.]

The position of the heart, which rests obliquely on the diaphragm, and on which depends the absence of the azygos lobe of the right lung, and of the thoracic inferior cava—both which exist in most of the inferior Mammalia—relates to man's erect position.

The alimentary organs of man indicate his natural destination for a mixed diet of animal and vegetable substances; but the prehensile faculty of his hands, and the intelligence which governs its application, permitted the teeth to remain of such forms and proportions as might simply serve to divide and crush the food which the hands carry to the mouth. Thus the canine teeth, though present and with crowns shaped for piercing, do not exceed the adjoining teeth in size, and no interval in the dental series of one jaw is required to receive a pro-

duced task of the opposite jaw when the mouth is closed; thus the dental series in man is not only equable, but unbroken. The fore teeth are framed for dividing; the back teeth have flat and tuberculate crowns for bruising; the short and but moderately strong jaws hardly admit of the mastication of herbage, or the devouring of flesh that has not been previously prepared by cooking.

The organs of digestion conform with those of manducation; the stomach is simple; the intestinal canal of mean length; the small intestines are provided with numerous transverse folds of the secreting and absorbing mucous membrane, called *valvula conniventes*; the large intestines are well marked; they commence by a short and wide cæcum, provided with a long, slender, and vermiform appendage.

The period of gestation is nine months. In general there is only one child at a birth; twins are born once in about five hundred cases of parturition, and more than that number is extremely rare. The fœtus of seven months is eleven inches in length; that of nine months eighteen inches. Those which are born prior to the seventh month usually die. The first or milk teeth begin to appear a few months after birth, commencing with the incisors; at two years the entire deciduous series, twenty in number, is attained. These are shed successively from about the seventh year, to be replaced by others. The eight deciduous incisors are succeeded by eight permanent ones, the four deciduous canines by four permanent ones; the eight deciduous molars by the eight bicuspidæ. Of the twelve true or posterior molars, which are permanent, there are four—one on each side of both jaws—that make their appearance at four years and a half; four more at nine years; the last four being frequently not cut until the twentieth year. The fœtus presents one-fourth of the adult stature when born; it has attained one half of it at two years and a half, and three-fourths at nine or ten years. Between the seventeenth and twenty-first years the growth almost entirely ceases. Man rarely exceeds six feet, and seldom remains under five. Woman is ordinarily some inches shorter. When the full stature is attained, the body generally begins to increase in bulk; fat is accumulated in the cellular tissue; afterwards the solids become rigid; the fat is commonly absorbed, the before smoothly-filled integument falls in wrinkles; and old age arrives, with decrepitude, decay, and death. Man rarely lives beyond a hundred years; and most of the species, either from disease, accidents, or merely old age, perish before that term.

'The child,' says Cuvier, 'needs the assistance of its mother much longer than her milk; whence results an education intellectual as well as physical, and a durable mutual attachment. From the long period of infantile weakness results domestic subordination, and, consequently, the order of society at large, as the young persons which compose the new families

continue to preserve with their parents those tender relations to which they have been so long accustomed. This disposition to mutual assistance multiplies to an almost unlimited extent those advantages previously derived by isolated man from his intelligence. It has assisted him to tame or repulse other animals, to defend himself from the effects of climate, and thus enabled him to cover the earth with his species. Circumstances, more or less favourable, have restrained the social condition within limited degrees, or have promoted its development. The glacial climates of the north of both continents, and the impenetrable forests of America, are still inhabited by the savage hunter or fisherman; the immense sandy or salt plains of Central Asia and Africa are covered with a pastoral people and innumerable herds. These half-civilised hordes assemble at the call of every enthusiastic chief, and overrun the cultivated countries that surround them, in which they establish themselves but to become enervated, and to be subjected in their turn to the next invaders. This is the true cause of that despotism which in every age has crushed the industry called forth under the fine climates of Persia, India, and China. Mild climates, soils naturally irrigated, and rich in vegetables, are the natural cradles of agriculture and civilisation; and when their position is such as to afford shelter from the incursions of barbarians, talents of every kind are mutually excited. Such were formerly (the first in Europe) Greece and Italy; and such is at present nearly all the happy portion of the earth's surface.'

The influences of climate, and of the different habits and social conditions thence resulting, are associated with differences of form, stature, features, and colour of the skin; not greater, however, than the corresponding differences which indicate varieties of a species in the lower Mammalia; and accordingly naturalists have distinguished, and have characterised with more or less success, different races or varieties of man. 'As the races and varieties of the domesticated quadrupeds, so also those of the human species, blend imperceptibly with each other; and the absence of well-defined boundaries depends not only on the gradual subsidence and change of those physical causes which probably gave rise to the original varieties, but also to the faculty common to the individuals of different varieties of the same species to produce, by their union, individuals capable of propagating the intermediate variety. Hence has arisen the difficulty of defining the primary races of man, and the discrepancy which exists in the conclusions of those naturalists who have devoted the greatest attention to this important and most interesting branch of zoology. Cuvier considers that three varieties are eminently distinct—the white, or *Caucasian*; the yellow, or *Mongolian*; the black, or *Æthiopian*.

'The *Caucasian*,' he observes, 'to which we belong, is distinguished by the beauty of the

MAN

oval which forms the head; and it is this one which has given rise to the most civilised nations—to those which have generally held the rest in subjection. It varies in complexion and in the colour of the hair.

The Mongolian is known by his projecting cheekbones, flat visage, narrow and oblique eyebrows, scanty beard, and olive complexion. Great empires have been established by this race in China and Japan, and its conquests have sometimes extended to this side of the Great Desert; but its civilisation has always remained stationary.

The Negro or Æthiopian race is confined to the southward of the Atlas chain of mountains. Its colour is black, its hair crisped, the cranium is contracted, and the nose flattened. The projecting muzzle and thick lips evidently approximate it to the apes. The hordes of which it is composed have always continued barbarous.

To the three primary races characterised by Cuvier, Blumenbach adds the *Malayan* and *American* races. Of the Malays, however, Cuvier asks, 'Can they be clearly distinguished from their neighbours on both sides, the Caucasian Indians and the Mongolian Chinese?' And with regard to the Americans, he states, 'They have no precise or constant character which can entitle them to be considered as a particular race. Their copper-coloured complexion is not sufficient. Their general black hair and scanty beard would induce us to approximate them to the Mongols, if their defined features, their nose as projecting as ours, their large and open eyes, did not oppose such a theory, and correspond with the features of the European.'

Dr. Prichard, however, considered that there are seven classes of nations which may be separated from each other by strongly marked lines.

The *first* class corresponds with Cuvier's Caucasian variety, but which Dr. Prichard prefers to call *Iranian*.

The *second*, which he terms *Turanian*, is equivalent to the Mongolian variety.

The *third* class are the native American races, excluding the Esquimaux and some tribes which resemble them more than the majority of inhabitants of the New World.

The *fourth* class comprises only the Hot-tentot and Bushman races.

A *fifth* class includes the Negroes.

The *sixth* class consists of the Papuans, or woolly-haired natives of Polynesia.

The *seventh* class includes the Alfourou and Australian races.

The above classification has not generally been adopted.

A study of the resemblances and differences of human speech in various regions and various ages, has added much and will contribute more to the true knowledge and definition of the primitive races of the human species. It has already led to the establishment of the following families of languages: The *Semitic*, to which belong the Hebrew, Arabic, Chaldean,

MANDELIC ACID

Syrian, Phœnician, and Ethiopian; the Aryan or *Indo-European*, which includes Sanscrit, Persian, Greek, Latin, German, and Celtic; the *Monosyllabic* languages, as Chinese, Thibetan, Birman, Siamese; the *Poly-synthetic* languages, a class including most of the American-Indian dialects. The combination of zoological, anatomical, and glossological characters, is still wanting to establish the exact characters and limits of the human races. [ANTHROPOLOGY.]

Manatee or **Manati**. A genus of Sirenian Mammalia, in which the molar teeth have square crowns marked by two transverse ridges. There are no incisors or canines in the adult. Species are known from the tropical seas of both Africa and America.

Manby's Shot. [LIFE-PRESERVING APPARATUS.]

Manchineel (Manicnella, the Spanish name). The *Hippomane manicnella*, a tree inhabiting the West India islands, and celebrated for its poisonous qualities. It is asserted that to sleep beneath its shade is fatal; and that the land-crabs found in the groves of manchineel become poisonous from feeding on its seeds. Although there is much exaggeration in these stories, no doubt exists of the deadly effects of manchineel juice when introduced into the system.

Mancinite. A brown silicate of zinc [SMITHSONITE] from Mancino, near Leghorn.

Mandamus (Lat. *we enjoin*). In Law, a prerogative writ, in the form of a command, issuing from the Court of King's Bench, directed to any person, corporation, or inferior court of judicature within the king's dominions, requiring them to perform various duties. It is grounded on the suggestion of a party injured by the acts or omissions of such persons or bodies; and lies, for instance, to compel the admission or restoration of a party applying to an office or franchise which has been illegally withheld, for the production of public papers, to compel the holding of courts, &c. The proceedings on mandamus have been remodelled by the Common Law Procedure Acts, 1852 & 1854, so as nearly to resemble those on an ordinary action.

Mandarin. The Portuguese term (from Port. *mandar*, Lat. *mandare*, to command) for a member of the official order of nobility in China. Mandarins are either civil or military: of the former there are nine classes, of the latter five. Although the mandarins are inferior in dignity to the higher class of nobility, whose dignity partakes of a personal character, they form the effective ministry and magistracy of the country. The Chinese equivalent of *mandarin* is *kouon*, which signifies literally a character.

Mandats (Fr.). A French government negotiable security, issued for a short time (under the Directory) after the withdrawal of Assignats [which see].

Mandelic Acid (Ger. *mandel*, an almond). A white crystalline acid obtained by the action of hydrochloric acid on bitter-almond oil. Its

MANDIBLE

chemical formula is $C_{10}H_8O_2 + H_2O$. It has also been called *Formobenzoic acid*, inasmuch as it contains the elements of formic acid and hyduret of benzoyle.

Mandible (Lat. *mandibula*, a jaw). In Zoology, this term is applied to the lower jaw of mammals, and to both jaws of birds (except by Illiger, who restricts its meaning to the lower jaw in this class also). In insects it is applied to the upper or anterior pair of jaws.

Mandibulates (Lat. *mandibula*). The name of a grand section of insects, including all those which preserve their organs of mastication in their last or perfect stage of metamorphosis.

Mandioc. The American name of a plant, otherwise called *Cassava*, which is cultivated within the tropics of America, for the sake of the fecula contained in its stems. It is the *Manihot utilisima* of botanists, formerly called *Jatropha Manihot*. Tapioca is one of its products. In its raw state the plant is poisonous; but by torrefaction and washing the fecula is rendered harmless. [MANIHOT.]

Mandragora (Gr. *μανδραγόρας*, corrupted into the French *main de gloire*, and the English *mandrake*). The name of a genus of *Solanaceæ*. *M. officinarum* is a beautiful autumn-blooming perennial, with wavy margined leaves and deep purple flowers. It has a thick fleshy root. The herb mentioned in Genesis xxx., which our translation renders mandrake, was probably some flower or root to which common belief attached value as a philter. The mandrake of modern as well as classical superstition is a herb supposed to have a resemblance to the shape of a man. Those who tear it from the ground are obliged to do so with peculiar ceremonials: shrieks and groans are heard to issue from it, which have the power of injuring the unwary person who hears them. Its favourite habitat was believed to be the ground under a gallows on which a criminal was hanging. When plucked, it was said to be useful in conjurations, for the transformation of men or beasts; and was also believed to enable the possessor to acquire riches at play, and to discover hidden treasures.

Mandrel (Fr. *mandrin*). In Mechanics, a revolving shank to which turners affix their work in a lathe; it also signifies the part of the anvil, or other tool, used by smiths to fashion the rough work upon.

Mandrill. A baboon. The name of the Catarrhine monkeys of the genus *Papio*, Cuv. They are the largest, most brutal, and ferocious of the baboons. The mandrill proper is the great blue-faced baboon of our menageries—*Simia Mormon* and *Maimon* of Linnaeus. It is of a greyish brown, inclining to olive above, with the cheeks blue and furrowed. The nose in the adult male becomes red, and even inclines to a fine scarlet at the end. It is difficult, says Cuvier, to imagine a more hideous or extraordinary animal. The male attains the size of a man, and is a terror to the negroes of Guinea and the other parts of Africa, of which this species is a native.

MANGANITE

Manes. The general name given by the Latins to the spirits of the dead. The word means 'the good ones,' and recurs in the name of *Mana*, an Italian goddess, and its opposite is found in the word *immanis*. They were commonly identified with the lares, and so received the name of *Dii Manes*. In the month of February, annually, all the Manes were propitiated in the *Feralia* or *Parentalia* during twelve days. The stones in the Roman burial-places, and their funereal urns, were generally inscribed with the letters D.M.S. (*Dis Manibus Sacrum*).

Manganese. This name is generally given to a black mineral, originally described, in the year 1774, by Scheele as a peculiar earth, afterwards shown by Gahn to be the oxide of a metallic substance which he called *magnesium*. This term, however, having been applied to the metallic base of magnesia, the word *manganese* has been adopted to designate the metal; and the ore above referred to has been called *black oxide*, or *peroxide of manganese*. The metal itself has a specific gravity of 8.013. It is grey, hard, brittle, and very difficult of fusion. The black oxide is largely employed as a source of oxygen, and is especially important from the use which is made of it in the decomposition of hydrochloric acid for the production of chlorine. Manganese has the atomic weight 28; and the black oxide, being a compound of 1 atom of manganese and 2 of oxygen, has the equivalent 44 (28 + 16). There is also a protoxide of manganese, composed of 28 metal + 8 oxygen, which is the basis of the salts of this metal. When hydrate or carbonate of potash, or nitre, are fused with peroxide of manganese in an open vessel, a dark-coloured compound is obtained, long known under the name of *chameleon mineral*, in consequence of its yielding in cold water a solution which is at first green, then blue, purple, red, brown, and ultimately deposits a brown powder, and becomes colourless. This substance contains *manganate of potash*. A compound of 1 atom of manganese and 3 of oxygen has been called *manganic acid*. In the pink solution, which is produced at once by the action of hot water, manganese exists in a higher state of oxidation, forming the *per-manganic acid*; in which 2 atoms of manganese are combined with 7 of oxygen. Both these compounds are very easy of decomposition, readily yielding oxygen to organic matters, and are used as deodorisers and disinfectants. Some of the proto-salts of manganese are used in calico-printing as the source of brown colours, and occasionally as deoxidising agents. Manganese is sometimes present in steel.

Manganese Spar. [RHODONITE.]

Manganite. Grey oxide of manganese. The purest and most beautifully crystallised ore of manganese, of which it is a hydrated peroxide. It occurs in columnar crystals, which are striated vertically and often grouped in bundles; also fibrous and massive, or radiating, and granular.

MANGE

Mange (Fr. *démanger*, to *itch*). An eruptive disease which attacks several domestic animals, especially the dog. It is said to resemble the itch, and, like that disease, to be produced by a minute species of acarus which burrows beneath the cuticle. It is stated that the fluid discharged from the eruption of mange, in horses and dogs, has produced the itch upon the human skin. It is produced by confinement, want of cleanliness, and bad food.

Manger. On Shipboard, the space near the hawse holes, bounded on the after side by a partition across the bows, called the *manger board*, to receive any water which may enter the hawse holes. This water, instead of being allowed to flood the deck, is forced to return through the scuppers.

Mango (mangos *marum*, in the Tamul language of India). The *Mangifera indica*, a very large fruit tree, inhabiting the tropical parts of Asia, throughout all which it is as extensively cultivated as the apple and pear are in Europe. Old specimens have been seen with a trunk from ten to fifteen feet in circumference. The fruit is something like a nectarine, but more compressed, longer, and more curved. It contains a large stone, covered with coarse fibres, which lose themselves in the succulent flesh. The wild and inferior varieties of this fruit taste so strongly of turpentine as to be wholly unfit for use by Europeans; but in the fine varieties this flavour is replaced by a rich sugary quality, which renders it very delicious. In this country the mango has rarely ripened its fruit; but it is commonly sold in a pickled state.

Mangold Wurzel or **Mangel Wurzel**. The root of the *Beta vulgaris macrorrhiza*. It is cultivated for the food of cattle, and for its saccharine juice. [BRET.]

Mangonel (Ital. *manganella*, Gr. *μύγανον*). An ancient engine of war, similar to the trebuchet. [TREBUCHET.]

Mangosteen. The fruit of the *Garcinia Mangostana*, growing in Java and the Molucca Islands: it is of the size of an orange, and of a delicious flavour.

Mangrove (probably an abbreviation of *mangle* grove, the former being the Malay name). A tree inhabiting the shores of the tropical parts of the world in either hemisphere, and well known to navigators on account of the dense groves which it forms even down into the water itself. It belongs to the genus *Rhizophora* (its name being *Rhizophora Mangle*), and is principally remarkable for its seeds germinating before they leave the case in which they were generated on the branches. The young radicle grows downwards through the humid air till it reaches the mud, in which it fixes itself, and then the leaves and new stem unfold at the opposite end. The White Mangrove is *Laguncularia racemosa*, and the Black Mangrove *Avicennia tomentosa*.

Mania (Gr.). Madness. It is defined to be delirium, unclouded by fever. The emotions are especially disordered in this form of

MANIPULUS

insanity. Violent expressions of passions attend the disease when acute.

Manicheists. The followers of Manes, an Oriental heretic of the 3rd century, who, having been ordained a Christian presbyter, attempted to effect a combination between Christianity and the current philosophical systems of the East. He pursued herein the same course with the Valentinians, Basilidians, and many others, whose leading ideas may be denominated Gnostic. He maintained a dualism of principles governing the world, and a succession of dualisms generated from them, like the Gnostic æons. All things were effected by the combination or repulsion of the good and the bad; men had a double soul, good and evil; even their bodies were supposed to be formed the upper half by God, the lower by the Devil. The Old Testament was referred to the inspiration of the evil principle, the New to that of the good. In the latter, Manes proposed many alterations, and maintained also the authenticity of various apocryphal scriptures. A great part of his system related to cosmogony and psychology. Like most other Oriental systems, the Manichean heresy was celebrated alike for the austerities which it enjoined, and for the scandalous excesses which were attributed to its most zealous votaries. The charge of Manicheism was frequently brought against the early reforming sects, such as the Albigenses, Waldenses, Picards, &c. (Beausobre, *Hist. Critique de Manichée et du Manichéisme*, Amst. 1734; Gieseler, vol. i. 150 (transl.), ii. 151, iii. 340; Milman, *Hist. of Christianity* ii. 322.)

Manifesto. In Politics, a declaration of motives publicly issued by a belligerent state, or by a general acting with full powers, previously to the commencement of hostilities. They are in the form of letters, with a superscription or heading addressed to the public in general, and signed with the name of the sovereign who sends them forth. The usage of issuing manifestoes is said to date so far back as the fourteenth century. The term is probably derived from the Latin words *manifestum est*, with which such documents usually commenced.

Manihot (its native name). A genus of *Euphorbiaceæ* cultivated in tropical America for the Mandioc or Cassava root furnished by one of its species, *M. utilissima*. They are shrubby plants, with palmatifid leaves, and fleshy roots, from which the Cassava is prepared. [MANDIOC.]

Manipulation. In Chemistry, this term embraces the manual and mechanical operations of the laboratory; and in the delicate details of analysis, as well as in the exhibition of class experiments, great skill and practice in manipulation are required. The processes of weighing, measuring, filtering, distilling, precipitating, dissolving, using the blowpipe, &c. all come within the meaning of manipulation.

Manipulus (Lat.). In Roman Military Antiquities, a subdivision of the cohort: so called from the handful of grass, straw, &c. which formed its original standard. A manipulus consisted of 60 men, one of hastati and

MANIS

principes of 120, when the number of the legion was 300. [LÆGION.]

Mamia. The name of a genus of Edentate Mammals, singularly characterised by being covered with large, strong, imbricated horny scales, like the Lacertine reptiles, and hence commonly called scaly lizards, and figuring in old zoological works among that class of animals. The manis, or pangolins, are, however, true warm-blooded mammals, and rank in the system of Cuvier among the Edentate order; of which they may be regarded as typical forms, being destitute of teeth, and provided with a tongue of extraordinary length, with associated glands for preparing an abundance of adhesive mucus. By this organisation they are peculiarly adapted to prey on ants, termites, &c.; and certain of their claws are extraordinarily developed, to enable them to break through the walls of the habitations of these social insects. The manis are confined to the warmest regions of Asia and Africa, where they play a corresponding part with that assigned to the true ant-eaters (*Myrmecophaga*) in South America.

Manitrunk. In Entomology, a term given to the anterior segment of the trunk, in which the head inosculates, or on which it turns.

Manna (the Hebrew form of this word is *man*; some hold that the Jews adopted the Arabic name, while others regard it as an Egyptian word). What we now call *manna* is a saccharine substance which exudes from the bark of various species of Ash, chiefly *Ornus rotundifolia* and *europæa*, species formerly referred to *Frazinus*, natives of the south of Europe, especially Sicily and Calabria. Manna is used in medicine as a mild aperient. It differs remarkably from common sugar in not being susceptible of vinous fermentation; so that, if mixed with common sugar and yeast, and subjected to the process of fermentation, the sugar becomes converted into carbonic acid and alcohol, but the manna remains unaltered in the liquor. When manna is dissolved in boiling alcohol, the solution, as it cools, deposits it in flaky and acicular crystals, often arranged in concentric groups. Manna, thus purified, has been chemically designated by the term *mannite*. Mannite is found in variable quantities in a great variety of plants, and is a product of the vinous fermentation of sugar. The composition of mannite is represented by $C_6H_7O_6$, or $(C_6H_5O_4 + 2H_2O)$.

Manna Group. The prepared seeds of *Glycerin fluitans*; also a granular preparation of wheat deprived of bran, used as an article of food for children and invalids.

Mannite. [MANNA.]

Manometer or **Manoscope** (Gr. *μάνος*, rare, and *μέτρον*, a measure, or *σκοπέω*, I view). An instrument for measuring the density of the air, or rather its elastic force, to which the density is proportional. [PNEUMATICS.]

Manor (Old Fr. manoir, from Lat. manco, I abide). On the introduction of the feudal system into England, and the consequent estab-

MANOR

lishment of the principle that every person, save the king, was dependent on a superior, the whole country was parcelled out into lordships or manors. These divisions have generally, but not always, the same boundaries as the parish, single parishes having sometimes two or more manors in them. All manors contained, under the lord, a number of freeholders owing suit and service, a number of *nativi* or villeins owing suit and labour, and a few peasants called *coterales*, who occupied huts with some small curtilage or garden annexed.

The manor court was an invariable accompaniment of the manorial system, and the records of these courts formed the evidence for which the customs of the manor were maintained. These customs present an infinite variety, though in consequence of the general enfranchisement of copyholds, the modern representative of the villein or base tenure, many customs have become obsolete. The manor court in mediæval times was the chief police machinery of the age. It took cognisance of breaches of the peace, and where it had the high jurisdiction, inflicted penalties for felony. It had a coordinate jurisdiction with the coroner over fraudulent dealers, and exacted fines for violations of the assize of bread and beer. The process was very simple and effective. The lord of the manor presided by his steward, and a jury variable in number was elected. Sometimes the jury chose the seneschal or steward. The first business of the jury was to enroll adults, if any appeared, in the decenna, or tything, a small fine being levied on registration. This regulation was part of the old view of frankpledge. Then they appointed ale-tasters, who licensed common brewers to broach such casks as the tasters declared to be equal to the strength or goodness designated by the assize. Heavy fines were inflicted on any breach of this regulation. Similarly they who sold bread contrary to the assize were mulcted.

The jury then presented all offenders against the peace. The commonest charges, as might be expected, were those of injurious language and assault. The culprit was said to be placed at the mercy of the court, and a small fine was levied for the offence. When the offence was committed by a married woman, the husband was mulcted, and pledges were exacted for payment of the fine.

The proceeds of all fines were paid to the lord. As the steward could inflict no penalty except on the presentment of the jury, a check was put on extortion by the feudal superior, and it was the plain interest of the lord to levy moderate fines on culprits. As the penalties became the property of the lord, the tenants could not or would not make the sentences of the court a means for individual prosecution, or, at least, of private advantage; while the authority of the court was habitually invoked in order to save the tenants from dishonest practices, or turbulent and violent acts. No manor, however, it appears, could take cognisance of any plea involving a

MANROPE

tenant's right to his lands, except, of course, in breaches of fealty. These pleas were reserved to the county court, or (when this court became obsolete) to the courts at Westminster Hall or the justices in eyre.

Manropes. On Shipboard, the small ropes used to assist in passing up and down gangways, hatchways, &c.

Mansard Roof. In Architecture, this word is applied to a curb roof sufficiently lofty to admit of an attic being lodged in it. The Mansard roofs are so named after their inventor, who introduced them in consequence of a municipal law fixing the height at which the front walls of houses might be built in Paris. They are characteristic of the architecture of the period of Louis XIV.

Mansie (Low Lat. mansus, mansum, a residence). The term used in the northern provinces of England and in Scotland to express a parsonage house.

Manslaughter. In English Criminal Law, this term is defined a 'felonious killing without malice, before the blood has time to cool,' including, in practice, both killing under the influence of sudden passion, and also killing by careless accident or negligence. It is thus distinguished from murder on the one hand, and from excusable or justifiable homicide on the other. The offence is felony, and the punishment varies from penal servitude for life down to imprisonment or fine of the slightest amount, according to the several circumstances of what is of necessity a very various class of actions. [HOMICIDE; MURDER.]

Mantelet. [MANTLET.]

Mantis (Gr. *a prophet*; applied by Theophrastus, *Idyl.* x. 18, to the cicada). A Linnean genus of Orthopterous insects, characterised by having the head exposed, and the body narrow and elongated; the palpi short, and terminating in a point; the ligula quadrid; the tarsi five-jointed; and the wings simply plaited longitudinally, and not ray-wise, like a fan. The true mantises—sometimes called *praying insects*, on account of the position of the anterior pair of legs, which differ from the rest—are found only in tropical and temperate climates. They are diurnal, and remain almost stationary on plants and trees; frequently resembling, in a remarkable degree, their leaves and branches in both the form and colour of the wings and body, and thus they deceive the smaller insects on which they prey. Their eggs are usually enclosed in a capsule formed of some glutinous substance, which hardens by exposure to the air, and is divided internally into several cells. It is curious to trace the correspondence with the vegetable kingdom already noticed in the wings and body continued into the form of the egg-capsules, which in many species closely resemble a seed receptacle of a plant, presenting regularly disposed ridges and angles, or even being bristled with little spines. The female attaches it by an adhesive secretion generally to the stem of a plant.

A second group of mantises, characterised

MANUFACTURE

by having the anterior legs like the following ones, now form a distinct subgenus, *Spectrum*, and are generally called *spectre insects*. They feed exclusively on vegetables, of which they singularly resemble the dried twigs. The progress of entomology has required further subdivisions of both the above groups.

Mantissa (Lat. *addition or overweight*). The decimal part of a logarithm. In Briggs' system the mantissa remains the same, and always positive, so long as the number has the same significant digits. On this account mantissæ alone are registered in tables of common logarithms. They differ from the true logarithms only by positive or negative integers, called *characteristics*, which can be easily supplied. [LOGARITHMS.]

Mantle (Lat. *mantellum*, Fr. *manteau*). In Architecture, the piece lying horizontally across from one jamb of a chimney to the other.

MANTLE. In Malacology, the external fold of the skin of the molluscs.

Mantlet (Fr. *mantelet*). A movable shield used as a protection to the sappers in carrying a sap towards a besieged place, or to protect the gunners at an embrasure. Mantlets are made proof against the fire of small arms.

Manual (Lat. *manialis, held in the hand*). A name originally applied to the Roman Catholic service book, from its convenient size (being such as might be carried in the hand); but it now signifies any work used chiefly for the purpose of reference.

Manufacture (Lat. *manufactus, made by hand*). In Political Economy, a term employed to denote the processes by which materials, already produced by labour, are made to undergo some change or modification, and thereupon become available or more convenient for human use. Some of the products of human labour, as coal, are immediately useful; but by far the greater amount of such materials as are intended to supply human wants or demands, require beyond the labour needed to produce or collect them a further manipulation, in order that they may serve the ultimate purpose for which they were originally sought. Thus, after the labour of the husbandman has been devoted to the production of corn, the labour of the miller and baker are required, that the corn be ground, dressed, and made into bread. So with the process of mining. The miner gathers the ores, or the crude metals of which he is in search, in order that the raw material may be handed over to the industry of another class of workmen, who fashion the produce of this rude labour into the various implements which the necessities of civilised societies require, or comfort and elegance demand. In common language, this secondary labour is called *manufacture*, not indeed with absolute correctness, for the agriculturist and the miner are effectively manufacturers as well as the miller, the baker, the iron-master and the smith, but the usage of language gives sufficient distinctness to the sense in which the term before us is employed.

MANUFACTURE

The province of manufacture, therefore, is to shape or modify materials with a view to the development of those powers or forces which they possess, and which are necessary, useful, or convenient to mankind. Some materials are produced by chemical changes in the constitution of objects, and the change necessary for their being made available for human use can be effected immediately by human labour; in some the change is brought about by natural chemistry, and human labour is employed indirectly towards their production. For instance, iron can be reduced from its ores by processes more or less complex, but an organic substance like wheat, wool, or meat, can be produced by natural processes only, chemical skill being wholly incompetent to synthesize the elements into which these products can be readily analysed, and so to produce them indefinitely and at pleasure. In these cases, all that human labour can effect is to select such localities as are fit, or most fit, for production, and to stimulate the natural process by such aids as science or experience have discovered. When the material has been procured by one or the other of these methods, it needs, as has been said, a further manipulation to render it useful. This process of manufacture is carried on, and the labour exerted on it is diminished, by the application of those principles by which progressive wealth is conditioned; those, namely, of the division of labour, and the economy of forces.

By the division of labour is meant that continual distribution of the various mechanical acts which contribute to a single result among an increasing number of agents or labourers. In order that a material may be rendered suitable for immediate utility or consumption, a great number of separate acts must needs be performed upon it. When the simplest object of common use is examined, it will be found that it is the product of a very large amount of distinct muscular efforts. A common pin, for instance, is a pointed piece of brass wire, covered with a thin coating of tin, and furnished with a head. Familiar as such an instrument is, and obvious as is its construction, it needs, in order to be produced, perhaps some fifty different acts of labour. The same remark would apply in still greater measure to a watch, or, as we are told, to a playing card. It will, however, be manifest, that if one person had to perform all these acts, much time would be lost in turning from one act to another; that the dexterity with which one habitual act is performed will be much greater than could be acquired if the same man had to perform fifty or a hundred separate acts; and that, as some of those acts are more difficult than others, there would, if the same person did all, be a great loss in the charge of production, because the lowest labour would be paid at the same rate as the highest. Hence, as every producer wishes to produce at the least possible cost, or charge, or labour to himself, and the same motive applies to the employer of a hundred or a thousand workmen as to an individual

labourer, there is always an increasing tendency towards splitting up complex operations into as large a number of separate occupations as possible, in order that the greatest results may be achieved with the least possible labour or loss, since all superfluous labour is a waste of force, and an economical loss. This collection, however, of separate labourers for the purpose of producing a joint or common result can be effected only by the employment of large capital in manufacture, and consequently by such arrangements as secure to a moral certainty a profit to the person who ventures on such an undertaking.

The same disposition which underlies all economical progress, the wish, namely, to achieve the largest possible results with the least possible expenditure, leads to that economy of forces which is the aim of manufacturing industry. It will be manifest that all value is achieved by labour exercised upon materials, and their qualities, in answer to an effectual demand for the produce. But although muscular and nervous labour, that is, work of the hand and brain, are needed to set those forces in motion and direct them to the required end, still there are natural forces which man may appropriate, and by which he can arrive at results far more stupendous than could be reached by the labour of his single arm, or by any human power, however unsparingly combined or applied. These supplementary forces are not only more effective, but they are far cheaper. The substitution of animal for human labour is a direct economy, the power exercised by a horse being far less expensive than the same amount of power supplied by a man. Similarly, and indeed in even greater measure, the force of running water is far more cheaply applied than animal labour can be; and in a fuller sense still, the late discovered power of steam is generally much less costly, and always much more effectual, than the agency of the natural motion of water and air. Hence it is that these powers of nature have been, on discovery, rendered available for human purposes; and hence, also, the energies of systematic discovery and careful adaptation are constantly called into activity by the same disposition to economise cost, and to diminish direct human labour. It is by such means that the progress of modern society has been so rapid; and the fruits of research and reason are, it may be fairly predicted, made so secure to the human race, that a decline into barbarism, and a loss of civilisation, with a retrogression such as that which ensued on the downfall of the Western Empire, may be pronounced to be theoretically impossible. Modern civilisation is so fenced about by the adaptation of natural forces, that it is not conceivable that any barbaric vigour should be able at any time to force its barriers and rife it of its superiority.

It is only in modern times that the inductions of physical science have been rendered available for the economical progress of society. And the reason appears to lie plainly in the

MANUFACTURE

fact that modern societies alone have freed themselves from the cancer of slavery. In ancient communities the growth of mechanical skill, except to a scanty extent in the arts of war, was checked by the absence of the motive referred to above. There is no impulse towards economising labour and supplementing the physical energies of man by the appropriation of natural forces, when labour is compulsory, and its fruits are denied to the persons who afford it. No nation, it may be broadly laid down, ever made any notable progress in those arts which are called generally manufactures, in which slavery was encouraged, maintained, or even permitted. The existence of this social anomaly is an absolute bar to all economical advancement. Military science may indeed achieve some victories over natural force, and appropriate some of those supplementary powers, but it does so only partially, and would not at all were it not that the duty of public defence being confined for obvious reasons to the free citizens, the impulse to the economy of labour in this direction does to some extent exist. But it has always been found that the progress even in this direction is scanty, states in which slavery prevails having been almost always led into the employment of mercenary troops, and with this practice necessarily losing the motive which, as has been said, is dominant in the progress of invention and adaptation, that is, economy of labour, of time, and of cost.

When a nation has no manufactures beyond those which are absolutely necessary for the supply of home wants, the *stationary* condition is soon reached. It seldom happens, however, that any country is so situated as to be absolutely deburred from any but a purely agricultural industry, though it may very well happen that communities may be too eager to enter into competition with foreign markets, or to preclude supplies from foreign markets, either by a bounty on their own produce, or by protection to the home manufacturer. There are, it may be safely asserted, no natural circumstances under which a protective policy entered on with a view to originate or sustain a domestic manufacture, is not followed by loss and inconvenience to the general interests of the community which adopts the restriction or the stimulant.

It is too often the case that prejudiced parties either ignorantly or maliciously argue a diversity of interest between one branch of industry, as the agricultural, and another, the manufacturing. The landlord as letting the use of the soil, the farmer as selling its produce, are as much interested, though indirectly, in the success of manufactures, as the manufacturer himself. For, in the first place, the success of any branch of industry implies a corresponding increase of purchasers and a corresponding power of purchase; and, in the next, the same intelligence which adapts mechanical forces to purely manufacturing purposes has led to those discoveries which have revolutionised agriculture, and increased in

modern times so notably the rate of production from the soil. A short-sighted policy sometimes sees profit in dear times, or under a temporary scarcity; but the farmer's trade is not in one commodity, but in many, and an increase in the price of one or two among the articles which he produces may be, and is, often compensated by a great decline in the demand for other articles. Free trade in corn has benefited the agriculturist and the landowner, because although one kind of produce has been cheapened, a great rise has occurred in the price of other agricultural products, and this rise, as is well known, has involved a great increase in rents. In short, any attempt to argue about the relative significance of different kinds of labour in the great staples of national industry, is equivalent to discussing which of the two numbers 5 or 4 contribute most to the product 20.

Some manufactures must always be carried on in every country, i.e. those of which the use is universal and the value low, and in which the cost of carriage is great and disproportionate to the intrinsic value of the article. Every community, therefore, carries on an industry in the commoner kinds of pottery, in ordinary agricultural implements, and in some of the coarser kinds of clothing. But when the circumstances of any particular community are favourable to a branch of industry, the produce of such an industry will sooner or later become the object of labour in such a community, and can never be advantageously stimulated by external aid or exceptional support.

Certain moral conditions must be fulfilled before manufactures can be practised advantageously, or indeed at all. We have already adverted to one, the condition, namely, of personal freedom in the labourer, and the right to appropriate whatever part of the general wealth of society the demand for his labour enables him to obtain. Freedom, indeed, is as essential in political economy as it is in morals, and the foundations of either science are equally sapped when the freedom of the agent is invaded.

Again, in order that manufactures may flourish, security must be afforded to the producer. It is vain to expect economical progress when property is insecure and governments are rapacious and negligent. The ravages of war are no doubt eminently destructive; but no foreign war, and no loss from public enemies, can equal the mischievous effects induced by a profligate, corrupt, or extortionate administration. Asia Minor and Syria, with the region lying between the two great rivers of Western Asia, are now among the most impoverished regions of the earth, though full of the relics of an ancient but imperfect civilisation, and through their present desolation giving abundant proofs of a vast and prosperous population in bygone times. The sole cause of the change is to be found in the character of the governments by which these regions have been so long afflicted. It is only

MANUFACTURE

in degree that all unwise or partial legislation fails to produce similar effects. The social system of France, and the iniquitous method of taxation which preceded the Revolution, entirely prevented the material progress of that country.

Again, in order that progress be made in manufacturing industry, it is essential that the commercial morality of the trading or producing class should be unimpeachable and exact. It has not rarely happened that a foreign trade has been lost by the shortsighted dishonesty of manufacturers, and that the efforts made to extend trade have been neutralised, from a well-founded impression that the manufacturer or merchant is unsafe or fraudulent. Even if a purchaser were always competent to pronounce at sight on the soundness of wares, it is inconvenient to be compelled to do so, and the adoption on the part of the producer of the maxim *Caveat emptor*, will be found to be rather cunning than wise, and ultimately not even cunning.

It is also very necessary that the relations of labour and capital should be satisfactorily balanced. Both must be sufficiently abundant in order that manufactures should exist at all, for labour is to be set in motion by capital, and capital will not be accumulated, or if accumulated will be wasted, unless labour in sufficient quantity be present for its employment. Hence any hindrance to the free circulation of labour or capital is a bar to the prosperous development of manufacture; and by parity of reasoning, distrust on the part of labourer or capitalist, or exaction on the part of the former, will tend to derange these relations, and induce an insecurity in the continuance of the industry. It is said, and probably with justice, that much of the local distress in certain manufacturing towns is due to the habit of irrational and unwarranted strikes. It is certain that every capitalist who engages in any manufacturing avocation, will take into his profit and loss account the risk of a compulsory cessation of the beneficial employment of his capital, and if the evil is perpetual, may cease to employ capital in the direction which exposes him to the danger. That an extension of primary education among the mass of the working classes is a powerful contribution to the growth of mechanical skill and manufacturing industry, will hardly be denied. The quickness with which an educated person can adapt himself to circumstances as compared with one who is deficiently taught, has been often commented on. But it may be urged with great force, that the value of such an education lies more in the aid which it gives to the possessor in understanding and improving his own condition, than in the special aptitude which he derives for a vocation the operations of which, by the effect of the division of labour, become more and more definite. The moral value of education cannot be overrated, and it is to the spread of this education that we must trust for the refutation of those erroneous

views about the relations of labour and capital which tend so much to interfere with the industrial energies of the community. And it has been found that educated workmen are not so valuable for the increase of their mechanical skill, as for the fact that reliance can be placed on their character, and confidence felt in their self-respect.

It has been stated, that there are few countries in which manufactures of some kind or other cannot be carried on. In order to utilise natural forces, and especially that force which has in effect completely changed the process of human industry, the power, namely, of steam, fuel must be cheap and accessible. Coal, the chief agent in the more important manufactures, has a very wide geographical range (few countries, except those in which the geology is almost entirely of primitive rocks, failing to supply it in a greater or less degree), and the list of coal-bearing regions becomes constantly larger in consequence of geological research. Even, however, in those countries where coal is deficient or absent, there are generally abundant metalliferous veins, and therefore a natural material for human industry. But it is also found that climate has much to do with particular branches of manufacture. It may be doubted whether machinery such as we are familiar with, could be worked continuously or safely in tropical countries. Where the temperature is high, it appears that the gear of delicate machinery gets rapidly out of order; and it is by the exceeding delicacy and precision of modern machinery that the greatest triumphs of manufacturing art have been achieved. Even, however, if machinery equally available for manufacturing purposes could be supplied for regions in which the mean temperature is high, there still remains the difficulty of supplying and accommodating labour in sufficient abundance and efficiency.

It has been said that silk dyeing can be carried on only under exceptional atmospheric conditions, and that no skill in manipulation, and no chemical art practised by English silk dyers, will enable them to compete successfully with the manufacturers of the south of France where the clearness of the atmosphere and the brightness of the sun give a gloss and finish to goods superior to anything which can be produced elsewhere. Similarly, the atmospheric conditions of this country, and the general humidity of the region in which the great cotton and woollen manufactures of England are carried on, enable the producer to spin a finer and tougher yarn than could be made in any other country. Spinners from the United States have been astonished at the excellence of the thread manufactured by their English rivals, and, despite all possible invention and adaptation, despair of equalling the perfection to which this art is brought. The secret, they find, lies in the climate; and it is asserted, that even if the supply of coal should fail, and it became necessary for this country to import fuel, England would still be the foremost coun-

MANUMISSION

try in the production of finer cotton and woolen goods. The time is probably far distant when the coal of this country will show signs of exhaustion, and by that time it is very likely that the cost of shipbuilding and freight will be so far reduced that coal may be imported at a comparatively trifling charge from the vast fields of Eastern America.

There is nothing, lastly, which appears at present to justify any alarm about the permanence of the manufacturing eminence of this country. The physical conditions which have induced the mercantile prosperity of the United Kingdom are generally permanent; and even those about the duration of which some alarm has been expressed, are at present so extensive as to make the contingencies contemplated exceedingly remote. Nor can it be doubted, that many changes are going on in the relations of capital and labour, from whose present antagonism some rational fear may be felt; but this conflict will ultimately tend to a more thorough harmony between jarring but mutual interests. It seems likely that the co-operative principle will, not long hence, occupy a very important position in manufacturing industry, and that a natural solution will be given to the grave questions which have latterly assumed so much prominence, by the union of rival interests in the same individuals. In such a case, if common integrity pervade these new establishments, there seems little doubt that greater effectiveness will be given to labour, greater elasticity to capital, and greater economy in production. (Babbage *On the Economy of Machinery and Manufactures*.) [TRADES UNIONS; LABOUR.]

Manumission or **Enfranchisement** (Lat. manumissio). The grant of liberty to a slave. Ancient charters containing such grants were frequently termed *charta ingenuitatis*. (See a law of William the Conqueror, *Lamb. Archæol.* 126.) The term *manumission* is derived from a practice adopted by the ancient Romans in enfranchising their slaves. The master seized the hand of the slave, and dismissed him with the words, 'Hunc hominem liberum esse volo.' Among the Romans there were two classes of manumission, called perfect and imperfect; the former of which was effected in three different ways. The enfranchisement was perfect—1. Per census; by which the name of the slave was, at the master's request, placed in the register of free citizens. 2. Per vindictam; when the slave was led before the prætor, and, the master having demanded his liberty, that magistrate laid the vindicta (or rod of office) on his head, with the words, 'Aio te liberum esse more quiritium.' 3. Per testamentum; by will. It was imperfect when the slave was enfranchised at private entertainments, or by letter. [CLIENT.]

Manures (Fr. manœuvrer=Lat. manu operare, to work with the hand—a derivation which seems to recognise the fertilising influence of mere tillage operations on the soil, as well as of direct additions of fertilising matter).

MANURES

Manures are substances added to the soil, with a view of accelerating vegetation, and increasing the production of the crops. Animal, vegetable, and mineral substances are used for this purpose. Decomposing animal matter of any kind forms one of the most powerful manures, and in many instances hastens the decay and decomposition of inert vegetable matters mixed with it; as in the mixture of dung and straw which forms the common offal of stables. All animal excrements are also powerful manures, and, when duly applied to the soil, soon exhibit their influence by the luxuriance of the crop. Manures act simply as supplying the building material which vegetable increase requires. All plants needing certain substances in certain quantities for their growth, the body which is present in the soil in minimo rules the crop. It is generally the case that nitrogenous compounds and phosphoric acid—more rarely potash and lime—are the substances thus present in minimo, an addition of which, whether in animal or vegetable or mineral compounds, to the soil is required in order to produce an abundant growth.

In all cases where animal manures are used, care should be taken that they are brought into action upon the soil as soon as they begin to decompose, or as soon as possible afterwards, and not suffered to rot, and exhale their best constituent parts whilst lying in the farmyard. The drainings and to a less extent the exhalations of a common dung-heap contain its most effective ingredients; and these are often suffered to go to waste, or to contaminate the air and collect in pools of filth. The fresh and the old manures of this description are known to farmers under the terms *long* and *short* dung: the advantages and economy of the former, when properly applied, cannot be doubted. Those animal manures which are slow of decomposition are most durable, and the more soluble substances are the more rapid in their operation. Of the former, one of the best is ground bones, which supply phosphorus to the soil and the crop. Of the latter, dissolved bones or super-phosphate of lime may be named as quick and efficient in action on those crops which require much phosphorus during their growth. Vegetable manures are often very effective, especially in the case of ploughing in a green crop; and inert vegetable substances may be rendered active by mixture with those which easily putrefy, or with animal matter. Mineral manures act not only by the direct addition of the ingredients needed for the food of plants, but also in some cases by their causticity, as is the case with quicklime, by which they decompose most organic bodies, such as roots, fibres, &c., and render them soluble and nutritious to the growing crop. They are also useful by altering the texture of the soil. Thus, sand may be called a manure for clayey lands, and clay and loam for those that are sandy. Upon the same principle, stiff soils are improved by paring and burning.

MANURES

In fact, it is only as supplying what is strictly speaking *mineral* food to plants that manures of all kinds tend to promote vegetable growth. Animal and vegetable manures do not enter plants as such, or as solutions of organic matter. They must be decomposed into their original mineral elements, and take the form of carbonic acid, ammonia, and the various mineral salts, before they can enter plants or promote their growth.

MANURES, ARTIFICIAL. The artificial manufacture of manure has arisen out of the inability of the guano trade to supply the demand for imported fertilisers which its own success had created. Since 1841, when 2,881 tons of Peruvian guano were brought into Liverpool, and when its wonderful powers as a manure were first realised upon a sufficiently large scale to produce conviction in the minds of farmers, there has been almost everywhere a demand for the means of thus adding artificially to the fertility of the land. But the supply of guano, far from being able to meet this increasing demand, has been falling off. The average receipts for many years up to 1858 had been 250,000 to 300,000 tons a year. Since then the average supply has not exceeded 150,000 tons a year. Owing to this unsatisfied demand, there has been a very large manufacture of fertilisers which take the place of guano. Bonedust and mineral phosphates of various kinds, rendered soluble by the addition of one-third their weight of sulphuric acid, nitrate of soda, and sulphate of ammonia, are the principal ingredients of which these artificial manures are made. It is now almost the general practice to use two or three cwt. per acre of the soluble phosphate, or so-called superphosphate of lime, as a preparation for the turnip crop; nor is it unusual to apply one cwt. or more per acre of nitrate of soda as a top dressing for the wheat crop. The rule is to apply the nitrogenous manures to cereal and other grasses, phosphatic manures to turnips, and alkaline and calcareous manures to leguminous plants, as beans, peas, and clovers.

Manuscripts (Lat. manu scriptus, *written by the hand*). Literally, writings of any kind, whether on paper or any other material, in contradistinction to such as are printed. Books were generally written upon vellum, after the use of papyrus had become obsolete, until the general introduction of paper made from rags, about the fifteenth century after Christ; and the finest and whitest vellum is generally indicative of great age in a manuscript. The dearth of this material gave rise to the practice of using old manuscript books on which the writing had been erased [PALIMPSEST], and also to that of abbreviations. These were carried to excess in the twelfth century, and from that time down to a period subsequent to the invention of printing, they were still in common use: in Greek printing they were usual until within the last fifty years. Of Latin MSS. those prior to the reign of Charlemagne

MAP

(A. D. 800) are considered ancient. Manuscripts of the early classical age were written on sheets rolled together. *Illuminated manuscripts* are such as are embellished with ornaments, drawings, emblematical figures, &c. illustrative of the text. This practice was introduced at a very early period; for we find the works of Varro, Pomponius Atticus, and others adorned by illuminations. But it was chiefly employed in the office-books of the early Christian church. The colours most employed for this purpose were gold and azure. Illuminations were in a high state of perfection between the fifth and tenth centuries; after which they seem to have partaken of the barbarism of the middle ages, which threw their chilling influence over every form of art. On the revival of the arts in the fifteenth and sixteenth centuries, many excellent performances were produced; but the art did not take root, and among the last specimens of illumination executed in this country was Cardinal Wolsey's *Lectionary*, at Christ Church, Oxford. [CODEX; DIPLOMATIC; PALÆOGRAPHY.]

Map (Lat. mappa, *a cloth*). A delineation of some portion of the surface of the sphere (terrestrial or celestial) on a plane. Terrestrial maps are *geographic* or *hydrographic*, as they denote severally a portion of the land or of the sea; the latter, however, are usually called *charts*. [CHART.] A map representing a small extent of country is called a *topographical map*.

Terrestrial Maps.—The object of a terrestrial map is to exhibit the boundaries of countries and the relative positions of their several parts. A perfect representation of a country should present all its parts, not only in their true relative position, but also in their just proportions. This may be accurately done on a globe; but as the earth's surface is spherical, it is impossible to represent any considerable portion of it on a plane so that the distances of places shall retain the same proportions which they have on the sphere, and geographers have accordingly had recourse to various methods of delineation, all of which have their peculiar advantages in particular cases.

One method is to represent the points and lines of the sphere according to the rules of perspective, or as they would appear to the eye, having some assigned position relatively to the sphere and the plane of representation. This method gives rise to the different modes of *projecting* the sphere, of which the three principal are the orthographic, the stereographic, and the central. The method of projection answers very well when the surface to be represented is small, and the eye is placed perpendicularly over it; but when it embraces a considerable portion of the sphere, the parts near the extremities of the map are much distorted. [PROJECTION.]

A second method is to suppose the surface to be represented to be a portion of the surface of a cone, whose vertex is somewhere in the polar axis produced, and which either touches

the sphere at the middle latitude of the surface to be represented, or falls within the sphere at the middle latitude, and without it at the extreme parallels. The conical surface is then supposed to be developed on a plane (which may be done); whence this method is called the *method of development*. Of this method there are various modifications: as that of Murdoch, who supposes the side of the cone to be parallel to the tangent of the meridian at the middle latitude, but to penetrate the surface of the sphere between the middle latitude and the extremities of the projected arc; that of De Lisle, who assumed the cone such as to intersect the sphere in the two parallels equally distant from the extreme and middle latitudes; that of Euler, who placed the apex of the cone at a determinate distance beyond the pole.

A third method is to lay down the points on the map according to some assumed mathematical law, the condition to be fulfilled being that the parts of the spheroidal surface to be represented, and their representations on the map, shall be similar in their small elements. Of such methods the best known is *Mercator's Chart* (which, however, may be produced also by development), in which the meridians are equidistant parallel straight lines, and the parallels of latitude are also straight lines perpendicular to the meridians; but of which the distances from each other increase in going from the equator in such a proportion as always to show the true bearings of places from one another. [MERCATOR'S CHART.] The size of the map of any given region depends upon what is called its scale. In England this is expressed by the number of miles represented by one inch of the map. Thus, our Ordnance maps are six inches and one inch to a mile respectively. On the Continent, the ratio of the map to the actual area is taken, and the scale is represented by a fraction, as $\frac{1}{1,000,000}$, $\frac{1}{50,000,000}$, &c.

Celestial Maps.—For the construction of his maps of the stars, the astronomer Flamsteed adopted the following method: All the parallels on the sphere are represented by straight lines, and likewise one of the meridians; namely, that which passes through the middle of the map, as in the annexed diagram. The parallels which are all perpendicular to this meridian have the same relative lengths as on the sphere,

and consequently the degrees of longitude are represented in their just proportions; that is, are proportional to the cosine of the latitude. If, therefore, the parallels be each divided into the same number of equal parts, a curve line drawn through the points of division will represent the meridians. By this method any distance in the direction of the parallels is equal to the corresponding distance on the

sphere; but it is evident that the map is much distorted towards the extremities, in consequence of the oblique directions of the meridians. Flamsteed's method is sometimes used in geography for representing countries which lie on both sides of the equator, in which case the distortion is less. A modification of it, which consists in substituting arcs of circles for the curved lines representing the meridians, whereby their obliquity is diminished, is extensively employed in the construction of maps.

For details respecting the general construction of maps, we refer the reader to the work of Mr. Jamieson on the subject; Malte Brun's *Geography*; Malte Brun's and Balbi's *Systems of Geography Abridged*; Murray's *Encyclopædia of Geography*; De Morgan's *Explanation of the Gnomonic Projection of the Sphere*; and particularly the *Traité de Topographie d'Arpentage et de Nivellement* of Puissant.

Maple. The popular name of the *Acer* family. The Common Maple is *Acer campestre*; the Norway Maple is *Acer platanoides*; the Sugar Maple, *Acer saccharinum*; and many other species are cultivated as ornamental trees. [ACER.]

Maranatha (Syr.). A form of anathematizing among the Jews, which was viewed as a tremendous denunciation. (1 Cor. xvi. 22.) It signifies 'the Lord will come;' i.e. to take vengeance.

Maranta (after B. Maranti, a Venetian physician and botanist). The genus which furnishes the true Arrowroot of commerce. The species are natives of tropical America, but are cultivated for the sake of their starch-yielding tubers in both the East and West Indies and tropical Africa. *M. arundinacea* especially, and also *M. nobilis* and *M. Allouya*, are thus grown in the West Indies; and both these and *M. ramosissima* in the East Indies. The fleshy jointed scaly tubers are reduced to pulp with water; the liquor is then strained, and the fecula allowed to settle; then again washed, and dried. The arrowroot thus obtained is a pure and nutritious starch. Other kinds of arrowroot are furnished by species of *Canna*, *Tacca*, *Curcuma*, *Manihot*, and *Arum*.

Marantaceæ (Maranta, one of the genera). The natural order of Endogenous plants, from which the most genuine kind of arrowroot is prepared. This substance is the starch contained in the tubers of *Maranta arundinacea*, and some other species, and of certain kinds of *Canna*. The *Marantaceæ* are very nearly the same as the *Zingiberaceæ*, from which they differ in the flowers being more irregular, and the anther having but one lobe instead of two.

Maraschino. [LIQUEURS.]

Marasmus (Gr. *μαρασμός*, from *μαρᾶναι*, I waste away). Emaciation; atrophy.

Maravedi. A Spanish coin of Moorish origin. At first it was made of gold, and Le Blanc states that in 1220 it was worth about 14s. of our present money. It has now become a copper coin, worth only 43-272 of an English penny.

MARBLE

(Fr. *marbre*, Lat. *marmor*). A term limited by geologists to the varieties of carbonate of lime which have a granular and crystalline texture. In sculpture, the term is applied to several kinds of stone susceptible of a good polish. The varieties of it are extremely numerous. The most valuable sorts used by the ancients were the *Pentelican*, which was white, and obtained from Mount Pentelicus in Attica; the *Parian*, also called *Marpeesian*, obtained from the island of Paros, which was of a creamy or waxy tint, as was that from Mount Hymettus, in Attica. Thasos and Lesbos also produced white marbles, which were in much repute. A place called Luna, in Etruria, produced a marble whose whiteness exceeded that from Paros; this is the famous Carrara marble of our time. Of the white marbles were those from Mount Phellens; from the neighbourhood of Coraños, in Phrygia; from Cyzicus, in Asia Minor; and the Marmor Phrygium, found near Synnada in Phrygia. The black marbles most used were from Tannarus, and the Numidian. The Chium Marmor, from the island of Chios, was of a dark chequered colour. The Obsidianum, procured from Ethiopia, was black. The Proconesian marble was white with black veins. Mount Taygetos afforded the Marmor Laconicum, which was green, and is better known by the name of Verde Antique. Marmor Libycum is the Rosso Antico. A marble of mingled green was obtained from Carystus. The Atrician marble, from Mount Atrax in Thessaly, was a mixture of black, white, blue, and green. The Tiberian and Augustan marbles were green, and brought from Egypt. The Marmor Memphites was green, and is what we call serpentine. Corinth produced a yellow marble. The Marmor Phengites was white, with yellow spots; the Rhodian was marked with spots of a golden colour, and that of Milos yellow (Giallo antico). In modern times the quarries of Carrara almost supply the world with white marble. Of variegated marbles there are many sorts found in this country of singular beauty; but they are not adapted for the sculptor. Ireland has supplied some beautiful specimens, but no quantity of marble fit for sculpture. France, Spain, and Portugal are all rich in marbles adapted for furniture and decoration, but not fitted for the sculptor.

MARO. The cake or refuse after expressing the oil or juice from seeds or fruits, as linseed, olives, grapes, apples, &c.; it is sometimes used for feeding cattle, as oilcake, but more commonly employed as manure.

Marcasite or White Iron Pyrites. A bisulphide of iron. The term Marcasite includes several varieties of Iron Pyrites, which have been named after the forms they present: viz. Cellular Pyrites, Cockscorn Pyrites, Hepatic Pyrites or Leberkies, Radiated Pyrites, &c.

It is used in the manufacture of sulphur, sulphuric acid, and sulphate of iron; but not to so great an extent as the ordinary sulphide. It was also formerly employed in jewellery and

MARCHES

for ornamental purposes, but has now gone out of fashion.

Maregraviaceæ (Maregravia, one of the genera). An unimportant order of hypogynous Exogens, belonging to the Guttiferal alliance, found in equinoctial America, and remarkable chiefly for their singular cucullate bracts.

MARCH (Lat. *Martius*, the month of *Mars*). The first month of the old Roman year, and the third of the English. (Sir G. C. Lewis *On the Astronomy of the Ancients*, p. 36.) In the ecclesiastical calendar used in England till the change of style in 1752, this was also the first month, as it was in the Roman. There is an old proverb still prevalent in Scotland, which represents March as borrowing three days from April, which have thence come to be designated the borrowed days. They will be found noticed in the *Complaints of Scotland*. Upon this subject Dr. observes, 'Those who are much addicted to superstition will neither borrow nor lend on any of these days. If any one would propose to borrow of them, they would consider it as an evidence that the person wished to employ the article for the purpose of witchcraft against the lenders.'

MARCH. In Military language, signifies the motion of a body of troops from one place to another. It consists of three cadences: 1. slow time, in which seventy-five paces are taken in a minute; 2. quick time, in which 110 paces are taken in a minute; 3. double time, in which 150 steps are taken in a minute. In slow or quick time a pace is 30 inches, in double time 36 inches.

MARCH. In Music, a military air, the original purpose of which is to regulate the steps and to animate the minds of soldiers. The march, however, has long been adapted to every species of musical instrument, and some of the most celebrated compositions of the greatest masters are in this style; as the March of the Priests in Mozart's *Zauberflöte*, the Peasants' March in Weber's *Freischütz*, and above all Beethoven's Funeral Marches. A march should be always in common time; but no general rules can be laid down for its composition.

Marchantiaceæ (Marchantia, one of the genera). [*HEPATICÆ*.]

Marches (A-Sax. *marc*, a mark or boundary). The name given to the borders or frontiers of any district; but more especially applied to the boundaries between England and Wales, and England and Scotland. The term is found in most of the Teutonic dialects. Several titles of dignity both in this and other countries derive their origin from their possessors having been appointed governors of the *marches* or frontiers of their respective countries; of these, *marquis* in England and *markgraf* in Germany are the most prominent. The title Earl of March, now enjoyed by the Duke of Richmond, was originally bestowed on Mortimer, because he was the governor or superintendent of the Welsh marches. In the middle ages, the name *marchers* was given to the noblemen who lived

MARCIONITES

on the marches of Wales and Scotland. According to Camden they had once their own laws, and even the power of life and death like petty kings; but these privileges were abolished by Henry VIII. There was formerly a court of the marches of Wales in existence, where pleas of debt, or damages not above the value of 5*l.*, were tried and determined.

Marcionites. The followers of Marcion, who in the second century adopted the Oriental notion of the two conflicting principles, and imagined that between them there existed a third power, neither wholly good nor evil, the Creator of the world and the God of the Jewish dispensation. The object of the Good Principle, or Supreme God, is to restrain the ambition of these two powers, which wage a constant war against each other as well as against Himself. For this purpose it was that He sent His Son Jesus Christ to destroy the Evil Principle on the one hand, and to counteract and coerce the power of the Jewish Deity on the other. The Marcionites were a branch of the great Gnostic heresy. Their opinions are found in the writings of Irenæus, Epiphanius, and Tertullian against them.

Marcosians. An early sect of Christians, a branch of the Gnostics, who derived their name from an Egyptian called Marcus, and reputed a magician. (Eusebius, *H. Eccl.* iv. 11.) The Marcosians had a great number of apocryphal books which they held to be canonical; and many of their fables are still in use and credit among the Greek monks.

Mare's-tail. The common name of *Hippuris*, a waterside weed.

Marekanite. A variety of Pearlstone, found at Marekan, in Siberia, in the form of small pearl-white spherules, composed of thin concentric layers.

Margaric Acid (Gr. *μαργαρον*, a pearl). This acid is obtained by the action of potash upon cyanide of etyl. It presents the appearance of pearly crystalline scales, which melt at 140°. The name was formerly applied to an acid obtained by the saponification of several oils and fats; but this latter is now regarded as a mixture of stearic and palmitic acids.

Margarite. A hydrated silicate of alumina, lime, and soda, named from its pearly lustre.

Margarodite (Gr. *μαργαρον*). A hydrated variety of Mica, with a pearly lustre; found, amongst other localities, in the granite of the south-east of Ireland.

Margin (Fr. *marge*, Lat. *margo*, *marginis*, an *edge* or *brink*). In Printing, the arrangement of the pages in a sheet at proper distances from each other, according to the size of the paper; so that when the sheet is printed and folded, the border of white paper round them shall be regular and uniform in every leaf of the book.

Margin of a Course. In Architecture, that part of the upper side of a course of slates which appears uncovered by the next superior course.

Margites (Gr.). The title of a satirical poem numbered among the works of the cyclic poets,

MARIOTTE'S LAW

and attributed to Homer. (Grote's *History of Greece*, part i. ch. xxi.) The subject of the poem, which has not come down to us, was the character of a silly empty-headed man (*μαργιτης*).

Margosa-tree. One of the names of *Melia Azadirachta*.

Margrave (Ger. *markgraf*, count of the mark, marsh, or frontier). A title of rank formerly used in Germany, and equivalent to the English marquis. [MARQUESS.]

Maria Theresa, Order of. A military order of Austria, consisting of grand crosses, commanders, and knights: founded in 1757.

Marigold. A name given to various garden flowers. The common Marigold is *Calendula officinalis*; African and French Marigolds are species of *Tagetes*; and what is called Corn Marigold is *Chrysanthemum segetum*.

Marine Glue. A cement made by dissolving equal parts of shell lac and caoutchouc in separate portions of rectified naphtha, and mixing the warm solutions.

Marine Metal. An alloy of lead and antimony with about two per cent. of mercury, introduced in 1833 by Wetterstedt for sheathing ships.

Marines (Lat. *marinus*, *belonging to the sea*). A corps of men enlisted to serve as soldiers on board ships of war and on shore under certain circumstances. They sometimes assist, particularly in the British service, in performing seamen's duties on board. Marines were first embodied in 1664. In 1684 mention is made of the duke of York's maritime regiment of foot; and in the reign of William III. several regiments were placed on the establishment: these, however, were subsequently disbanded. In the beginning of Queen Anne's reign, six regiments of maritime soldiers were raised; and though these were again disbanded in 1749, six years afterwards 130 companies were raised on the recommendation of Lord Anson, consisting in all of above 5,000 men. Since the commencement of the present century great additions have been made to this corps; and at present its strength amounts to 17,000 men, divided into four divisions (in 116 companies) of light infantry and one division (in twenty-four companies) of foot artillery. The men are clothed and armed in the same manner as the infantry of the line and artillery respectively. Commissions in the corps are not obtainable by purchase; and the officers rise by seniority, in the artillery and infantry respectively, from the rank of second-lieutenant to that of general. The staff of the regiment consists of an inspector-general, or deputy adjutant general, and an assistant adjutant general. The corps takes military rank between the forty-ninth and fiftieth regiments of foot. The officers have all army rank; which may be the same or higher than that which they hold in the corps.

Marionite. A variety of hydrated carbonate of zinc, found in Marion county, Arkansas.

Mariotte's Law. In Pneumatics, a general property of elastic fluids, namely, that the

MARIOTTE'S LAW

elasticity or pressure is directly proportional to the density; or, which is the same thing, inversely proportional to the space which the fluid occupies. [PNEUMATICS.]

This important relation between the elastic force and the density of gaseous matter, ought, in justice to the first discoverer, to be called *Boyle's Law*. In a tract published at Oxford in 1668, under the title of *New Experiments touching the Spring and Weight of the Air*, Boyle announced that the spring—that is to say, the elastic force—of air is directly proportional to its compression; which is equivalent to saying, that the elastic force is directly as the density, or inversely as the volume, under the same temperature. Boyle's experiments were made on atmospheric air confined in the closed end of a U-shaped glass tube, and compressed by the weight of a column of mercury. It does not appear that he took the precaution to expel the moisture from the air, and the greatest pressure he applied was only equal to four atmospheres; so that it may, perhaps, be said that his experiments were neither sufficiently accurate nor extensive to establish the general law, even in respect of atmospheric air, without mentioning the other gases. Mariotte's experiments were described in the *Memoirs of the Paris Academy of Sciences*, published about eleven years later, namely in 1679, without any reference to Boyle's announcement, which was possibly unknown to him; and as it was through this channel that the law became known to the continental philosophers, who were the first to perceive its importance, they naturally distinguished it by the name of the person whom they supposed to be its discoverer.

The relation in question has recently been investigated by M. Magnus of Berlin and M. Regnault of Paris, in a series of experiments, conducted with the utmost attention to every circumstance affecting their accuracy; and the results are interesting. If v denote the volume of a gas under the pressure p , and v' its volume under pressure p' , then the law gives $vp = v'p'$, whatever the pressures may be, if the temperature remains unaltered. But, on comparing the results of his experiments, M. Regnault has found that the above equation is not strictly true for any gas; and that, assuming $vp = v'p'(1+q)$, where q is a small correction, the value of q increases with the p . Thus the elastic force of atmospheric air at great pressures is slightly less than it would be if the law were strictly true. With respect to carbonic acid, the deviation is considerably greater. In the case of hydrogen the correction q becomes negative, so that while air and the other gases experimented upon were more compressed than they would be if the law were exactly followed, hydrogen was less compressed, and its compressibility was found to diminish as the pressure increased. But temperature has a considerable influence on these results; and as it was found that the deviation from the law

MARITIME LAW

diminishes as the temperature is increased, M. Regnault concludes that the law is only rigorously true when the gases are infinitely dilated, and that it becomes less and less exact in proportion as they are in a state of greater condensation. (*Mémoires de l'Institut*, tome xxi.)

Maritime Law. The law relating to harbours, ships, and sailors. It forms an important branch of the commercial law of all trading nations, and embraces an infinite variety of subjects, most of which have been defined under their respective heads. The most celebrated codes of maritime law have been: in ancient times, that of Rhodes; in modern times, the *Consolato del Mare*, a compilation supposed to have been framed at Barcelona as early as the ninth century; the laws of the Isle of Oleron, in the time of Richard I. of England; the laws of Wisby in the island of Gothland, to which some northern jurists have assigned an earlier origin than the laws of Oleron, but which there can be little doubt were merely a compilation from those above specified. But by far the most complete and well-digested system of maritime jurisprudence that has ever appeared is comprised in the *Ordonnance de la Marine*, issued by Louis XIV. in 1681, by which maritime law was elevated to the rank of a regular system, and which has formed the basis of many of the subsequent decisions of English, American, and other foreign courts. This excellent code was compiled under the direction of Colbert, by men of great talent and learning, after a careful revision of all the ancient sea laws of France and other countries, and upon consultation with the different parliaments, the courts of admiralty, and the chambers of commerce of the different towns. It combines whatever experience and the wisdom of ages had shown to be best in the Roman laws, and in the institutions of the modern maritime states of Europe. The edition of it, with a commentary, by Valior (La Rochelle 1766) is a standard work. In the preface to his treatise on the *Law of Shipping* (of which the edition by the present Mr. Justice Shée, 1856, forms the best English compendium on the subject) Lord Tenterden says, 'If the reader should be offended at the frequent references to this ordinance, I must request him to recollect that those references are made to the maritime code of a great commercial nation, which has attributed much of its national prosperity to that code—a code composed in the reign of a politic prince; under the auspices of a wise and enlightened minister; by laborious and learned persons, who selected the most valuable principles of all the maritime laws then existing; and which, in matter, method, and style, is one of the most finished acts of legislation that ever was promulgated.' [ADMIRALTY, COURT OF.] In addition to the well-known English work above cited, may be mentioned Ortolan, *Règles Internationales de la Mer*, 1845. A very important addition to the public law on this subject, bind-

MARJORAM

ing at least on those powers which were parties to it, was made by the 'Declaration respecting Maritime Law' of the congress at Paris, 1856, by which privateering was abolished, the neutral flag admitted to cover enemy's goods, &c. It is printed in the Appendix to Phillimore's *International Law*, vol. iii.

Marjoram. One of the aromatic herbs cultivated for culinary use. There are two principal sorts used, Winter Marjoram, *Origanum heracleoticum*, and Sweet or Knotted Marjoram, *Origanum Majorana*.

Mark. An old coin current in England and Scotland, valued 13s. 4d. A piece of money so called is at present used in Hamburg; it is equal to 1s. 4d. sterling.

Mark, Order of St. A Venetian order of knighthood; St. Mark the Evangelist having been the patron of that republic.

Market. [TRADE, HOME.]

Marking Ink. [INK.]

Marking Nut. In Botany, the seed or nut of the *Simicarpus Anacardium*, a tropical tree, related to the cashew nut. It derives its name from the fact that the juice contained in its fruits stains linen of a deep and indelible black colour.

Marl (Dutch marghel, from margh, *marrow*, whence marghelen, *to fatten land*). Marl is a mixture of carbonate of lime and clay in various proportions, and of different degrees of compactness and friability. In some marls the proportion of clay is small, in which case it acts on soils much in the same manner as chalk; but where clay is the predominant ingredient, it acts principally by altering the texture of the soil. Hence sandy soils are improved by marl, in consequence of its increasing their compactness and capacity for retaining moisture; while argillaceous marls applied to clays are of little or no use. From these long-established facts has arisen the old adage—

Who marls sand shall buy the land,
Who marls clay throws all away.

Marl is found in almost every country; not like limestone, in protruding rocks, but (from its friable nature, which causes it to moulder down into a comparatively earthy mass) under or near the surface of the soil, whence it is dug out and spread on the surface. Hence, while limestone is quarried, chalk and marl are dug out of pits. Marl has been in use in Europe since the time of the Romans. It is very generally used as a manure in France and Germany. In England it is most used in Norfolk.

Marling Spike. An iron bolt or pin, tapering to a point, for opening the strands of rope preparatory to splicing.

Marmatite. A variety of Blende in which iron, and sometimes cadmium, takes the place of a part of the zinc. It is found at Marmato, in South America.

Marmolite (Gr. *marmallos*, *to shine*). A foliated variety of Serpentine from Hoboken in New Jersey.

MARQUESS

Marmeratum (Lat.). In Architecture, a cement formed of a mixture of powdered lime and marble.

Marmose. The *Didelphis murina* of Linnaeus, a small species of opossum, in which the marsupial pouch is suppressed, being represented by two folds of the abdominal integument.

Marmoset. A name frequently applied to the Ouistiti (*Haples Jacchus*), and to other allied species of South American monkeys.

Marmot (Fr.). The Rodent animal so called is the type of a genus (*Arctomys*) nearly allied to the squirrels, being characterised by having five molar teeth on each side of the upper and four on each side of the lower jaw, all bristled with points, and indicative of a somewhat mixed diet. The marmots, however, in their general form are nearly the reverse of the squirrels, being heavy, with short legs, a middle-sized or short tail, and a large flat head. They pass the winter in a state of torpor, concealed in deep holes, the entrance of which they close with a heap of dried grass. They are natives of Europe and North America, live in societies, and are easily tamed.

Maronites. The followers of Maro, inhabitants of the mountains Libanus and Antilibanus in Syria, who adopted in the seventh century the opinions of the Monothelites. They continued to form a separate sect until the twelfth century, when they became reconciled to the see of Rome. The Maronite writers, however, have always maintained their freedom from the errors imputed to them, and declare themselves to have been uniformly attached to the doctrines of the Catholic church. [MONOTHELITES.]

Maroons (supposed to be derived from a word used in Spanish America, signifying *hog-hunters*). A name given in Jamaica to runaway negroes. When Jamaica was conquered from the Spaniards, a number of negroes, abandoned by their former masters, occupied some of the mountainous parts of the island, and caused great trouble to the colonists. About 1730 they became extremely formidable, but after a war of eight years they at length submitted to a capitulation, by which they were allowed to retain their free settlements in the heart of the island. In 1795 a portion of them again rose in arms, but were speedily put down, and transported to a new settlement in Nova Scotia. (Dallas's *History of the Maroons*.)

Marque, Letter of. A commission granted in time of war to a private person commanding a vessel to cruise at sea and make prize of the enemy's ships and merchandise; the ship so commissioned is sometimes called by the same name. [REPRISALS.] The word is derived from mark (Ger. *frontier*), as being a right of capturing property beyond the limits or frontiers of another prince.

Marquess. A title of dignity in England, France, and Italy, next in rank to that of duke. [MARCHES.] It is of German

MARQUETRY

origin; those military chieftains in the Teutonic kingdoms and empires which arose on the fall of the Western empire, who were intrusted with the defence of districts on the frontiers, having been styled *mark-grafen*, *margraves*, counts of the marches or frontiers (in Latin, *marchiones*). Many of these officers were appointed by Charlemagne, although he was not, probably, the first creator of the office. According to the ordinary course of the development of feudal institutions, these chiefs, from military governors appointed for life, became territorial potentates, holding their lands by hereditary right; and, on the decay of that system, this honour, like others, became merely titular. In England, the first marquess was Robert de Vere, earl of Oxford, created by Richard II., in 1387, marquess of Dublin for life. The next creation was of John de Beaufort, earl of Somerset, raised to the rank of marquess in 1397, which dignity he afterwards refused to bear, as a strange and novel one. (Nicolas, *Introduction to the Peerage*, lxxvi.) After that period the title fell into disuse until the reign of Edward VI.

Marquetry (Fr. *marqueterie*). In Architecture, inlaid work consisting of different pieces of many-coloured woods glued on to a ground usually of oak or fir, well dried and seasoned, which, to prevent casting or warping, is composed of several thicknesses. The early Italian builders used marquetry in cabinet work; and John of Vienna, and others of his period, by its means represented figures and landscapes; but in the present day it is chiefly confined to the ornamentation of floors, in which the various pieces of wood are usually disposed in regular geometrical figures, and are rarely of more than three or four species.

Marriage, Law of, in England. Previous to the passing of the first Marriage Act in 1754, the law of England was governed by the canon law; and, consequently, an agreement to marry, followed by consummation, formed, as it now forms in Scotland, a sufficient union. That statute first rendered necessary the preliminaries of the publication of banns, or the obtaining a license. It was amended by 4 Geo. IV. c. 17. But that Act imposed so many additional restrictions on parties wishing to become husband and wife, that it was found necessary to repeal it in all haste, and another statute was passed (4 Geo. IV. c. 76), by which English marriages were next regulated.

By this Act the banns of marriage are to be published three Sundays in a parish church, or public chapel of the Establishment, in the parish wherein both, or the parish wherewin each, of the parties dwell. A license is a dispensation by virtue of which marriage may be solemnised without the publication of banns. It is granted by *surrogates*, or persons having authority from the bishop. No license can now be obtained, unless upon affidavit that the parish or district in which the marriage is to be solemnised has been the usual place of residence of one of the parties for fifteen days immediately pre-

MARRIAGE

ceding the granting of the license. The affidavit must also declare that there is no impediment of kindred or alliance, nor any other lawful cause of hindrance.

By the Marriage Act 6 & 7 Wm. IV. c. 85 (amended by several subsequent Acts) a superintendent registrar of marriages was appointed, who is required to register marriages, and empowered to give licenses, &c., either himself or by inferior registrars. Places of worship, certified according to law, may be registered for the solemnisation of marriages, or they may be celebrated before the superintendent registrar himself; thus entirely removing the contract from ecclesiastical control. But all parties may, if they please, still marry in the parish church. A complete registration of marriages is provided by the same Acts.

A special license dispenses with all restrictions as to time and place of marriage. By a regulation of Archbishop Secker it is not to be granted except to persons of a specified rank; but in practice the privilege is extended as a matter of favour.

The power of parents and guardians, in restricting the marriage of minors under their tutelage, is now confined within the following limits. The publication of banns is void, if the parent or guardian of either party declare, or cause to be declared, their dissent in public at the time of the proclamation. In case of marriage of a minor by license, the father or guardian, or if none, the mother or the guardian appointed by the Court of Chancery, must give consent, and such consent must be notified in the affidavit on application for the license. If consent be unreasonably withheld, the only resource of lovers against the flinty hearts of parents or guardians is by petition to the lord chancellor, who may, if he please, interpose his judicial authority in favour of their union.

Marriages are void if solemnised in a wrong name. They are also void where there is a prior existing marriage, and in case of lunacy or incapacity, or of relationship within the prohibited degrees.

Proof of a marriage is by the evidence of a party who was present at the celebration; or by production of the parish register, and showing the identity of the parties.

Marriage is voidable by legal proceeding, where such marriage has been contracted under a canonical impediment, such as bodily incapacity of either of the parties. Marriages solemnised by force are also voidable, and such as are contracted in error under certain circumstances. A voidable marriage is good to all intents until rendered void by a sentence of the court.

Other matrimonial causes are—1. Jactitation of marriage. When one party gives out or reports that he or she is legally married to another, the person injured may obtain a decree condemning the other to *silence*, with the costs of the proceeding; and unless the defendant proves marriage, silence is enjoined, which is the only remedy the matrimonial court can give.

MARRIAGE

The Ecclesiastical Courts had until 1857 the cognisance of *matrimonial causes*. But in that year, by the Act 20 & 21 Vict. c. 85, their jurisdiction in this respect was entirely abrogated, except for the purpose of granting marriage licenses: and was transferred to a new Court of Record, entitled the Court for Divorce and Matrimonial Causes. At the same time very important changes in the law itself, as regards these proceedings, were effected.

The powers of this court now extend to—

1. Decrees establishing the nullity of marriages contracted under legal impediment.

2. In suits of jactitation of marriage: that is, where one party falsely asserts that he or she is married to the other.

3. Sentences of judicial separation: which have the effect of what under the former law was termed a divorce *à mensâ et thoro*: and may be obtained by either party on the ground of adultery, or cruelty, or desertion without cause for two years.

4. Dissolution of marriage: which may be obtained on the suit of the husband for the wife's adultery, and on the suit of the wife for adultery and cruelty, or adultery with incest or certain other aggravations. Until 1857 divorce *à vinculo* had been legally unknown in England, as it is in countries governed by the maxims of the canon law, and could only be obtained through the medium of a special Act of Parliament. In that year, by the Act 20 & 21 Vict. c. 85, it was for the first time rendered generally lawful. At the same time, the old action for damages for *criminal conversation* was abolished; but the husband may still claim damages from the adulterer, either in his petition for divorce or separation, or by a distinct proceeding.

5. A suit for restitution of conjugal rights is to compel mutual cohabitation. It is doubtful whether any deed of separation, or anything short of a sentence by the court, can bar the complainant of his or her right to promote this suit; but cruelty or adultery may be pleaded in reply, as constituting lawful grounds for separation.

6. Alimony is that legal proportion of the husband's estate which, by the decree of the ecclesiastical court, is allotted to the wife for her maintenance during the pendency of a suit between them; or after a sentence of divorce *à mensâ et thoro* by reason of the cruelty or adultery of the husband, the permanent allowance to be paid to the wife during their separation. The quantum of alimony is decided by the court on consideration of the whole circumstances of the case: e.g. a third or a moiety of the husband's property.

Marriage, its Effect on Property.—The consideration of the legal effect produced by marriage on the property of the parties contracting it divides itself into—

The law of husband and wife: 1. As it respects property acquired by either before or after marriage.

2. As its dispositions are affected by separation or divorce.

As to real property. If the wife is seized of lands or tenements in an estate of inheritance, and dies having had issue born living, the husband is entitled to the lands or tenements for his life, being tenant, as it is termed, by the curtesy of England; and this, whether the lands be held by a legal or equitable title.

Dower is now, since the statute 3 & 4 Wm. IV. c. 105, the wife's right to one third part, for life, of all estates of inheritance which her husband dies solely entitled to in possession. It formerly attached to all estates of inheritance of which he was at any time possessed, so that he could not defeat her title by alienation, but to legal estates only. Since the 1st January, 1834, the period at which the above-mentioned Act came into operation, equitable estates are also subject to it. It has long been customary to bar this right to dower by various complicated processes, which the law has permitted to defeat the wife's claim; and especially by settlements before marriage, giving a jointure or provision in lieu of dower. It may now be barred by the husband's alienation in his lifetime; or by his will; or by a declaration in the deed of conveyance of the land to the husband. Anciently a *feme covert* could only alienate real property by the public solemnity of a *fine*; but now she may do this by a deed executed after her examination by commissioners, to show that no control is exercised by the husband.

As to personality: all the *personal* property to which a woman is entitled vests in her husband by marriage. Her *chattels real*, that is, leasehold property for a term of years, will revert to her if she survive him; and although the husband may alienate them in his lifetime, he cannot dispose of them by will. But should he survive her, they are his absolutely. Her *chattels personal*—money and goods—are his without restriction, to give or bequeath as he pleases even in her lifetime. Her *chores in action* (that is, property of which there is no immediate occupation, as debts due to her, money in the funds, &c.) are the husband's property *conditionally*; that is, if he reduce them into possession by exercising his rights over them during her life. If not, they survive to her absolutely; and should she die first, he only takes them as her administrator, which he is by right. Any property, however, whether real or personal, may be given to a woman for her separate use, which will exclude the husband's right, and she may be restrained from alienating the property during coverture.

If the husband die intestate, the wife is entitled to half his personal property if there be no issue, and to one-third if there be issue.

The husband is liable for all his wife's debts and engagements made while unmarried; but not for such as she may have contracted during a former marriage. But he is released from his liability by her decease; and if he die first, she only is responsible. For debts contracted by the wife during marriage the husband is not

MARRIAGE

liable unless they have been contracted with his consent, express or implied; and this implied assent gives rise, as may well be supposed, to numberless questions in courts of law.

As to the acts of husband and wife before marriage. Since 1837 (1 Vict. c. 26), 'Every will made by a man or woman is revoked by his or her subsequent marriage,' except in certain peculiar cases where made under a power of appointment.

Marriage settlements are contrivances to modify the effects which would be produced by the mere act of law on the rights of the respective parties; and also to insure a provision for issue. It is usual to vest the property of both parties in trustees; generally for the benefit of the husband during their joint lives, then for the benefit of the survivor, after his or her death for the benefit of the children, in such proportions as the nature of the property or circumstances of the family may dictate. But it is usual to give authority to the parents by means of a *power* to vary the children's relative proportions. A jointure, although, in the strict sense of the word, a joint estate to husband and wife, is in practice usually a rent charge to the wife, secured on land, to take effect immediately on the husband's death, and to secure a competent provision for her during her life at least; it is usually provided by settlement, and bars dower. Pin-money is an annual income settled before marriage by the husband on the intended wife for her personal expenses.

But in other cases, and especially when the casualties of a trade render it desirable to secure a certain protection, it is very common to give the first life interest in the settled property, or part of it, to the wife for her separate and inalienable use, free from the debts or control of the husband. Where bequests are made to a married woman for her separate use, and no trustees are named to protect them, a court of equity will consider her husband a trustee for her. She may sue him, or any other person, in those courts, in respect of such property. Her savings out of it are likewise hers in separate right.

A married woman has also a claim, in a court of equity, to a provision out of her own property in several cases, especially where the husband deserts or ill-treats her, or where, being a ward of chancery, she is clandestinely married; and recent legislation has given her in many instances a more summary remedy in such cases. A husband is not held liable for debts contracted by his wife, even for necessities, if he have turned her out of doors for adultery; or if, after being turned out, she commit adultery; or if she depart from him without his consent; or if she elope with an adulterer; or if the husband and wife separate by mutual agreement, in cases where the wife has separate means, or is provided for by separate maintenance. As to the effect of divorce or separation on property: the sentence of a court pronouncing a marriage void ab initio destroys the husband's rights over the property of the wife. And dower is

lost if the wife elopes and lives in adultery, or is attainted of treason or felony. Under the recent Acts of Parliament regulating divorce, the court has large power, both in cases of divorce à vinculo and of judicial separation, to make such orders respecting the property of the parties, even though in settlement, as may be thought expedient for the benefit of the children and of the parties themselves. On judicial separation obtained by a wife on account of the misconduct of the husband, she is entitled to *alimony* out of the husband's property [see above].

Lastly, as to criminal law: bigamy, or polygamy, is a felonious offence, punishable by penal servitude; and is now (since the statute 9 Geo. IV. c. 31) equally punishable, although the second marriage took place out of the jurisdiction of English law.

A wife committing any felony, except murder or manslaughter, in company with her husband, is not responsible for the offence; but she is indictable for high treason so committed.

Absence of Husband or Wife for a period of seven years is allowed by 24 & 25 Vict. c. 100, s. 57, as an exemption from the penal consequences of bigamy.

Marriage, Law of, Foreign. By the law of Scotland, marriages merely contracted by declaration, acknowledgement, or before witnesses, are held valid. By that of France, and all countries in which French jurisprudence is established, marriage is a civil contract only, regulated by articles 144 and following of the Code Civil. It cannot be contracted by a male before eighteen, or by a female before fifteen. The consent of the father and mother (if dissentient, the father overruling) is required until twenty-five and twenty-one respectively; and until thirty and twenty-five this consent must still be applied for, although marriage celebrated without it is not void. Marriages within prohibited degrees are absolutely null. But marriages in other respects contrary to the law are annullable on application of the proper parties.

Dissolution of marriage can only arise by death, natural or civil, that is by way of legal punishment. Divorce is altogether illegal, having been introduced into the law only in 1792, and expunged from it in 1816.

In the United States of America, marriage is likewise a civil contract only, but it is regulated by the laws of each state respectively.

The question of the validity in one country of marriages good according to the laws of another, is one of the most complicated, it may be added, one of the most unsettled, which remains in international jurisprudence. If married citizens of one country transfer their domicile to another, their marriages are, of course, valid in the country of their adoption, whether in accordance or not with the law thereof. But when the citizens of one country marry in another country, questions of great difficulty, and which, as has been said, no general agreement of jurisprudence has settled, are apt to arise; and these are still further complicated when the parties contracting

marriage are of different nationalities. As a general rule, marriage, like other contracts, is to be judged of by the *lex loci*. Consequently two English subjects marrying in France, according to the formalities of French law, contract a marriage valid in England. On this principle, the so-called *Gretna Green marriages* by English persons in Scotland were valid until checked by Act of Parliament in 1856. But, in the language of Mr. Story, 'the most prominent, if not the only known, exceptions to this rule are those involving polygamy and incest; those positively prohibited by the public law of a country from motives of policy; and those celebrated in foreign countries by subjects entitling themselves under special circumstances to the benefit of the law of their own country.' (*On the Conflict of Laws*, ch. v.) On this principle it has been recently decided, though not without considerable question, that a marriage by an Englishman with his deceased wife's sister, contracted in Germany, where such marriage is lawful, is invalid here. French jurisprudence, it may be added, appears to be more jealous of the maintenance of its own special marriage law in the case of marriages contracted by Frenchmen in foreign countries, than is our own.

Marrow, Vegetable. A variety of *Cucurbita ovifera*, cultivated for the sake of its fruits, which in the young state form a delicate esculent.

Marrubium. The genus of Labiate plants which includes the Horehound, an erect branching greyish-looking herb, with roundish wrinkled leaves, and whitish flowers crowded in the axils. It is found wild in this country, as well as throughout Northern Asia and Europe, and has bitter tonic properties. It is a favourite domestic remedy in chest complaints.

Mars (Lat.). In the Solar System, one of the old planets, and the fourth in the order of distance from the sun. The mean distance of Mars from the sun is 1·5236923, the mean distance of the earth from the sun being 1: it is, consequently, about 142,000,000 miles distant from the sun. Mars performs his mean sidereal revolution in 686·979 mean solar days, and his synodical revolution (that is, his return to the same position in respect of the earth and sun) in 779·82 days. His orbit at the beginning of the present century was inclined to the ecliptic in an angle of $1^{\circ} 51' 6''$; and its eccentricity is ·093311. His apparent diameter varies from $3\cdot6''$ at his greatest, to $18\cdot28''$ at his least, distance from the earth. At his mean distance the apparent diameter is $6\cdot29''$. The diameter of the planet (in which the ellipticity is extremely small) is 4,113 miles. Mars has a rotation about his axis which is performed in 24 h. 39 m. 22·62 sec., according to the latest researches. The inclination of the axis to the ecliptic is $28^{\circ} 51'$; the longitude of the pole of the planet being $349^{\circ} 1'$.

In consequence of the position of Mars in the system, and his eccentric orbit, he is sometimes so near to us that it is possible by means

of powerful instruments to scrutinise his surface rather closely; and it is not too much to say that at the present time materials exist for the construction of a map of the equatorial and southern parts of the planet, which shall show the position and outlines of the continents and seas with some degree of accuracy. As the north pole of the planet is tipped away from us when most favourable oppositions occur, so much cannot be said for the northern hemisphere.

To the other points of interest furnished by the planet must be added that of resemblance to our earth. That it has land and water, winter snows, summer thaws, and wind-borne clouds, has now been placed beyond all doubt, and it has been shown that its extreme temperatures are probably not far different from our own. The water shows itself in the telescope by a greenish tint, while sometimes the land appears red, and on this account it was once supposed that something like a red sandstone formation had a large development in our sister planet; but close observation in 1862 led one of the observers to surmise that this red colour might be due to the absorption of the planet's atmosphere. This suggestion has since been confirmed by means of spectrum analysis. The dazzling brilliancy of the polar snows (which are not always concentric to the pole of rotation) when observed near the limb of the planet is such that by an effect of irradiation they appear to project beyond it. The rate at which the snow melts is sometimes extremely rapid, and as a result the snow cap is reduced at a period equivalent to our July to an extremely small patch lying very near the pole. Some recently published drawings of the planet by Lord Rosse and another observer will be found in the last volume of the *Memoirs of the Royal Astronomical Society*.

Mars or Mavors. An ancient Latin god, early identified with the Greek Arès, but essentially distinct in conception from the idea of that god. [ARÈS.] The Sabine and Oscan form of the word was Mavors, and Mars itself is contracted from Mavors or Mavors. At Rome he was honoured as the progenitor of Romulus, the founder of the city, of which he was held to be the protector; and in his honour the Latin husbandmen used to offer up a sacrifice, called *suovetaurilia*. [LUSTRATIO.] The priests of Mars were called *salii*, and to their care was intrusted the sacred shield (*ancile*) which was said to have fallen from heaven during the reign of Numa. [ANCILIS; SALII; THOR.]

Marseillaise Hymn. The origin of this song, which has played so important a part in the revolutions not only of France but of other continental states, was long involved in obscurity; but there seems to be now little doubt that both the words and music were the production of Rouget de Lille, a French officer of engineers, who was quartered at Strasburg in the year 1792, when Marshal Luckner commanded the army, at that time entirely composed of young conscripts. According to a story which seems well authenticated, they

MARSH

were first produced in society by the author at the house of Baron Dietrich, in that city, in April of that year, as the *Chant du Départ de l'Armée du Rhin*. It is, however, necessary to add, that a claim for the music has been advanced, and pretty strongly supported, on the part of the Germans: on the supposition that it is borrowed from the *Credo* of a mass composed by Holzmänn.

The song is said to have been styled the *Marseillaise Hymn* from a body of troops, on their march from Marseilles, having entered Paris playing that tune at a time when it was little known in the capital. See the subject fully discussed for the last time, in an article contributed by M. A. Rouget de l'Isle to the French journal *l'Intermédiaire* for Sept. 20, 1864.

Marsh (Old Eng. *mareis*, Fr. *marais*, Lat. *mare*, a sea or pool). The name given by geographers to districts maintained in a state of moisture by the waters of a river, or of springs which cannot find an easy vent; the drainage of some of these marshes, such as the Harlem Meer, the Whittlesea Mere, &c. constitute the greatest triumphs of modern engineering.

MARSH. A flat surface, the soil of which is so far saturated with water throughout the year as to be unfit for culture by the spade or plough; but not so much as to prevent it from producing coarse grasses, and other kinds of herbage. Marshes are generally situated in bottoms, where they are kept moist by the water which descends from the surrounding lands; or along the banks of rivers or lakes, where their humidity arises from their being nearly on the same level with the adjoining water. Where a marsh is situated so as to be occasionally overflowed by the sea, or by a river up which the tide flows, it is called a salt marsh; and the herbage produced by such lands is found highly conducive to the health of animals which pasture on them for a certain portion of the year, from the alterative effect of its saline properties.

Marsh Gas. *Fire-damp, light carburetted hydrogen, or hydride of methyl.* This gas is evolved in large quantities from the seams in coal-mines, and is also one of the gaseous exhalations from marshes and stagnant pools. It is always present in coal-gas, mixed however with other gases. It can be prepared artificially either by bringing zinc methyl into contact with water, or by heating a mixture of 2 parts of acetate of soda, 2 of caustic potash, and 3 of powdered quicklime. It is inodorous and tasteless, and its feebly luminous flame deprives it of all value as an illuminating agent. This gas is a compound of 2 atoms of carbon and 4 of hydrogen (C_2H_4).

Marsh Miasma. The infectious vapour which rises from certain marshes and marshy soils, and which tends to produce intermittent and remittent fevers.

Marsh's Apparatus. An apparatus for the detection of arsenic. When a jet of pure hydrogen gas is inflamed, and a surface of

MARSHAL

white porcelain held in the flame, there is no metallic deposit; but if the hydrogen contains a trace of arsenic, a steel-grey deposit of metallic arsenic is observed surrounded by a black ring of the suboxide. This test was first suggested in 1836 by Mr. Marsh of Woolwich, who at the same time described a convenient apparatus for the purpose. Antimony may be similarly detected. The requisite precautions in the use of this apparatus are fully detailed by Dr. Taylor in his *Treatise on Poisons*, chap. xxiii.

Marshal (Low Lat. *marescalcus*, Ger. *marschall*, from Old Ger. *mähre*, a horse, and *schalk*, a servant). A title of honour in many European countries, applied to various dignities and high offices. The title of Marshal of England is now hereditary in the family of the dukes of Norfolk. William Fitz-Osborn and Roger de Montgomery are said to have been marshals to William the Conqueror: their successors for some time are not accurately known; but the office was held in 1138, in fee, by the family of Clare, and thence descended to the earls of Pembroke, and thence to Roger de Bigod, earl of Norfolk, who surrendered it to Edward I. After being granted for life, and during pleasure, to several successive marshals, the dignity, with the title of Earl Marshal, was given to Mowbray, afterwards duke of Norfolk; in whose family the dignity subsisted until it reverted to the crown in the reign of Edward IV. Richard III. granted it to his favourite, Howard, duke of Norfolk; after whose death and attainder it passed through many hands, but was by Charles I. granted for life to his descendant, Thomas Howard, earl of Arundel; and finally his grandson, Henry Howard, earl of Norwich, was constituted hereditary earl marshal of England in 1672, with remainder to the issue male of the earl of Arundel aforesaid; in which latter line it now subsists. The earl marshal is eighth in rank among the great officers of state in England. He has the same jurisdiction over the court of chivalry which was formerly exercised by the constable and marshal jointly.

MARSHAL. In Military affairs, an officer of very high rank in the armies of great powers. The history of the title is a little complicated. The commander of the French forces is for the first time styled *marshal of France* under Philip Augustus. The Estates of Blois under Henry III. fixed the number of Marshals of France at four. Louis XIV. raised it at one time to twenty. Napoleon styled them 'Marshals of the Empire.' In 1839 the number of Marshals of France was fixed at six in time of peace, twelve in time of war.

But the *field marshal*, or *maréchal de camp*, at one time, it is thought, superior in rank to the *marshal of France*, became early in French military history his subordinate. *Maréchal de camp* became synonymous with *aide-maréchal*, an inferior functionary, charged with commissariat and encampment duties, and is now the

MARSHAL

title of an officer below the rank of lieutenant-general.

In Germany, the title *field marshal* was borrowed originally from France, and instead of sinking in dignity, has gradually risen. In the Thirty Years' War the commander of an army was styled *general*, the *field marshal* answering to the *quartermaster-general* of modern armies. In the last century the office of field marshal attained its present dignity, next to that of a commander-in-chief, and has been adopted in this sense from German usage by other military nations, ourselves among the number.

Marshal of the King's Household or Knight Marshal. An officer whose business is said to be to hear and determine pleas of the crown, and suits between persons of the king's household and others within the verge. The marshal of the Queen's Bench has the custody of the Queen's Bench prison in Southwark.

Marshalling. In Heraldry, the arrangement and distribution of coats in a shield so as to denote the several matches and alliances of the family. [BLAZONRY.]

Marshalsea. In Law, the court or seat of a marshal. The King's Bench prison, in Southwark, was so called because the marshal of the king's house was wont to sit there, or to keep his prison. The Marshalsea, or Knight Marshal's Court, held pleas of trespasses committed within twelve miles round Whitehall where one, and of debts &c. where both, of the parties belonged to the royal household. It was abolished in 1849.

Marsilea (after Count L. F. Marsigli, founder of the Academy of Sciences, Bologna). The *Marsileaceae* form a natural order of pseudo-ferns, consisting of a few aquatic genera, the chief of which is *Marsilea*, known by its creeping rhizome, and erect long-stalked leaves having two pairs of leaflets disposed in a cross. The spores grow on receptacles which often spring from the rhizome. The Nardoo of the Australian continent is *M. macrospora*.

Marsupials (Lat. marsupium, Gr. *μάρσιον*, a pouch). An order of Implacental Mammiferous quadrupeds, of which the females have a portion of the abdominal integument folded inwards, forming either a depression containing the mammae, or a pouch serving also as a temporary abode for the young; and the males have a corresponding portion of the abdominal integument extended outwards, forming a scrotum or pedunculate bag for the testes. In both sexes, with one exception, two supplementary trochlear bones are developed in the internal pillars of the abdominal rings, and are articulated to the anterior part of the brim of the pelvis, around which bones plays the muscle supporting and compressing the testes in the male, and the mammary glands in the female: the trochlear ossicles, from their connection by means of these muscles with the pouch, are called *marsupial*. The angle of the lower jaw in marsupials is more or less inverted.

The quadrupeds associated together by the common external and osteological characters above defined so far resemble the oviparous

MARSUPIALS

animals that a placenta is not organised, and the chorion of the foetus contracts no adhesion with the parietes of the uterus. The foetus is prematurely born after a gestation of only thirty-eight days, in the great kangaroo, in which it does not exceed an inch in length. It is then received into the pouch, and adheres to the nipple for many months before it quits the pouch. The generative organs themselves, both male and female, offer several striking peculiarities common to all the Marsupials, and by which they differ from the ordinary Mammalia. Cuvier accordingly, in 1816, separated the marsupial from the other unguiculate quadrupeds, to form a distinct group, which he describes as forming with the Monotremes a small collateral chain; all the genera of which, while they are connected together by the peculiarities of the generative system, at the same time correspond in their dentition and diet, some to the Carnivora, others to the Rodentia, and a third tribe to the Edentata. M. de Blainville, in the Tables of the Animal Kingdom which he published in the same year, 1816, constituted a distinct sub-class of Cuvier's 'small collateral chain' of mammals, and gave to the subclass the name of *Didelphes*, in antithesis to that of *Monodelphes*, by which he distinguished the Placental Mammalia.

Many acute and sound-thinking naturalists refused their assent to these views, which, as they were supported by a knowledge of the conformity of organisation of only the generative system in the Marsupials, were unquestionably defective in the evidence essential to enforce conviction. The best arguments for returning to the older views of classification, and for distributing the marsupial genera, according to the affinities indicated by their dental and locomotive systems, among the different orders of the Placental Mammalia, were advanced by Mr. Bennett, the accomplished author of *The Gardens and Menageries of the Zoological Society delineated* (vol. i. p. 266); and these have been repeated with approbation, and adopted by later classifiers, as Mr. Swainson.

The discovery of the true affinities of the Marsupialia could only flow from an insight into their whole organisation; and the question which Mr. Bennett proposes, 'with reference to the genus *Phascolumys*, 'What is there of importance in the structure of the wombat, except this solitary character of the marsupium, to separate it from the Rodent order?'—a question which he might, in 1831, have asked with equal force in reference to any other marsupial genus—could only be answered satisfactorily by the anatomist who had submitted the Marsupialia in question to a thorough dissection.

Although the Marsupials present modifications of the dental system corresponding with the carnivorous, omnivorous, and herbivorous types, yet they agree with each other, and differ from the analogous Placental Mammalia in having four instead of three true molars, i.e. four molars which are not displaced and succeeded by others, in the vertical direction.

MARSUPIALS

Marsupials never have more than three premolars. In the locomotive organs it is true that we see some of the Marsupials having a hinder thumb, like the Placental *Quadrumanus*; others are digitigrade, with falcate claws, like the Placental *Felis*; a third, as the wombat, has the feet adapted for burrowing; a fourth, like the *Cheironectes*, is aquatic, and has webbed feet; yet all these Marsupials agree with each other in having a rotatory movement of the hind foot, analogous to the pronation and supination, which, in the placental quadrupeds, are limited, when enjoyed at all, to the fore feet; and they manifest, moreover, a peculiar modification of the muscles of the hind leg and foot, in relation to these rotatory movements. In those Marsupials, as the kangaroos, potoroos, and perameles, in which the offices of support and locomotion are devolved exclusively or in great part upon the hind legs, these are strengthened at the expense of the loss of the rotatory movements of the feet; but in the enormous development of the two outer toes, and the conversion of the two inner ones into unguiculate appendages, useful only in cleansing the fur, these Marsupials differ from all Placentals, whilst the same peculiar condition of the toes may be traced through the Pedimanous group of Marsupials. Thus the locomotive organs, notwithstanding their adaptation to different kinds of progression, testify to the unity of the marsupial group in the two remarkable peculiarities of structure above cited.

The vascular system gives evidence to the same effect. All the Marsupials present the following peculiarities in the structure of the

heart; viz. the right auricle manifests no trace of either *fossa ovalis* or *annulus ovalis*, and receives the two *venae cavae superiores* by two separate inlets. This generalisation is, however, less urgent in the present question than the preceding, because the modification as regards the separate entry of the superior *vena cava* obtains in a few placental species, as the elephant and certain Rodents; but as the first cited cardiac character is common and peculiar to the Marsupial Mammalia, and as the second, while it is universal in the Marsupials, occurs only as an exceptional condition in the placental series, the arguments which they afford to the unity of the marsupial group cannot be overlooked in a philosophical consideration of the affinities of the Mammalia.

With respect to the nervous system, it has been shown that, in the structure of the brain, the Marsupialia as well as the Monotremata exhibit a close correspondence with the *Ovipara* in the rudimental state of the *corpus callosum*; the difference which the most closely analogous placental species offer in this respect is broadly marked. (Owen 'On the Brain of the Marsupial Animals,' *Phil. Trans.* 1837, p. 89, pl. vi.)

These coincidences in the Marsupialia of important organic modifications of the dental, locomotive, vascular, cerebral, and reproductive systems, establish the fact that they constitute a natural group, inferior on the whole in organisation to the Placental Mammalia.

The following is a tabular view of the subordinate divisions of the Marsupialia regarded as an order of the *Lyencephalous* or *Implacental* subclass of Mammalia:—

Classification of the Marsupialia.

Tribes	Families	Genera	Subgenera
SARCOPHAGA.			
Three kinds of teeth; canines long in both jaws; a simple stomach; no <i>intestinum cæcum</i> .	<i>Dasyuridæ</i> . . .	Thylacoleo . . .	Fossil.
		Plagiulax . . .	
		Microlestes . . .	
Extinct transitional forms		Thylacinus . . .	Fossil.
		Dasyurus . . .	
		Phascogale . . .	
		Phascolotherium . . .	
		Amphitherium? . . .	
ENTOMOPHAGA.			
Three kinds of teeth in both jaws; a simple stomach; a moderately long <i>intestinum cæcum</i> .	<i>Ambulatoria</i> . . .	Myrmecobius.	
	<i>Saltatoria</i> . . .	Chceropus . . .	
		Perameles . . .	
SARCOPHAGA.	<i>Scansoria</i> . . .	Didelphys . . .	Didelphys. Cheironectes.
		Galethylax . . .	Fossil.
		Peratherium . . .	
Anterior incisors large and long in both jaws; canines inconstant; stomach simple, or with a special gland; a very long <i>intestinum cæcum</i> .	<i>Phalangistidæ</i> . . .	Phalangista . . .	Cuscus. Pseudocheirus. Tapoa. Petaurista. Belidia. Acrobata.
		Petaurus . . .	
	<i>Phascolarchidæ</i> . . .	Phascolarctus.	
POEPHAGA.			
Anterior incisors large and long in both jaws; canines present in the upper jaw only, or wanting; a complex stomach; a long <i>intestinum cæcum</i> .	<i>Macropodidæ</i> . . .	Hypsiprymnus . . .	
		Macropus . . .	
RHIZOPHAGA.			
Two scalpriform incisors in both jaws; no canines; stomach with a special gland; <i>cæcum</i> short, wide, with a vermiform appendage.	<i>Phascalomysidæ</i> . . .	Phascalomys . . .	Fossil.
		Diprotodon . . .	
		Nototherium . . .	

MARTELLO TOWERS

With the exception of one genus, *Didelphys*, which is American, and another genus, *Cuscus*, which is Malayan, all the known existing Marsupials belong to Australia, Tasmania, and New Guinea.

Martello Towers. The name given to the circular buildings of masonry erected along different parts of the British coasts at the commencement of the present century, as a defence against the meditated invasion of Napoleon. The name is usually supposed to be derived from a fort in Mortella (Myrtle) Bay, Corsica, which, after a determined resistance, was at last captured by the British in 1794. These towers are provided with vaulted roofs, and consist of two stories—the lower for the reception of stores; the upper, which is shell-proof, for the casement of troops; and the wall of the building terminates in a parapet, extended to secure the men in working the guns. These are mounted on traversing platforms, so as to be fired in any direction. In many places of England these towers were dismantled, but lately several of them have received a new and more powerful armament.

Marten (Lat. *martes*). A genus of digitigrade carnivorous Mammalia, of which the common and pine martens (*M. foina* and *abietum*) and the sable (*M. zibellina*) form well-known examples; their fur is an important article of commerce in the Russian empire.

Martial Ethiops. An old Pharmaceutical name of black oxide of iron.

Martial Regulus. Metallic antimony, obtained by decomposing sulphide of antimony by means of iron.

Martin. [HIRUNDO.]

Martin's Shells. In Artillery, cast-iron spherical shells, lined with a coating of loam and cow-hair, and filled with molten iron. Upon the shell striking a vessel, it is broken by the impact of the molten metal.

Martinet. A cant phrase for a severe military disciplinarian; probably derived from a certain Colonel Martinet, who served in the French army under Louis XIV., who was the inventor of a peculiar whip, called by his name, for the purpose of military punishment.

MARTINET. The name of one of the engines of war of the middle ages, probably very similar to the trebuchet.

Martingale. In Naval affairs, a rope leading downwards from the jib-boom end, to keep the jib-boom down against the force of the sail and stay.

In the Manège, the term *martingale* is applied to a thong of leather fastened at the end of the girths under the belly of a horse, and at the other end to the musrol, passing between the legs to keep him from rearing.

Martite. A variety of peroxide of iron, found in iron-black octahedral crystals on the Puy-de-Dôme in Auvergne.

Martlet. In Heraldry, a fanciful bird, shaped like a martin or swallow, but depicted with short tufts of feathers in the place of legs.

MASONRY

It is the difference or distinction of a fourth son.

Martnets. Small ropes attached to the leeches of sails to facilitate furling.

Martyr (Gr. *μάρτυς*, *μάρτυρος*, witness). When the members of the Christian church were subjected to persecution under the Roman emperors, the persons accused were questioned as to their belief; and, in undergoing punishments and death, were said to bear witness (*μαρτυρία*) of their Master before the world. A distinction was also made between those who, as boldly asserting their belief, yet not being visited with extreme punishment, were called *confessors*, and those who by suffering death were said to obtain the crown of martyrdom; and thus the term *martyr*, in its ordinary signification, denotes a person who suffers death or persecution on account of his belief.

Martyrology (Gr. *μάρτυς*, and *λόγος*). The name given to that department of ecclesiastical history which relates to the acts and death of martyrs. It also signifies a calendar or register kept in religious houses, wherein were inserted the names and donations of their benefactors, and the days of their death. As specimens of this species of works, we may mention the celebrated *Martyrology* of Eusebius, now lost; and Fox's *Book of Martyrs*, the record of the sufferings of the English reformers. Many of the accounts in the early martyrologies are purely fabulous. (Ruinart's *Acta Martyrum*; Baronii, *Martyrologium Romanum*; Middleton's *Free Inquiry*.) Gallonius' *De Sanctorum Martyrum Cruciatibus* is a book which has had great popularity on the Continent.

Marts. [THOR.]

Mascagn. A native hydrous sulphate of ammonia, found in the fissures of the lavas of Etna, Vesuvius, and the Lipari Isles. Named after its discoverer, Professor Mascagni.

Masole. In Heraldry, a bearing in the form of a lozenge perforated; supposed to represent the meshes of a net.

Masked Battery. In Artillery, a battery concealed from the enemy's view.

Masonry (Fr. *mçonnerie*). The science of combining and joining stones for the formation of walls, and other parts, in the construction of buildings. The science when applied to the construction of domes, groins, and circular arches, is difficult and complicated, depending upon a thorough knowledge of descriptive geometry. Hence the explanation of the various methods of obtaining the requisite lines for the artificer would require an amount of space and a number of diagrams that cannot here be devoted to the subject; but the reader who may desire to become acquainted with this branch of the subject is referred to Rondelet, *Traité Théorique et Pratique de l'Art de Bâtir* (Paris 1829 and 1830, 4to.). Vitruvius mentions several kinds of masonry among the ancients, which were distinguished from each other by the different methods of arranging the stones. The principal are: 1. The *reticulatum*, which

MASORA

is arranged in diagonal courses, like the meshes of a net; whence its name. 2. The *incertum*, wherein the rising courses are so laid, without any certain sizes of the stones, as that the vertical joint above always falls over the middle of the joint below; the appearance of this work is not so pleasing as that of the first, but the work itself is stronger. 3. The *isodolum*, in which all the courses are of equal height, as its name imports. 4. The *pseudisodolum*, which received its name from the courses being unequal in height. 5. The *emplectum*, in which the faces of the work were wrought, and the centre of the wall filled up with rubble work, in which species of masonry the Greeks employed *diatoni*, or bond stones, running in one piece through the thickness of the wall to tie it together. The first principles to be attended to in building stone walls are, that the vertical joints in any course should not fall over the vertical joints of the course immediately below it; and that where the thickness of the wall consists of two or more pieces of stone, bond stones, or blocks which run through the whole wall transversally, if possible in one piece, should be introduced as frequently as possible for the purpose of binding the whole mass together. The different species of masonry now in use may be reduced to five: 1. Bond masonry, *la pierre de taille*, wherein the stones of each succeeding course are laid so that the joint that mounts and separates two stones always falls directly over the middle of the stone below. 2. Coursed masonry, called by the French *maçons moillon emillé*, in which the rubble masonry is inserted in joints whose bond is carefully broken, and which has all the courses of the same height. 3. Rubble masonry, known by the French *maçons* as the ordinary *moillon* masonry, which consists of rubble masonry, of small dimensions, laid without much reference to bond. 4. The masonry known on the Continent by the name of *maçonnerie de libage*, which consists in the employment of large stones also, without regard to bond, in the horizontal direction at least. 5. The masonry of *brickwork*, where the bodies and projections of stone enclose square panels or spaces formed of brick.

Masora. A critical work among the Jews, containing remarks on the verses, words, letters, and vowel-points of the Hebrew text of the Bible. As the sacred books were originally written without any breaks or divisions into chapters or verses or even words, the Jews found it necessary to establish a canon to fix and ascertain the reading of the Hebrew text. This rule or canon is designated *Masora*, or tradition, in which the verses, letters, words, &c. are all numbered; and by this means the slightest variations can be detected. The Jewish rabbis who drew up this work are styled *Masorites*. [BIBLICAL HISTORY, &c.]

Masque or (a word of doubtful origin). A species of drama, which originated from the custom (in processions and other solemn occasions) of introducing personages in

MASS

mask to represent imaginary characters. Many of these characters, even in the religious shows of Italy, &c., were of a grotesque description, and the performance was often intermixed with dancing and buffonery. By degrees, in land, something of a dramatic character was added to these exhibitions. At first, as in the well-known progresses of Queen Elizabeth, monologues or dialogues in verse were put into the mouths of the masked performers; and in the reign of James I. they had ripened into regular dramatic performances: sometimes, as in the *Tempest* of Shakespeare, introduced by way of interlude in regular plays; at other times acted as separate pieces, with much machinery and decoration. Ben Jonson was the first, and indeed almost the only, classical English writer (with the exception of Milton, in the solitary and noble specimen of *Comus*) who devoted much labour and taste to this department of the drama. His masques were represented at court: the queen of James I., and after her the accomplished Henrietta Maria, did not disdain to take part, at least as silent dramatis personae, in some of these pageants. The taste for them died away in the reign of Charles I.; and after the interruption given to the progress of dramatic art and literature by the civil wars, they were not again brought into fashion.

Masquerade. An amusement practised in almost every civilised country of modern times, consisting of a ball and other festivities, in which only those who are masked or disguised can participate. This species of amusement had its origin in Italy, where, according to Hall's *Chronicle*, they had become fashionable so early as in the beginning of the sixteenth century. Of its introduction into England, Hall thus speaks: 'On the date of the Epiphaine, at night (A. D. 1612-13), the king (Henry VIII.) with eleven others were disguised after the manner of Italie, called a maske, a thing not seen afore in England; they were appareled in garments long and brode, wrought all with golde, with visers and cappes of golde; and after the banquet doen, these maskers came in with the six gentlemen disguised in silk' (in all probability the *domino* of more recent times), 'burynge staffe torches, and desired the ladies to daunce: some were content; and some that knew the fashion of it refused, because it was not a thing commonly seen. And after thei daunced and commoned together, as the fashion of the maskes is, thei toke their leave and departed, and so did the quene and all the ladies.' The invention of masquerades is ascribed to Granacci, who died in 1543.

Mass (Low Lat. *missa*). The name by which Roman Catholics designate the celebration of the Lord's Supper after the forms of the Roman church. The term is commonly derived from the phrase, 'Ite, missa est concio' (i. e. *Go, the assembly is dissolved*); by which the priest, in the primitive ages, signified to the catechumens that all that part of the service of the church was concluded which it was allowed to all

MASS

believers indiscriminately to attend. This derivation has, however, been questioned by Mr. King, in his work on *The Gnostics and their Remains*. The communion of the eucharist was extended only to the higher class, the *fideles*, who had completed the period of initiation and instruction; and after the pronouncement of these words, the offering of the body and blood was made. It was to this offering itself that the term *missa* came to be applied. The service of the mass, as it is still retained throughout Catholic countries, was the work of Gregory I. in the sixth century. It consists of three parts: the offertorium, or offering of the elements upon the altar; the consecration, by which they are supposed to undergo the transubstantiation into the real body and blood of Christ; and the sumption, or actual participation in them by the communicants. These ceremonies are accompanied by the recitation of various prayers; and the priests go through numerous evolutions, which are supposed to represent the circumstances attending the Passion. High mass is the performance of this service accompanied with music.

Mass. In the Fine Arts, a large quantity of matter of light or shade. It is generally applied in painting to light and shade brought upon objects proper for their reception, and grouped or arranged so as to give repose and pleasing variety both of one and the other without being scattered.

Mass (Lat. *massa*, Ger. *masse*). In Mechanics, this term is synonymous with *quantity of matter*. At the same distance from the earth's centre, *mass is directly proportional to weight*, since we must assume that the force of gravity then acts equally on all equal particles of matter. At different distances from the earth's centre, however, weight varies whilst mass remains unaltered, so that we must regard *weight* as the *product of mass into the force of gravity*. The mass of a homogeneous body is proportional to its volume; and the mass of the unit of volume being termed its density, we may define mass as the product of volume and density.

Masseter (Gr. *μασητήρ*, a *chewer*). A short thick muscle which raises the lower jaw, and assists in moving it backwards and forwards in the act of chewing.

Massicot. Yellow oxide of lead.

Mast (Ger.; Fr. *mât*). A long piece or system of pieces of timber, placed nearly perpendicularly to the keelson of a vessel to support the yards or gaffs on which the sails are extended. When a mast is one entire piece, it is called a *pole-mast*; but in all large vessels it is composed of several lengths, called *lower*, *top*, and *top-gallant* masts—sometimes a fourth, called a *royal* mast, which, however, is usually in one piece with the top-gallant mast.

The method of supporting each mast on the one next below it is peculiar. On the sides of the lower mast, some feet below the head, are placed cheeks: on these are fixed horizontally two short pieces of wood, fore and aft, called *trestle trees*. Across these at right angles are

MASTER

laid, before and abaft the mast, two or more longer and lighter pieces, called *cross trees*, which give the name to the entire system. On the masthead itself is a *cap*.

The topmast, being placed up and down the fore side of the lower mast, is *swayed up* between the trestle trees, and through the round or foremost hole in the cap, by means of the lifts. When raised so high that the *heel* of the topmast is just above the surface of the cross trees, a piece of iron, called the *mast-fid*, is put through a hole formed in the heel for that purpose; and on this fid, of which the ends are supported on the trestle trees, the topmast rests. When fidded, the topmast is *stayed*, and the rigging or shrouds *set up to the dead eyes* in the ends of the cross trees or top. These dead eyes pull from the lower rigging below, and thus the cross trees of the top serve merely to extend the rigging of the topmast. The topgallant is supported in the same manner on the topmast, its shrouds passing through holes in the ends of the topmast cross trees down to the top below. When the mast is to be taken down, it is first raised to relieve the fid; which being drawn out, the mast is lowered.

The masts are supported by a strong rope, leading forward, called the *stay*; by others, leading aft on each side of the ship, called, in general, *backstays*; and by others abreast, called *shrouds*.

Large lower masts are composed of several pieces, about a foot square, with rounded segmental lengths on the outside, and the whole encircled at intervals by hoops. Hollow masts of iron are likewise now successfully employed; being considered not less strong than wood, and much lighter.

The *main-mast* is near the middle of the vessel, if there be three masts, otherwise at the after part. The *fore-mast* is that which is nearest the fore part, and the *mizen-mast* is abaft the mainmast.

The old rule for the length of the main lower mast is to take $\frac{1}{4}$ the sum of the length of the lower deck and extreme breadth: the fore-mast is $\frac{2}{3}$ ths of the main-mast, the mizen-mast considerably smaller. The topmast is about $\frac{2}{3}$ ths of the lower mast. These rules, as well as others for the thicknesses, &c., are merely for convenience, based on no mechanical principle, and are by no means strictly followed.

Master (Lat. *magister*). A title frequent among the Romans: as *magister equitum* (master of the horse, the lieutenant or second in command to a dictator), *magister bibendi*, &c. *Magister militum* (master of the soldiers, or of military affairs) was a title under the later Roman emperors. *Grand master*, in modern times, is the common title of the chief of the orders of knighthood, and of some fraternities, as the Freemasons. The eldest sons of some noble landed proprietors are designated as masters in Scotland; as the master of Gray, master of Douglas, &c.

MASTER. In the Universities, a degree in arts; the most ancient of all the academical titles. In the university of Paris, where this, as

MASTER.

well as the other learned distinctions, appears to have originated, it was originally a mere title, belonging to those who taught in the schools (*magistri*, *doctores*). Thus every master was, of necessity, a lecturer. In process of time (and probably about the middle of the thirteenth century the title became a degree, attainable by all after a certain amount of residence and proficiency; while the duty of lecturing was confined only to a certain number of masters, termed *regents*. About the same period the separation of the degrees of master and doctor took place. In the English universities, the degree of master of arts follows that of bachelor, and is the highest in the faculty of arts, which is subordinate to that of divinity. Elsewhere the faculty of arts is synonymous with that of philosophy, in which the degree of doctorate is conferred, superior to that of master.

MASTER, otherwise called **CAPTAIN**. In Commercial Navigation, the person intrusted with the care and navigation of a ship. His duties are very important. In some countries no one can be appointed to this office who has not been declared fit to fill it by a legally constituted board; but in this country the owners, except in the case of large vessels, are left to their own discretion as to the skill and honesty of the master; and although he is bound to make good any damage that may happen to the ship and cargo by his negligence or unskilfulness, he cannot be punished as a criminal for mere incompetence. Under the Mercantile Marine Act, however, the Board of Trade grants certificates of qualification to masters of vessels, and possesses the power of withdrawing them in case of a want of skill being evinced. Large vessels may only be commanded by certificated masters, and even in small vessels the certificated man naturally has the preference.

MASTER. In the Royal Navy, the officer who has the charge of the navigation of the ship, with other duties: he ranks with, but after, a lieutenant. On completing certain long service the master becomes staff-commander and staff-captain, ranking similarly with commander and captain. The class of masters is gradually dying out, their place being intended to be hereafter taken by *navigating lieutenants*, i.e. lieutenants who have passed a special examination in the art of navigation.

Master Attendant. The officer next in rank to the superintendent of a royal dockyard, and usually a commander in the navy.

Master of the Ceremonies. An officer attached to all European courts, whose duty consists in regulating all matters of etiquette and state ceremony. [*CEREMONIES*, &c.] The name is also applied to anyone appointed by general consent to preside over the arrangements of a public ball.

Master Gunner. A warrant officer, selected from the non-commissioned officers of artillery, whose duty is to take charge of guns, ammunition stores, &c. in fortresses.

Master of the Horse. The third great officer in the British court. [*HOUSEHOLD*.]

MASTOTHECA

Master of the Household. An officer employed under the treasurer of the household to survey accounts.

Master of the Robes. An officer of the royal household, in the lord chamberlain's department.

Master of the Rolls. [*CHANCERY*.]

Master Singers. A class of poets in Germany during the fifteenth and part of the sixteenth century. They were confined to a few imperial towns, and their chief seat was the city of Nuremberg. They were generally of burgher extraction; and formed regular corporations, into which proficientes were admitted by the ordinary course of apprenticeship. Their poetry (generally confined to devotional or scriptural pieces, legendary tales, with some admixture of satire and of amatory lyrics) was subjected to a peculiar and pedantic code of laws; and a board of judges (styled *marker*) assembled to hear the poems recited, and mark the faults which might be committed in either particular: he who had the fewest faults received the prize. Hans Sachs, the famous cobbler of Nuremberg, was a member of these societies; although his genius was of too independent a character to submit to the trammels of their poetical regulations.

Masters. In the Superior Courts of Law and Equity in England, subordinate officers of those courts, whose duties chiefly relate to the taxation of costs and decision of minor questions between suitors. The *masters in ordinary*, commonly called *masters in chancery*, whose functions were of a more important character, were abolished in 1853 (15 & 16 Vict. c. 80).

Masters in Chancery. [*MASTERS*.]

Master-at-Arms. A petty officer of the navy, who is the head of the police of the ship: his assistants are called ship's corporals.

Masterwort. *Imperatoria Ostruthium*.

Mastic. A resin which exudes from the *Pistacia Lentiscus*. Its chief use is in varnishes. It is often erroneously called *gum-mastic*.

Masticatories. Medicines which tend to increase the flow of saliva. [*SIALOGOGUES*.]

Masticoin. That part of mastic which is insoluble in alcohol; it has some of the characters of caoutchouc. The part of mastic soluble in alcohol has been termed *Masticic acid*.

Mastitis (Gr. *μαστός*, the breast). Inflammation of the breast in women; it commonly terminates in suppuration.

Mastodon (Gr. *μαστός*, and *δόνς*, tooth). A genus of extinct fossil quadrupeds allied to the elephant; so called from the conical projections upon the surfaces of the molar teeth. It is divided by Dr. Falconer into the sections *Trilophodon* and *Tetralophodon*.

Mastoid Processes (Gr. *μαστοειδής*). Certain nipple-like protuberances of the bones.

Mastotheca (Gr. *μαστός*, and *θήκη*, a receptacle). A name sometimes applied to the abdominal pouch of the marsupial animals.

MATADOR

Matador (Span. *a slayer*). The name given to the man whose office it is to give the deathblow to the bulls wounded in the Spanish bullfights.

Match (a word of doubtful origin). In Gunnery, a material employed in firing mines, &c. Before the invention of locks, small arms were fired by means of match. *Slow match* consists merely of hempen rope loosely twisted and dipped in a solution of saltpetre and lime-water. It burns at the rate of one yard in three hours. *Quick match* is merely cotton coated with a composition of meal powder, gum, and water. When not confined, it burns at the rate of one yard in thirteen seconds. [LUCIFER.]

Match Boarding. This term is applied to wall linings executed in boarding beaded on the edge, and with a groove in the plank that carries the bead and a tongue on the edge of that which follows it. Sometimes this style of work is called *matched* and *beaded boarding*; sometimes the beading on the edge is dispensed with, and the boarding presents joints that are simply mortise-joints.

Matchlock. A hand firearm, the charge of powder in which is lighted by means of MATCH.

Mate (Dutch *maet*, Old High Ger. *gāmazi*). In a Merchant Ship, the deputy of the master, taking in his absence the command. There are sometimes only one, and sometimes two, three, or four mates in a merchantman, according to her size, denominated *first*, *second*, *third*, &c. mates. The law, however, recognises only two descriptions of persons in a merchantman—the master and mariners, the mates being included in the latter, and the captain being responsible for their proceedings.

In the Royal Navy, the term *mate* is now limited to the assistants of certain warrant officers, as boatswain's mate, gunner's mate, &c. Formerly it was the distinctive title of the next grade to lieutenant, now called sub-lieutenant. There were also the master's mate, now second master; and surgeon's mate, now assistant-surgeon.

Maté. The South American name of the *Ilex paraguayensis*, a species distinguishable by its smooth ovate-lanceolate, unequally-serrated leaves, by much-branched racemes of flowers, the subdivisions of which are somewhat umbellate, and by the slightly hairy calyx of its flowers. The Maté is of the same importance in the domestic economy of South America as the Chinese tea is in that of this country, and it is calculated that its consumption in that continent amounts to about 8,000,000 lbs. annually. It has been in use for about a century and a half, the practice having been adopted from the aboriginal people. The leaves are prepared by drying and roasting—not in the manner of Chinese teas; but large branches are cut off the plants and placed on hurdles over a wood fire until sufficiently roasted; the branches are then placed on a hard floor and beaten with sticks; the dried leaves are thus

MATERIALISM

knocked off and reduced to a powder, which is collected, and made into packages, ready for use. There are three sorts known in the South American markets—the Caa-Cuya, which consists of the half-expanded leaf-buds; the Caa-Miri, the leaf torn from its midrib and veins, without roasting; and the Caa-Guaza or Yerva de Palos of the Spaniards, the whole leaf with the petioles and small branches roasted.

Maté is prepared for drinking by putting a small quantity, about a teaspoonful, into a gourd or cup, with sugar; the drinking tube is then inserted, and boiling water poured on; when sufficiently cool, the infusion is sucked up through the tube. It has an agreeable slightly aromatic odour, is rather bitter and restorative, and very refreshing. It acts as a slight aperient and diuretic, and if too largely indulged in, debilitates the nervous system. It contains the active principle—theine—of tea and coffee.

Materia Hermaphrodita. A term applied by Boerhaave to a peculiar substance soluble both in alcohol and water, and contained in vegetable extracts. Scheele called it *Materia saponacea*. It is the extractive or humine of later chemists.

Materia Medica (Lat.). This term embraces the various substances, natural and artificial, which are used in the cure of disease, and which are usually called *medicines*. They are frequently arranged into classes dependent upon their virtues or effects, or upon their constituent parts; but perhaps the most convenient arrangement is the alphabetical.

Material, Raw or Rude. In Political Economy, a term used to imply such products of human labour as require further manipulation in order to make them available for use or consumption. In the progress of a nation towards opulence larger quantities of raw material are imported, in order that they may receive the finish of manufacture. Thus, this country purchases silk from Italy and China, wool from Australia, alpaca from Eastern South America, cotton from all parts of the world, hemp and flax from Russia, and exports goods manufactured from these materials. The term appears to have been originally employed by Adam Smith.

Materialism. That metaphysical theory which is founded on the hypothesis that all existence may be resolved into a modification of matter, including, of course, the conscious subject. The most celebrated materialists were, among the ancients, Democritus and his later disciples, Epicurus and his sect, to whom may be added, though in a somewhat different sense, the Stoics; among the moderns, Gassendi, Hobbes, Hartley, and Priestley. Most schemes of materialism rest on the assumption that all that is real in nature consists in the minute particles from the juxtaposition of which all sensible objects arise. This is what is variously designated as the *atomic*, the *mechanical*, or the *mechanico-corpuscular* theory, and has met with supporters chiefly in France.

MATHEMATICI

Among ourselves, in very recent times, Dr. Thomas Brown maintained that part of this system which relates to physical phenomena, though he has combated, with great subtlety and ingenuity, the portion of it which includes the nature of the mind itself. (Compare secs. v.-ix. with secs. xii.-xiv. See also Priestley's *Disquisitions on Matter and Spirit*, 1777; and his *Three Dissertations on the Doctrines of Materialism and Philosophical Necessity*; also Price's *Letters on Materialism and Philosophical Necessity*.) Since that period, the term *materialism* seems itself to have fallen into disfavour, although the doctrines of the Encyclopedic school of philosophers in France (Cabanis, Condillac, and others), of similar tendency, still find their supporters in various altered forms. [METAPHYSICS.]

Mathematici. [GENETELIACI.]

Mathematics (Gr. μαθηματικός, from μάθημα, a lesson). The science which investigates the properties of number and space. It is sometimes divided into *pure* and *mixed* or *applied mathematics*. The distinction, however, is vague and useless. Whenever, according to it, the properties of matter enter into consideration, as in mechanics, mathematics become *mixed*. The principal branches of pure mathematics are arithmetic, algebra, geometry (pure and algebraic), differential and integral calculus, calculus of differences, of functions, of variations, of operations, and of probabilities.

Matteo (its name in Peru). The dried leaves of *Artanthe elongata* of some botanists, *Piper angustifolium* of others, imported from Peru; they are from two to eight inches long, veined and tessellated on the upper surface, downy beneath, with an aromatic astringent taste, and an agreeable odour. They contain an essential oil, and a bitter principle which has been called *maticin*, and are tonic and stimulant.

Matins. In the Roman Catholic church, the earliest of the canonical hours of prayer. [HOURS.]

Matlockite. An oxy-chloride of lead, found in an old mine at Matlock in Derbyshire.

Matrass. A chemical vessel employed in sublimations, and in digesting solutions in a sand heat. It is superseded in the modern laboratory by a flask.

Matriculation (from Lat. mater, mother). This word is used in universities on the old model to express the act of admitting a member. Matriculation, in the English universities, is contemporary with admission into one of the colleges or halls of which the university is composed.

Matrix. Any rectangular arrangement of symbols.

Thus

$$\begin{array}{ccc} a_1 & b_1 & c_1 & d_1 \\ a_2 & b_2 & c_2 & d_2 \\ a_3 & b_3 & c_3 & d_3 \end{array}$$

is a rectangular matrix consisting of four columns and three lines or rows. When there

MATTER

are an equal number of rows and columns the matrix is said to be *square*, and that number expresses the order of the matrix. In all cases the symbols, which may denote either quantities or operations, are called the *constituents* of the matrix, and in a square matrix the line joining the upper left to the lower right hand corner is called the *principal diagonal* of the matrix, the constituents situated upon it being distinguished as *principal constituents*. Any two constituents of a square matrix which are symmetrically placed with respect to the principal diagonal are said to be *conjugate*.

The *inverse* or *reciprocal* of a given square matrix is a matrix, of the same order, whose constituents are, respectively, the coefficients of the corresponding constituents in the determinant formed from the given matrix. [DETERMINANT.] The constituents of the reciprocal matrix, therefore, are the several first minors of the determinant in question, and are consequently themselves determinants of the next lower order.

A square matrix is said to be *symmetrical* when the conjugate constituents are equal; if besides this the constituents are all equal which are situated in the diagonal bands transverse to the axis of symmetry, the matrix is said to be *persymmetrical*. An ordinary addition table is an example of such a matrix.

MATRIX. In Metallurgy, the stony substance in which crystalline minerals and metals are embedded is frequently termed their *matrix* or *gangue*.

In Die-sinking, the *matrix* is the indented engraving or mould from which impressions are taken in relief.

Type-founders apply the term *matrix* to the iron moulds in which the letters are cast.

Matter (Lat. materies). Substance. That part of the universe which is neither mind nor force. We know nothing of the essential or intimate nature of matter, and are only acquainted with its existence through its *sensible properties*. The following are generally considered as the essential properties of matter:—

1. *Divisibility*, or the property which every known substance possesses of being separable into parts, and these again into smaller parts, and so on until the parts become inappreciable to our senses. Although no definite limit can be assigned to this subdivision, there is reason to believe that matter is not infinitely divisible, but that each kind of matter consists of ultimate particles or atoms, or groups of such atoms, which are incapable of being further subdivided.

2. *Impenetrability*, or a resistance exerted by every body to the occupation of its place by another. No two bodies can simultaneously occupy the same place.

3. *Porosity*, or the separation of the particles or atoms from each other by intervals or pores. Every substance with which we are acquainted is more or less porous.

4. *Compressibility*, or the property in virtue

of which the volume of every body may be contracted into smaller dimensions.

Among the essential properties of matter may also be included *extension* and *figure*; but these belong also to space, and form the subject of geometry.

The contingent properties of matter are *mobility* and *weight*. Matter in every form is capable of being moved from one place to another; and every substance is subject to the attraction of gravitation. But motion has reference to space, and weight to the attraction of other matter.

The above are the general properties of matter, upon which physical investigations depend. There are, however, various other qualities belonging to particular substances, or to matter in particular states, the consideration of which is important in mechanical philosophy. Among these the principal are ELASTICITY, FLUIDITY, HARDNESS, RIGIDITY, SOLIDITY, for which see the respective terms.

Matura Diamond. A kind of Zircon used by the native jewellers of Ceylon, by whom the pink stones are sold for rubies.

Mauilite. A variety of Labrador Felspar, found in Maui, one of the Sandwich Islands.

Maundy Thursday. The Thursday preceding Easter, on which the sovereign of England distributes alms to a certain number of poor persons at Whitehall; so named, perhaps, from the maunds or baskets in which the gifts were formerly contained. This custom is of very great antiquity; and according to Ducange it derives its origin from St. Augustine. Maundy Thursday is also called Shere Thursday. (*Nares' Glossary*; *Fosbrooke's Encyc. of Antiquities*, p. 702.)

Maur, St., Congregation of. A learned body of religious of the Benedictine order; so called from a village near Paris, where they were established in 1618. On the request of Louis XIII., Gregory XV. gave this order his approval by an apostolical brief, dated 17th of May, 1621; and it obtained new privileges from Urban VIII., by a bull dated January 21, 1627. The fame of this body attracted the attention of many other religious orders, several of which were induced to submit to its rules; and at last it numbered upwards of a hundred religious houses. The literary world owes to them a series of very valuable editions of ancient Greek authors, chiefly fathers, during the seventeenth century. Among the most eminent of its members during that period may be mentioned Jean Mabillon, Thierri Ruinart, Hugh Menard, and Bernard de Montfaucon.

Mausoleum (Lat.). A sepulchral building erected to the memory of some celebrated character, so called from Mausolus, king of Caria, to whose memory a monument of this character was raised by his wife, Artemisia, about the year 353 a.c., whence all sepulchral monuments of importance have obtained the name of mausolæa. From its magnificence this monument was reckoned one of the seven won-

ders of the world. It has lately been the object of the care of the British government, who have sent an expedition, under the direction of Mr. Newton, for the purpose of rescuing the relics of it from the ravages of time and the carelessness of the inhabitants of the country; the marbles from it are at present in the British Museum, and they confirm the reports of the ancients as to the beauty and skill of the monument. According to Pliny, it was one hundred and eleven feet in circumference, and one hundred and forty feet high; it is said to have been encompassed by thirty-six columns, and to have been profusely adorned with sculpture. (*Edinburgh Review*, Oct. 1862, p. 461 &c.)

Mauve (from Lat. *malva*, a mallow, the petals of which have purple markings). A purple dye obtained from aniline and from benzol, two of the constituents of coal-tar. This colouring matter was discovered in 1861 by Mr. Perkin, and is made by oxidising aniline with chromic acid. Heated together, sulphate of aniline and bichromate of potash yield a precipitate which is crude mauve. This is dissolved in alcohol and the solution evaporated, the pure dye is obtained. Silk and wool readily take up mauve dye, while cotton and calicoes require mordanting with tannin or a basic lead salt.

Maxilla (Lat. a jaw). In Anatomy, this term is applied to the bones supporting the teeth of both jaws. In Zoology, it is restricted to the upper jaw in Mammalia, and to the inferior pair of horizontal jaws in articulate animals.

Maxima and Minima. In Mathematics, a variable quantity or function is said to be a maximum or minimum when its numerical value is greater or less than any immediately adjacent values, that is to say when the smallest change in the values of one or more of the independent variables causes a diminution or augmentation in the value of the function. Thus a function may have several maxima or minima; the greatest of the former is called a *maximum maximorum*, and the least of the latter a *minimum minimorum*. The determination of maxima and minima is fully explained in all good treatises on the differential calculus and the calculus of variations. The methods to be pursued vary, of course, with the nature of the function to be investigated, and in some cases questions of a peculiarly delicate nature present themselves for solution. We must here limit ourselves to the simplest and most frequently occurring case, where the maxima and minima of an explicit function, y , of a single independent variable, x , are required. To determine these it is necessary to ascertain, in the first place, what values of x cause $\frac{dy}{dx}$ to change sign, by

passing through 0 or ∞ . This done, the effect of each such critical value of x upon the differential coefficients of higher order must be examined. If the first of these which does not vanish for the critical value under examina-

tion be of an *odd* order, that value will not correspond to either a maximum or minimum of y ; if of even order, however, the function y will be a maximum or minimum according as the differential coefficient in question acquires a negative or a positive value.

The purely geometrical methods of determining maxima and minima are of a far less uniform and systematic character; they have the advantage, however, of being more instructive, inasmuch as they reveal more fully the true origin of the maximum or minimum properties under examination. This has been admirably shown by Steiner in his memoirs on maxima and minima in Crelle's *Journal*, vol. xxiv. To illustrate such methods by a very simple example, let it be required to determine from what point M of a given curve (C) the distance between two given fixed points A and B will appear greatest or least. Since the visual angle $\angle AMB$ is constant for all points M on the circumference of a circle passing through A and B, and is less for all points without this circle and greater for all points within it, the problem will obviously be solved by determining the points of contact, with the given curve (C), of all circles which pass through the fixed points A and B.

May (Lat. *Maius*). The fifth month of our year, but the third of the old Roman calendar. [CALENDAR.]

May Apple. *Podophyllum peltatum*. The leaves are poisonous, and the root cathartic, but the fruit is agreeable and esculent. The rhizomes possess active medicinal properties, on account of which the plant has been cultivated.

May Beetle. [MELOLONTIIDANS.]

May Day. The first of May is usually so called in England, by way of eminence, in commemoration of the festivities which from a very early period were till recently, and in many parts of the country are still observed on that day. In looking at the nature of these rites, it is evident that they are akin to the observances practised in honour of the Latin goddess Flora; but it is impossible to fix with accuracy the precise period at which they were introduced into England. At first the observance of this day appears not to have been peculiar to any class of society. In his *Court of Love* Chaucer says, that on this day 'forth goeth all the court, most and least, to fetch the flowres fresh, and braunch and bloom;' and Henry VIII. and Katherine and all their court partook in the diversion. The *maypole*, which is still visible in many of the English villages, and *Jack in the green* are still relics of this custom. (Grimm's *Deutsche Mythologie*, pp. 448-451.)

May-fly. The popular name of the Nematopterous insects, comprising the genus *Ephemera* and its allies. They live in the larval state for about two years under water, or in wet places; but die frequently a few hours after attaining their highest final stage of metamorphosis.

Mayor (Lat. *major*, meaning the first or senior alderman). The title of the chief municipal officer of a borough, to whom it appears to have been first given by charters granted some time after the Conquest. But the title and office of portreeve or boroughreeve still continued, in some few places to the exclusion of, and in some others in conjunction with, that of mayor, until the passing of the Municipal Reform Bill, 5 & 6 Wm. IV., by which the latter title was applied universally and exclusively to every borough. The chief magistrates of London and Dublin are designated Lord Mayor.

In France, the first municipal officer of each commune, according to a general system established by the law of December 14, 1789, which created municipalities, is styled *maire*. He has one or more *adjuncts* or assessors, according to the population of the commune. The *maire* keeps the registers of births, marriages, &c. of the commune; he acts as a magistrate in the apprehension and commitment of offenders; he has also a judicial power over certain minor offences. He is also the principal agent of the general administration for his commune, and the executive authority to carry into effect the ordinances of the municipal council. The *maire* is now named by the emperor, and his office lasts five years.

Mayor of the Palace (Lat. *major domus regie*). In early French History, the title of the chief officer of state under the Merovingian kings. After the death of Dagobert I., A.D. 638, and in the subsequent decay of the royal authority, these functionaries by degrees usurped almost the entire power of the state. The first of those mayors who exercised this kind of sovereignty was Grimoald, under Sigebert III., king of Austrasia. Pepin, son of Charles Martel, having succeeded his father in the office of mayor of the palace, ascended the throne in 752; after which time the office lost its importance, or was altogether abolished. (Turner, *History of England in the Middle Ages*, vol. i. p. 8.)

Mayorazgo (Span. from Lat. *magistratus*). Strictly, the right possessed by the eldest born in noble families to inherit certain property on condition of transmitting it entire to those possessed of the same right on his decease. Five distinct species of mayorazgo, or right of hereditary succession, are now known in Spanish law. Property held in virtue of the right cannot be alienated or disposed of. The mischievous effects of this strict system of entail on agriculture and national wealth, and on the character of the higher classes of Spain, have been long insisted on by political philosophers. [MAJORAT.]

Mazzinians. In Politics, the extreme party of progress in modern Italy have received this popular appellation, from the name of their most active leader, Joseph Mazzini. This celebrated personage was an advocate in Genoa (his birthplace), when in the year 1830 he became compromised in the revolutionary movements then in progress, was condemned

MEAD

to death *par contumace*, and fled the country. From that time his name is found mixed up in most, with actual participation in many, of the plots which have been formed for revolutionising Italy. Originally a member of the ancient association of the Carbonari, Mazzini seems to have regarded it as ill adapted for the continuance of the struggle in which it had failed in 1820-30, and to have raised up in its stead the recent societies known as *Young Italy* and *Young Europe*, which conducted their operations under his auspices first from Switzerland and afterwards from England. Republicanism and Italian unity were the two objects, at one time deemed equally chimerical, towards which their operations were directed. The part played by Mazzini himself in the Roman affair of 1848 is well known: since his second exile on that occasion, he is believed to have had comparatively little influence in the course of events.

Mead (Gr. μέθυ, Dutch meede). A vinous liquor made by dissolving one part of honey in three of boiling water, flavouring it with spices, and adding a portion of ground malt and a piece of toast dipped in yeast, and suffering the whole to ferment. The Scandinavian mead is flavoured with primrose blossoms. A liquor called by this name formed the ancient and for centuries the favourite beverage of the northern nations.

Meadow. A flat surface under grass, generally on the banks of a river or lake; but so far above the surface of the water as to be considerably drier than marsh land, and, consequently, to produce grass and herbage of a superior quality. The soil of meadow lands, if the term be confined strictly to river-side pastures, is generally alluvial, and more or less mixed with sand; it is kept in a state of fertility by the depositions made on its surface, in consequence of being occasionally overflowed by the adjoining river or lake. The produce of meadows is generally made into hay, which, though not equal in quality to that produced on drier grass lands, is yet superior to what is obtained from marshes.

Water meadows are such as receive generally during the winter months, though occasionally also in the summer time, the waters of an overflowing stream, which, by a suitable arrangement of the land in alternate ridge and furrow, are made to traverse the surface without stagnating anywhere. The result is a rapid and early growth of grass in spring time, which, though not very nutritious, is useful for cows, ewes, and lambs, at a time when green food is not abundant.

Drainage is as necessary for the attainment of a high degree of fertility in water and other meadows, as it is in the case of ordinary pasture and arable land; and the application of manure is then as desirable and profitable. Mr. Lawes' experiments show that ammoniacal manures, as guano, sulphate of ammonia, &c., tend to the development of grasses in meadows; and mineral manures, as phosphates and

MEASURE

the alkalies, tend rather to the development of the clovers and other leguminous plants.

Mean (Fr. moyen). In Mathematics, a quantity whose value, when determined according to some assigned law, is intermediate between those of two or more given quantities. [ARITHMETIC; GEOMETRIC and HARMONIC MEAN.]

Mean Distance. The mean distance of a planet from the sun is equal to its semi-axis major. That of the earth is taken as the unit of most measurements connected with our system.

Mean Sun. To obtain a proper measure of time, an imaginary, or as it is called a *mean sun* is supposed to move uniformly in the celestial equator with the mean velocity of the true sun. A *mean solar day* is the interval between two successive transits of the mean sun over the same meridian. It begins when the mean sun is on the meridian.

Measles (Dutch maeslen, from maese, a spot). A fever accompanied with eruptions. It occurs chiefly in early youth, and is for the most part a trivial malady. The nose and eyes generally become inflamed, and watery discharge follows. The principal danger consists in the occasional complication with inflammation of the lungs (pneumonia). The eruption is of peculiar character, the marks upon the skin having an irregular crescentic form. Measles appear to occur occasionally as an epidemic. It rarely affects the system more than once. The treatment of uncomplicated cases is generally limited to the exhibition of mild aperients and diluent drinks. The complications require energetic treatment, modified by considerations of age and habit and the general character of the attack. [RUBEOLA.]

Measure (Lat. mensura). In Geometry, a magnitude or quantity taken as unit, and employed to express the relations of other magnitudes or quantities of the same kind. Euclid defines the measure of a quantity to be that which, being repeated a certain number of times, becomes equal to the quantity measured. Thus in Arithmetic, the *measure of a number* is any number which divides the given number without leaving a remainder; but this definition rather corresponds to the notion of *aliquot part*.

In a general sense, the term *measure* is applied to that by which anything is compared in respect of quantity. Thus, we have measures of extension, of weight, time, force, resistance, temperature, &c.; in short, of everything of which greater and less can be predicated; and it frequently happens that the unit or measure is not taken in the thing or property which is the immediate subject of consideration, but in something else which depends on it, or is proportional to it. Angular space, for example, is measured by an arc of a circle; time, by the rotation of the earth about its axis, or its revolution about the sun; mechanical force, by the quantity of motion which it imparts to a body; degrees of heat, by the expansion of metals or other substances; muscular strength, by the

MEASURE

resistance of a spring, &c. [ANGLS; CHRONOMETER; GRAVITY; THERMOMETER; DYNAMOMETER, &c.]

By measure, in an absolute sense, is understood the unit or standard by which we measure extension. We have, therefore, measures of length, of superficies, and of volume or capacity; but, as the two latter may be deduced in all cases from the former, it is only necessary to establish a unit, or standard of length. The choice of such a standard, and the different multiples and parts of it taken for the uses of society, form a metrical system, or system of metrology.

Standards of Measure.—As no precise notion can be formed of the magnitude of a line in any other way than by comparing it with another line of a known length, the necessity of having recourse, for the interchange of ideas, to measures not entirely arbitrary, but fixed by nature, and intelligible alike to all mankind, seems to have been perceived in the earliest ages. Hence originated the *foot*, the *cubit*, the *span*, the *hand*, the *fathom*, the *barleycorn*, the *hair's-breadth*, and other denominations of measure, taken from parts of the human body, or from natural objects, which, though not of an absolute and invariable length, have a certain mean value sufficiently definite to answer all the purposes required in a rude state of society. But, as civilisation advanced, the necessity of adopting more precise standards would be felt, and the inadequacy of such measures as the foot, the cubit, &c. (referred only to the human body) to convey accurate notions, would be rendered most apparent in their application to itinerary measures, or the estimation of great distances; where differences of the fundamental measure, of no account when one or two units only are taken into consideration, would amount, by repeated multiplication, to enormous quantities. In order to avoid this inconvenience, recourse was had to other methods of estimation; but which, in fact, amounted only to descriptions more or less vague, and not to measures. Thus, in ancient authors, we frequently read of a day's journey, a day's sail, and so forth; and in many parts of the continent of Europe, even at the present time, it is the custom of the peasantry to reckon itinerary distances by hours.

On looking among the objects of nature for a standard of measure perfectly definite, and, at the same time, invariable, and accessible to all mankind, a very slender acquaintance with geometry and natural philosophy will suffice to show that the subject is beset with innumerable difficulties. In fact, nature presents only two or three elements which, with the aid of profound science and a refined knowledge of the arts, can be made subservient to the purpose; and none at all which are applicable without such aid. The earth is nearly a solid of revolution, and its form and absolute magnitude are presumed to remain the same in all ages: hence the distance between the equator and the pole is an invariable quantity; and any assigned part of that distance, as the 90th, or a degree

of the meridian, is constant, and will furnish a precise and unalterable standard of measures, fit for the purposes of metrology, provided we have the means of comparing it with the rods or scales which must necessarily be used in comparing distances, or the magnitudes of bodies. The force of gravity at the earth's surface is constant at any given place, and very nearly the same at all places under the same parallel of latitude and at the same height above the level of the sea; hence the length of a pendulum which makes a given number of oscillations in a day is also constant at a given place, and, with proper skill and precautions, may be determined in terms of any assumed scale. These two elements, the length of a degree of the meridian, and the length of the seconds' pendulum, are the only ones furnished by nature which have yet been used as the basis of a system of measures. One or two others have been suggested, as the height through which a heavy body falls in a second of time, determined, like the length of the pendulum, by the force of gravity; or the perpendicular height through which a barometer must be carried till the mercurial column sinks a determinate part—for example, a 30th of its own length; but, for reasons which it is unnecessary here to state, these distances are not so susceptible of being accurately determined as the terrestrial degree, or the length of the seconds' pendulum.

English Standard Measures.—The unit of lineal measure in this country is the yard, all other denominations being either multiples or aliquot parts of the yard. But as this is an entirely arbitrary measure, and until the year 1824 was never strictly defined by the legislature, great perplexity has often arisen in attempting to ascertain the exact portion of space which it was meant to represent. For the purpose of preserving some degree of uniformity among the ordinary measures of the kingdom, certain standards were preserved in the exchequer, with which all rods were required to be compared before they were stamped as legal measures. The oldest of these standards in existence dates from the reign of Henry VII.; but it has long been disused; and that which, till the year 1824, was considered as the legal standard, was a brass rod, of the breadth and thickness of about half an inch, placed there in the time of Elizabeth. There was another similar rod of the same date, called an *ell*. The *ell*, however, does not appear ever to have been established as a legal measure; but was conventionally considered as equal to a yard and a quarter. To these rods belonged a brass bar, on one edge of which was a hollow bed or matrix fitted to receive the square rod of a yard, and on another a like bed fitted to receive that of an *ell*; and into these beds were fitted the yard and *ell* measures brought to be examined and stamped with the standard marks. All rods so stamped became standard measures. It is abundantly obvious that measures determined in this coarse manner could have no strict claim to be

MEASURE

considered as *accurate* copies of the original standard; but it would seem that the standard itself was incapable of affording any definite or correct measure. Subsequently in 1742 some Fellows of the Royal Society and members of the Academy of Sciences at Paris constructed a new standard, taken from one found in the Tower; it consisted of a solid brass bar, 1·01 inch square and 39·06 inches long. At about 1½ inch from each end a gold pin or stud was inserted; in which pins, at the distance of 36 inches, are two points intended to designate the length of the yard. In 1760 Mr. Bird constructed another standard similar to that last described, of which, indeed, it was intended to be a copy. This last standard was adopted by parliament in June 1824, an Act having been passed in that year in which the unit of measure was for the first time defined, and in the following terms:—

‘The straight line or distance between the centres of the two points in the gold studs in the brass rod, now in the custody of the clerk of the House of Commons, whereon the words and figures *Standard yard, 1760*, are engraved, shall be, and the same is hereby declared to be, the original and genuine standard of that measure of length or lineal extension called a *yard*; and the same straight line or distance between the centres of the said two points in the said gold studs, in the said brass rod, the brass being at the temperature of 62° of Fahrenheit’s thermometer, shall be and is hereby denominated the *imperial standard yard*, and shall be, and is hereby declared to be, the unit or only standard measure of extension.’ And the Act further declared, that if at any time hereafter the said imperial standard yard shall be lost, or shall be in any manner destroyed, defaced, or otherwise injured, it shall be restored by making, under the directions of the Lords of the Treasury, a new standard yard, bearing the proportion to a pendulum vibrating seconds of mean time, in the latitude of London in a vacuum, and at the level of the sea, as 36 inches to 39·1393 inches.

This scale was destroyed by the fire which consumed the two houses of parliament in 1834. In 1838 a commission was appointed to take steps for its restoration, and the following decisions were carried out in the construction of the new one. A line standard, or a bar on which the measure of length was defined as the distance between two marks, was preferred to an end standard, in which the measure would be the whole length of the bar. The material of the bar to be gun-metal, its form a square rod 38 inches long, on which two fine lines, transverse to the axis of the bar, marked on two small gold plugs, defined the length of the standard measure. The new standards and parliamentary copies have been deposited at the Exchequer, Royal Mint, Royal Society, Royal Observatory, and the Houses of Parliament. (*Phil. Trans.* 1867.)

English System of Lineal Measures.—The unit of measure, as already stated, is the yard.

The yard is divided into three feet, and the foot subdivided into twelve inches. The multiples of the yard are the pole or perch, the furlong, and the mile; five and a half yards being a pole, forty poles a furlong, and eight furlongs a mile. But the pole and furlong are now scarcely ever used, itinerary distances being reckoned in miles and yards. The relations of these different denominations are exhibited in the following table:—

In.	Feet	Yards	Poles	Furlongs
1	0·083	0·028	0·00500	0·00016666
12	1	0·333	0·08000	0·00151515
36	3	1	0·1818	0·004545
108	9	3	0·5454	0·013636
1080	90	30	5·4545	0·136363
65568	5460	1710	340	8

Measures of Superficies.—In square measure the yard is subdivided as in general measure into *feet* and *inches*; 144 square inches being equal to a square foot, and nine square feet to a square yard. For land measure the multiples of the yard are the *pole*, the *rood*, and the *acre*; thirty and a quarter (the square of five and a half) square yards being a pole, forty poles a rood, and four roods an acre. Very large surfaces, as of whole countries, are expressed in square miles. The following are the relations of square measure:—

Sq. Feet	Sq. Yards	Poles	Roods	Acres
1	0·1111	0·00067309	0·000091827	0·000022917
9	1	0·0330579	0·000826448	0·000206612
272·25	30·25	1	0·025	0·00625
10890	1210	40	1	0·25
43560	4840	160	4	1

Measures of Volume.—Solids are measured by cubic yards, feet, and inches; 1,728 cubic inches making a cubic foot, and 27 cubic feet a cubic yard. For all sorts of liquids, corn, and other dry goods, the standard measure is declared by the Act of 1824 to be the *imperial gallon*, the capacity of which is determined immediately by weight, and remotely by the standard of length, in the following manner: According to the Act, the imperial standard gallon contains ten pounds avoirdupois weight of distilled water, weighed in air at the temperature of 62° Fahrenheit’s thermometer, the barometer being at thirty inches. The pound avoirdupois contains 7,000 troy grains; and it is declared that a cubic inch of distilled water (temperature 62°, barometer thirty inches) weighs 252·458 grains. Hence the contents of the imperial standard gallon are 277·274 cubic inches. The parts of the gallon are *quarts* and *pints*; two pints being a quart, and four quarts a gallon. Its multiples are the *peck*, the *bushel*, and the *quarter*: the peck being two gallons, the bushel four pecks, and the quarter eight bushels. The following are the relations:—

Pints	Quarts	Gallons	Pecks	Bushels	Quarters
1	0·5	0·125	0·0625	0·015625	0·001953125
2	1	0·25	0·125	0·03125	0·00390625
8	4	1	0·5	0·125	0·015625
16	8	2	1	0·25	0·03125
64	32	8	4	1	0·125
512	256	64	32	8	1

MEASURE

For an account of the various other measures used in commerce, see the *Commercial Dictionary*; or Colonel Pasley's *Observations on the Measures, Weights, and Money used in this Country* (London 1834), where a full description is given.

French System of Measures.—The French system of measures, introduced during the Revolution, has for its standard the length of a quadrant of the earth's meridian. The unit of measures of length is the *mètre*, which is a ten-millionth part of the quadrant. This length, deduced from the great trigonometrical measurement of the meridian from Dunkirk to Barcelona, is marked by two very fine parallel lines drawn on a bar of platinum, and preserved in the archives of the Academy of Sciences. From a comparison of the standards of this country with a copy of the *mètre* in the possession of the Royal Society, Captain Kater found the length of the *mètre* to be 39·37079 inches of the English standard. (*Phil. Trans.* 1818.) Mr. Baily found the length of the *mètre* to be 39·3696786 inches of the Royal Astronomical Society's scale (*Mem. R.A.S.* vol. ix. p. 133), from which, by reducing to the imperial standard yard by the data given in the same memoir, the true length of the *mètre* is 39·370091 inches of the imperial yard. The comparison is, however, attended with some degree of uncertainty, from the circumstance that a reduction must be made for the expansion of the metals; the standard temperature of the English measures being 62° Fahrenheit, and that of the French measures 32°, or the temperature of melting ice.

In the French system the unit of superficial measure is the *are*, a surface of ten *mètres* each way, or one hundred square *mètres*. The unit of measures of capacity is the *litre*, a vessel containing the cube of a tenth part of the *mètre*, and equivalent to 0·220097 parts of the British imperial gallon. The standard temperature is that of melting ice. All the divisions and multiples of the units are decimal; and the principle of nomenclature adopted was to prefix the Greek numerals to the decimal multiples, and the Roman numerals to the decimal subdivisions.

No system of metrology hitherto invented can be compared with this of the French in a scientific point of view; whilst its convenience for the purposes of commerce is now so generally admitted by those who have made themselves intimately acquainted with its working, that its universal adoption by all civilised nations cannot be much longer delayed. [**METRIC SYSTEM.**]

Of the different measures of length used in European countries, the foot is the most universally prevalent. We subjoin the relation between the foot of different countries and the English foot:—

	English foot
Russian foot . . .	= 1
Paris foot . . .	= 1·065765
Prussian and Danish foot =	1·029722

MEASURES AND WEIGHTS

	English foot
Bavarian foot . . .	= 0·957561
Hanoverian foot . . .	= 0·958333
Saxon foot . . .	= 0·929118
Austrian foot . . .	= 1·037128

Comparative tables of the measures used in different countries are given in various works; one of the most complete and convenient will be found in Hulsse's *Sammlung Mathematischer Tafeln*, Leipzig 1840. For further information on the subject of this article, see Paughton's *Métrologie, ou Traité des Mesures*, Paris 1780; Kelly's *Universal Cambist*, 1821. [**LEAGUE; MILE; WEIGHT.**]

MEASURE. In Music, the same as **BAR** [which see].

Measure of Curvature. [**CURVATURE.**]

Measures. In Geology, this word is sometimes used as synonymous with beds or strata; as *coal measures*.

Measures and Weights, Ancient English. The basis of the ancient English measures of capacity and weight was the ancient Anglo-Saxon pound. The pound contained 5,400 grains, these grains being 22½ to the pennyweight, and the pennyweight being calculated as 32 grains of average quality dry wheat, taken from the middle of the ear. Eight of these pounds were to form the gallon of dry and liquid measure, 8 of these gallons the bushel, 8 of these bushels the quarter. The old English pound, therefore, stood to the troy pound in the relation of 15 to 16. Some few standard gallons and bushels have been preserved, and are generally found to be somewhat less than the exact proportion indicated by this calculation. The troy pound was not known as a legal standard, it would appear, till certain changes were introduced into the currency by Henry VIII.

Again, the sack of wool was roughly calculated as equal in weight to the quarter of corn; 15 Saxon ounces formed the *libra mercatoria*, i.e. the pound of 7,000 grains with which we are familiar under the name of *avoirdupois*. Fourteen such pounds made the stone of wool, and 28 such stones constituted the sack. Such a calculation will be found to make the sack of wool lighter than the quarter of wheat by nearly four pounds.

Another element of weight was the *charrus* of lead. This contained 2,100 *avoirdupois* pounds, and divided by the old hundred, i.e. 108 lbs., will be found to contain nearly 19½ hundred, that is the modern fother or fodder. The *charrus* contained 30 *fothmale*, or *pedes*, each *pes* containing six stones less 2 lbs. The foot or pig will be found to be the tenth of a cubic foot of lead.

Iron was measured by the *piece*, 25 of which formed the hundredweight of 108 lbs. Wax and spices were reckoned by the same hundred. Foreign cloth was sold by the *piece* of 24 ell-long and 2 broad, the exactness of the measure being secured by a rigorous assize. Aylesham linen was, however, only ¾ broad.

Wine was sold by the tun of 252 gallons, i.e. it contained 4½ French or 10 Spanish hogs-

MEASUREMENT OF SHIPS

heads. A familiar division is that of the sextary or six gallons.

A last of wool was 12 sacks; a last of herrings ten thousand, each hundred being 120. A last of hides was 100, that is 10 dakers or dikers, each daker being 10.

The foot, the yard, and the acre were the same as at present. The fullest account of ancient English measures, though apparently with some corruptions in the text, is to be found in Flota, *De Legibus Anglia*, lib. ii. cap. xii. The assize of weights and measures was the duty of the coroner, and the duty of stamping them belonged to the justices in eyre. The coroner was assisted by a jury of twelve men, who might be villains if necessary.

Measurement of Ships. [TONNAGE.]

Meat, Preservation of. [PRESERVATION OF MEAT.]

Meatus Auditorius. [EAR.]

Mecca Balsam. The produce of the *Balsamodendron gileadense*, growing at Gilead, in Judæa. It is also called *Opobalsamum*.

Mechanical Curve. A curve of such a nature that the relation between the absciss and the ordinate cannot be expressed by an algebraic equation. Such curves are now more commonly called *transcendental curves*. [CURVE.]

Mechanical Powers. The six simple machines known as the LEVER, the WHEEL AND AXLE, the INCLINED PLANE, the WEDGE, the SCREW, and the PULLEY [see the respective terms].

Mechanical Solution of a Geometrical Problem. In the constructions of pure geometry only the ruler and compasses are allowed to be used; or, in other words, the constructions are required to be effected by means of straight lines and circles only. The ancient geometers soon discovered that there were many problems (such as the duplication of the cube and the trisection of an angle) which could not be constructed by these means. They hence had recourse to other instruments (*machines*) to effect this purpose; and such solutions were distinguished from the geometrical ones by the term *mechanical*.

Mechanical Work. The exertion of force through space. It is estimated in foot-pounds, the unit being the work performed in raising one pound avoirdupois, against gravity, to a height of one foot. In the modern mechanical theory of heat the utmost mechanical work that can be accomplished by the expenditure of a quantity of heat sufficient to raise one pound of water one degree (Fahrenheit) in temperature, is called the *mechanical equivalent of heat*. According to Joule's experiments it is equal to 772 foot-pounds.

Mechanics (Gr. *μηχανή*, *machine*). In Natural Philosophy, the science which treats of forces and powers, and their action on bodies, either directly or by the intervention of machinery.

The theory of mechanics, which is a branch of mixed mathematics, is founded on an axiom

MECHANICS' INSTITUTES

or principle called the *law of inertia*, or Newton's *first law of motion*; namely, that a body must remain for ever in a state of rest, or in a state of uniform and rectilinear motion, if it be not disturbed by the action of an external cause. Theoretical mechanics is, therefore, divided into two parts: *statics*, which treats of the equilibrium of forces; and *dynamics*, which is the science of accelerating or retarding forces, and of the actions which those forces produce. When the bodies under consideration are in the fluid state, these become respectively *hydrostatics* and *hydrodynamics*, which are comprehended under *hydraulics*, and sometimes the terms *aërostatics* and *aërodynamics* are used to denote the corresponding divisions of pneumatics; but all these divisions are more frequently included under the general term *mechanics*.

Practical mechanics, or a knowledge of the effects of some of the mechanical powers, must have existed to some extent from the earliest ages of the world; but of the machines used by the ancients in their constructions, the oldest extant account is contained in the *Architecture* of Vitruvius. Archimedes, in his treatise *De Equiponderantibus*, first investigated theoretically the principles of equilibrium; and the same philosopher is celebrated for the mechanical contrivances by which, in the siege of Syracuse, he so long frustrated the efforts of the Roman army under Marcellus. During the eighteen centuries which succeeded the age of Archimedes, the theory of mechanics remained in the same state. Galileo laid the foundations of modern dynamics by his discovery of the law of accelerating forces, and by reducing the propositions of that science to mathematical formulæ. Sir Isaac Newton, by his invention of fluxions, enabled mathematicians to complete what Galileo began.

Although we possess many works of the highest order on isolated branches of mechanics, Poisson's *Traité de Mécanique* (Paris 1833) still remains the most complete treatise on the subject. Of first-class elementary treatises in English a great number might be cited; of the more recent ones, that by Price in the 3rd and 4th volumes of his *Treatise on the Infinitesimal Calculus* (Oxford 1856) deserves high commendation.

Mechanics' Institutes. Mechanics' institutes may be safely said to owe their origin to Dr. Birkbeck, who, in 1800, delivered a course of lectures on natural philosophy and its application to the arts before an audience composed entirely of the mechanics of Glasgow, though it was not until after the lapse of twenty years that his idea was followed up. Institutions of this sort are at present established in almost every town in England whose population amounts to 10,000, and in some of much smaller number. They are supported partly by contributions, and partly by the subscriptions of the members. Short courses of lectures, illustrated with experiments, are given on popular and interesting subjects, and reading rooms are

MECHANISTS

attached to the greater number of these institutions, which, speaking generally, are well attended. (*Stat. of Brit. Empire*, vol. ii. p. 359.)

Mechanists. Those philosophers who refer all the changes in the universe to the effect of merely *mechanical* forces, such as *impact*, *weight*, and the like. They are opposed to the dynamical philosophers, or those who assume a living and spontaneous power in nature, antecedent to and different from the phenomena present to the senses. [MATERIALISM.]

Mechoacan. One of the names of *Batatas Jalapa*, the tuberous roots of which possess purgative properties, analogous to those of the true jalap.

Meconic Acid (Gr. *μήκων*, the poppy). The peculiar acid with which morphia and perhaps some of the other organic bases are combined in opium. When pure, it forms small white crystals. The salts of this acid are termed *meconates*; those of lime, baryta, lead, and silver are white, and soluble in nitric acid. This acid is tribasic, and the somewhat anomalous formula $3\text{HO}, \text{C}_{14}\text{HO}_{11}$, has been assigned to it. One of the principal characters of this acid and of its salts is that of forming a compound with the peroxide of iron of an intensely red colour, very similar to that of the sulphocyanate of iron, but differing in the fact that a solution of corrosive sublimate does not destroy the red colour; hence a persalt of iron is an excellent test of its presence, and by it opium may sometimes be recognised, when the quantity is so small as to render the morphia very difficult of detection. This red colour is destroyed by heat, by sulphurous acid, and by protochloride of tin. Meconic acid in solution gives a yellowish-white precipitate with acetate of lead, and this precipitate is not dissolved by acetic acid. It is medicinally inert.

Meconin (Gr. *μήκων*). *Opianyl*. A white neutral fusible substance, procured from opium. About two grains of it are said to be contained in a pound of opium.

Meconium (Gr. *μηκόνιον*, the juice of *μήκων*, the poppy). Opium. The term is also applied to the excrement found in the lower part of the fœtal intestines.

Medal (Ital. *medaglia*, Fr. *medaille*). A piece of metal, in the shape of a coin, bearing figures or devices, struck and distributed in memory of some person or event. Ancient coins, although intended for the purpose of circulation, are also commonly termed medals. [NUMISMATICS.]

Medallion (Fr. *medaillon*). In Architecture, this word is applied to carvings on the plain spaces of the walls, surrounded by a raised border.

MEDALLION. In Numismatics, this name is appropriated to coins struck in Rome and in the provinces under the empire, which, in gold or silver, exceed in size the largest coins of which the name and value are known in those respective metals; viz. the aureus in gold, and the denarius in silver. It has been doubted

MEDEA

whether they were intended for the purpose of circulation, or merely struck, like modern medals, to commemorate persons or events. [NUMISMATICS.]

Medea or Medeia (Gr.). In Greek Mythology, a daughter of *Æetes*, king of Colchis, in whose palace was preserved the golden fleece of the ram which had borne Phrixus and his sister Hellé from the house of Athamas. The recovery of this golden fleece was the task imposed by Pelias, king of Iolcos, upon Jason, who sailed from Thebes with a large number of Hellenic chieftains in the ship *Argo*, and after having passed through the *Symplegades*, arrived at length in Colchis. Here *Æetes* promised to give him the fleece, on condition that he should first plough the land with fire-breathing bulls, and sow it with dragon's teeth. These conditions Medea, the wise maiden, whose love Jason had obtained, enabled him to perform. She anointed his body with an ointment which protected him against the fiery breath of the bulls, and told him to cast a stone among the armed men who sprang from the dragon's teeth, so that they should fight with and slay one another. Then leading Jason to the secret place where the fleece was kept, she lulled to sleep the dragon that guarded it, and then left Colchis with Jason, who had now performed the bidding of Pelias.

But Medea had sworn to avenge the wrong done to Jason; and as she abode in the house of Pelias at Iolcos, she persuaded his daughters to cut up his body and boil his limbs in a cauldron, in the belief that he would thus be restored to youth. Medea purposely omitted to pronounce the spell at the right time, and the limbs of Pelias were consumed by the fire. She then took Jason in her dragon chariot to Argos, where he fell in love with Glaukè, the daughter of the king, Creon. Disguising her wrath, she gave to Glaukè, as bridal presents, a wreath with a robe which Helios (the sun) gave her before she left the house of her father *Æetes*. But the magic gifts ate into her flesh, and Creon, who tried to save her, died with his daughter Glaukè, while Medea fled from the land in her dragon chariot. In the sequel of the tale, she slays her children by Jason—a crime closely resembling the slaughter of Pelops by Tantalus.

The connection of this myth with other solar legends is obvious. In the Homeric hymn to HÆRMES [which see], the sun god Phœbus is represented as possessed of a hidden wisdom which Hermes vainly seeks to attain. This wisdom is inherited by Asklepios (*Æsculapius*), the son of Phœbus, and by Medea, the Colchian maiden. The very gift which Helios bestows on her reappears in the story of Deianeira, whose robe scorches the body of Hercules. The robe is, in fact, the same as the golden fleece, and its destructive power is exhibited in the deadly arrows of Philoctetes, the sword of Theseus and of Perseus, the spear of Artemis, Meleagros, and Achilles. In the legend of

MEDIÆ

Medea, Jason plays the part of Paris in that of *Œnônê*, and *Glaukê* answers to the Argive Helen. The slaughter of Medea's children is one of the many forms under which is displayed the destructive power of the sun on the fruits which he has produced. This idea is prominent in the myths of *Phaëthon*, *Lykaon*, and *Tantalus*, while the notion of the sun's secret wisdom presents one of the sources from which seem to have sprung the theories of sorcery and witchcraft.

Mediæ (Lat.). The three letters *b*, *g*, and *d* (beta, gamma, delta) are so called in the Greek alphabet, as holding respectively a middle place between their several *tenues*, *p*, *k*, *t* (pi, kappa, tau), and aspirates, *ph*, *ch*, *th* (phi, chi, theta).

Mediant. In Music, the third note of the scale, which is a major or minor third higher than the key note, according as the mode is major or minor.

Mediastinum (Lat. from *medius*). The space left in the median line of the chest by the non-approximation of the two lungs. It extends from the sternum in front to the spine behind, and contains all the thoracic viscera excepting the lungs.

Mediatisation. The annexation of the smaller German sovereignties to larger contiguous states, which took place, on a large scale, after the dissolution of the German empire in 1806. The same thing had been done on various occasions during the continuance of the empire; and the dominions so annexed were said to be mediatised, i.e. made mediately instead of immediately dependent on the empire. The term was retained when the abolition of the German union had rendered it in strictness inappropriate. A few more were mediatised after the peace of 1815. See *Conv. Lex.*; and Hawkins's *Germany*, 1838, which contains a chapter on this subject.

Medicago (Gr. *Μηδική*, a term applied by Dioscorides to a Median grass). A genus which affords some agricultural fodder plants. *M. sativa* is the Lucern so much cultivated as green food for horses and cattle; and *M. lupulina* is the Nonsuch introduced into pastures along with grasses and clovers.

Mediterranean Sea. This large and beautiful sea, separating Europe from Africa, opening into the Atlantic only by the narrow straits of Gibraltar, and communicating with the Black Sea by the straits of the Hellespont and Bosphorus, between which lies the narrow sea of Marmora, contains nearly a million square miles of water, of considerable depth, and much more salt than the great ocean. Its waters are several degrees warmer than those of the Atlantic, and the evaporation from it, from various causes, is excessive. The depth of some parts is as much as a thousand fathoms. The shores of the Mediterranean are exceedingly indented; and many islands, some of large size, and most of them of singular historical interest, are contained in it. The islands of Sardinia and Corsica, the Balearic Islands, Malta, Sicily, the

MEDLAR

Ionian Islands, the islands of the Greek Archipelago, and others, are all familiar examples.

The Mediterranean is crossed by a submarine bank, almost connecting Sicily with Africa, and nearly dividing the sea into two parts. The eastern portion is in some respects distinct from the western. It receives many important streams, of which the Nile is the principal; but the supply of fresh water is by no means equal to the evaporation from the surface, and thus a constant current sets inwards through the straits of Gibraltar to supply the deficiency.

Very large parts of the Mediterranean are more or less directly influenced by volcanic action and earthquakes, and more than once its bed has been broken, and perhaps upheaved, and islands have suddenly appeared where before there had been deep water. The great volcanoes of Etna and Vesuvius, the smaller but constantly erupting volcanoes of the Lipari islands, and the volcanic rocks of the eastern shores, all prove that subterranean fires largely act under its bed; and the occasional evidence of slow upheaval or depression on the coasts of Italy, prove that the action, so far as great eruptions are concerned, although intermittent, is constantly going on.

The shores of the Mediterranean include some of the most interesting districts of the civilised world. They branch into several seas, of which the Adriatic and the Ægean are the most familiar. They possess many harbours and ports, and the shores are picturesque in the highest degree.

Several currents of small magnitude have been observed in this inland sea. They are for the most part sluggish and very variable, and seem to depend on prevalent winds. There is a slight tide in most parts of the Mediterranean; but it is greatly masked by the effect of winds.

Medium. In Physics, the substance or matter in which bodies exist, or through which they move in passing from one point to another. The resistance which different mediums oppose to bodies in motion is proportional to the respective densities of the mediums. Newton supposed the existence of a universal medium, or ether, infinitely more rare or subtle than air, and diffused through the whole creation. The modern discoveries of the propagation of light by undulation, and of the acceleration of some of the small comets, caused apparently by the resistance which it offers (hence the term *resisting medium*), give great probability to this supposition.

Medjidite. A sulphate of uranium and lime, found near Adrianople, in Turkey, and named after the late sultan Abdul Medjid.

Medlar. The fruit of the *Mespilus germanica*, a plant found wild in several parts of Central Europe. It is remarkable for the austerly of its fruit when first gathered, and for its total loss of that quality after a few weeks, when it becomes soft, brown, and sweet—a condition called *blotted*, from the French *blot*, over-ripe. Of the garden varieties the Dutch medlar is the finest as to size, and the Notting-

ham the most delicate in flavour. In the eyes of a botanist the medlar is only a hawthorn berry of large size.

Medulla (Lat. *marrow*). In Botany, the pith or central column of an Exogenous plant. It has sometimes been called *medulin*.

Medulla Oblongata. In Anatomy, the name given to the mass of grey and white neurine contained in the occipital segment of the cranium, and forming the medium of connection between the spinal marrow (myelon) and the brain (encephalon): it is sometimes described as the cephalic prolongation of the myelon; but it has distinct and higher functions, and constitutes the chief part of the encephalic division of the brain. [BRAIN.]

Medulla Spinalis (Lat. *the spinal pith*). In Anatomy, the part of the nervous axis which is contained in the vertebræ of the trunk. [MYELON.]

Medullary. Belonging, or alike in nature, to marrow, as *medulla spinalis*, the *myelon* or spinal marrow; *medulla oblongata*, that part of the myelon which lies within the basioccipital bone; medullary substance, the white substance of the brain, and the inner, as opposed to the cortical substance of the kidney.

Medullary Rays. The vertical plates of cellular tissue which radiate from the centre of the stem of Exogenous plants, through the wood to the bark. They cause that appearance in timber which carpenters call silver grain, or flower of the wood.

Medullary Sheath. A thin layer of vessels which surround the pith of Exogenous plants, and thence extend into the leaves and parts of fructification.

Medullary Substance. The interior white portion of the brain. The *medulla oblongata* is a part of the brain, lying upon the basilar process of the occipital bone, and formed by the junction of the crura of the brain and cerebellum. It terminates in the spinal marrow.

Medusa (Gr. *μέδουσα*, a ruler). In Mythology, the mortal GORGON [which see]; according to Hesiod, the daughter of Keto and the sea-god Phorkys, whose face turned all who looked upon her into stone. She was slain by Perseus, who placed her head on the ægis of Athênê, where it retained its petrifying power.

MEDUSA. In Zoology, a name given by Linnaeus to a genus of marine animals, now forming an extensive tribe (*Medusaria*) in the class *Acalepha* of the Cuvierian system. The body is in the form of a gelatinous disc, more or less convex above, called the *umbel*, from the centre of which, and from the margin, there depend in most of the species processes or filaments more or less numerous, and more or less elongated. The *Medusæ* are commonly known by the name of *sea-blubber*, *jelly-fish*, &c. They have a stomach or digestive cavity excavated in the centre of the disc, and opening externally either by a central and inferior crucial mouth, or continued into branched appendages, and receiving the nutriment by

innumerable minute pores, analogous to the *stomata* of plants, or those root-like appendages. The digested fluid is conveyed by vessels from the stomach to an exquisite network or plexus situated on the under surface of the border of the disc, where it receives the influence of the atmosphere, and is fitted for assimilation. Some species, as the *Medusa aurita*, have also intestinal canals leading from the stomach to separate anal outlets. Traces of a nervous system and rudimental organs of vision have been discerned in some of the *Medusæ*. They swim by muscular contraction of the margins of the disc. They are of distinct sexes, which congregate together chiefly in the autumnal months. The male and female organs much resemble each other, and are situated, in both sexes, in corresponding cavities, generally four in number, on the under surface of the disc. The ova are received when impregnated in marsupial sacs appended to the arms (in *Medusa aurita*), whence they escape in the form of ciliated infusoria, afterwards assume the structure of eight-armed polypes, pass the winter in this state, and undergo their final transformation in spring. Notwithstanding the complication of the organic machinery, functions, and generative economy of the *Medusæ*, their solids form so small a proportion of their frame that, of a *Medusa* of ten pounds weight, what remains upon the filter through which its fluid parts (chiefly sea-water) have escaped does not exceed two drachms. A great number of the *Medusæ* are phosphorescent, shining in the night like globes of fire; but the nature and the agents of this wonderful property remain to be discovered. Most of the *Medusæ* at certain seasons sting and inflame the hand that touches them; but the cause of this property is equally unknown.

Meerschauum (Ger. *foam of the sea*). A hydrous silicate of magnesia. It is found in various parts of Europe, but chiefly in Asia Minor, in stratified, earthy, or alluvial deposits, at the plains of Eski-shehr, and in Natolia at Kiltchik near Konieh. It is dull and opaque, white or yellowish in colour, adheres to the tongue, yields to the nail, and has a specific gravity of only 1.3 to 1.6. In the Turkish dominions it is used as a substitute for fuller's earth, and for washing linen. The principal use of Meerschauum is in the manufacture of tobacco pipes, which are prepared for sale in Germany by being soaked in melted tallow or wax, and afterwards polished. Imitation meerschauum pipes are sold in large quantities, and care is necessary to guard against deception. The best criterion is the peculiar brown colour which the genuine Meerschauum pipe assumes after having been smoked some time.

Megabromite. A variety of chlorobromide of silver found in limestone at Cupiapo in Chili.

Megalesian Games. One of the most magnificent of the Roman exhibitions of the circus; in honour of Cybele, as *ἡ μεγάλη θεός*, the great goddess, the mother of the gods.

MEGALICHTHYS

Megalichthys (Gr. μέγας, *great*, and ἰχθίς, *a fish*). An extinct genus of fishes, including species of great size; one of which, the *Megalichthys Hibberti*, has left its teeth and other parts in the cannel coal of Fifeshire, and the Edinburgh coal-field.

Megalonyx (Gr. μέγας, and οὖνξ, *a claw*). A large fossil mammalian, the remains of which were found in a cavern in the limestone of Virginia in America.

Megalopterans (Gr. μέγας, and πτερόν, *a feather*). A name given by Latreille to a family of Planipennate Neuropterous insects, comprehending those which have large wings horizontally folded.

Megalosaurus (Gr. μέγας, and σαῦρος, *a lizard*). The generic name applied by Dr. Buckland to an extinct genus of gigantic Saurians, discovered by him in the oolitic slate of Stonesfield, near Oxford. The species on which the genus is founded included individuals measuring from forty to fifty feet in length; they partook of the structure of the crocodile and monitor. The entire skeleton has not as yet been found. The femur and tibia measure nearly three feet each; and a metatarsal bone has been found of the length of thirteen inches. The bones of the extremities have large medullary cavities. The generic character is principally founded on the teeth, which Dr. Buckland thus describes: 'In the structure of these teeth we find a combination of mechanical contrivances analogous to those which are adopted in the construction of the knife, the sabre, and the saw. When first protruded above the gum, the apex of each tooth presented a double cutting edge of serrated enamel. In this stage its position and line of action were nearly vertical, and its form like that of the two-edged point of a sabre, cutting equally on each side. As the tooth advanced in growth, it became curved backwards, in form of a pruning knife, and the edge of serrated enamel was continued downwards to the base of the inner and cutting side of the tooth; whilst on the outer side a similar edge descended but to a short distance from the point, and the convex portion of the tooth became blunt and thick, as the back of a knife is made thick for the purpose of producing strength. In a tooth thus formed for cutting along its concave edge, each movement of the jaw combined the power of the knife and saw; whilst the apex, in making the first incision, acted like the two-edged sabre. The backward curvature of the full-grown teeth enabled them to retain, like barbs, the prey which they had penetrated.' (*Brady's water Treatise* i. p. 238.) These formidable teeth, which sufficiently bespeak the carnivorous and predatory nature of the extinct monster, were arranged in a pretty close series, in sockets, along the alveolar border of the jaws.

Meganycterans (Gr. μέγας, and νυκτερίς, *a night bird or bat*). The first division or tribe of the order *Chiroptera*, including the largest species of bats, or *flying foxes*; which, however, are exclusively vegetable feeders, living

MEIONITE

mostly on soft fruits, and having the molar teeth adapted to that kind of food by their broad simple crowns. The tribe is also distinguished from the animal-feeding bats, whether bloodsuckers or insect-catchers, by having the two innermost fingers armed with hook-shaped claws, and by the simple structure of the nose and ears. The alimentary canal, and especially the stomach of the great frugivorous bats, are likewise more complicated than in the other tribes. The meganycterans are distributed over the warmer parts of Asia, Africa, and the Polynesian Isles, but do not exist in America. They comprise the genera *Hypodermis*, *Pteropus*, and *Harpigia*.

Megarian School of Greek Philosophy. This school, founded at Megara by the disciples of Socrates, who retired thither after his death, was distinguished by its logical subtlety. Its most celebrated names were those of Euclides, Eubulides, and Stilpo.

Megastomes (Gr. μέγας, and στόμα, *mouth*). The name of a family of Univalve shells, comprehending those which are not symmetrical, and which have a very large aperture or mouth.

Megatherium (Gr. μέγας, and θηρίον, *a beast*). The name given by Cuvier to a genus of extinct Edentate quadrupeds, including and represented by one of the most gigantic of terrestrial mammalia. The haunches of the *Megatherium Cuvieri* were more than five feet wide, and its body twelve feet long and eight feet high; its feet were a yard in length, and terminated by formidable compressed claws of immense size; its tail was of great length, and probably much larger than that of any other extinct or living terrestrial mammal. The head of the megatherium was relatively small: the cranium presents many of the peculiarities of that of the sloth. The upper jaw was armed with five teeth on each side, the lower jaw with four on each side: all the eighteen teeth belong to the molar series. They were perpetually growing, like the incisors of the Rodents; but had their grinding surface traversed by two transverse ridges, and their texture composed, as in the teeth of the sloth, of a central body of coarse ivory, a thick outer coating of cæmentum, and a thin intermediate layer of fine and dense ivory, which forms the prominent terminating ridges of the crown.

Nothing certain is known of the nature of the integuments of this singular and enormous animal; but the fossil bony armour which was once conjectured to have appertained to the megatherium unquestionably belongs to another species of gigantic Edentates, more nearly allied to the armadillo. [GLYPTODON.]

Megrim (Fr. migraine, from Gr. ἡμικρανία). A violent intermitting pain affecting one side of the head.

Melionite (Gr. μέλιον, *less*). A silicate of alumina and lime, found in grains or small crystals of a whitish or greyish white colour at Monte Somma near Vesuvius. The name implies that the terminating pyramids of the

MELACONITE

crystals are lower than in Idocrase, and consequently that the axis of the primary form is shorter.

Melacconite (Gr. μέλας, *black*, and κόνις, *powder*). An earthy black oxide of copper found in Cornwall and elsewhere.

Melasma (Gr. μέλασμα, fem. of μέλας, *black*). A disease characterised by the passage of dark coloured blood by stool. The pitch-black appearance of the evacuations is so striking, that, when they are once seen, the nature of the affection denoted can scarcely be mistaken. The cause exists apparently in a congested state of the liver and stomach, and the treatment consists in the free use of mercurial purges. The ancients considered that the dark-coloured stools were composed of black bile; but the correct inference from all that we know of the pathology of the disease, is, that the blood passed by stool comes from the congested stomach, having acquired its black colour from contact with the gastric juice. Hippocrates speaks of a μέλασμα νόσος characterised by the vomiting of black blood, but this more properly comes under the title of *hematemesis* in modern nosology.

Melaleuca (Gr. μέλας, *black*, and λευκός, *white*). A genus of *Myrtaceæ* consisting of trees and shrubs, abounding in volatile aromatic oil. *M. minor* yields by distillation of its leaves, after fermentation, the green aromatic oil called Cajaputi or Cajeput oil, a valuable antispasmodic and stimulant. The species are natives of Australia and the islands of the Indian Ocean.

A substance formed during the distillation of a mixture of sal-ammoniac and sulphocyanide of potassium.

Melamine. A colourless crystalline salifiable base derived from melam, by boiling with strong solution of potash.

Melampodium (Gr. μελαμπόδιον). The name of a modern genus of weedy *Compositæ*. *Melampodium* was one of the Greek names given to the Black Hellebore [*HELLEBORUS*], with which the modern plant has no relation.

Melampyrine. A crystallisable substance, soluble in water and nearly insipid, contained in the *Melampyrum nemorosum*.

Melanasphalt. A name given to the Albert Coal of Nova Scotia in consequence of its resemblance to Asphalt.

Melancholy (Gr. μελαγχολία, *black bile*). A disease of the mind, chiefly characterised by ungrounded apprehension of evil. Melancholy is correctly designated a form of insanity when it continues for an inordinate period after any given cause of grief has been removed. It is undoubtedly so when it arises without the operation of any mental cause. We find it connected with dyspepsia, with constipation, and other signs of physical disease. Systematic writers speak of various forms of melancholic insanity, such as the religious, the nostalgic, &c.

Melania. A genus of fluviatile Pectinibranchiate Gastropoda, having a moderately thick shell, with an aperture longer than it is

MELASOMES

wide, enlarging opposite the spire, and the columella without folds or umbilicus: the length of the spire is various. They have long tentacula, with the eyes on their external side, and at about the third of their length from the base.

Melanic Acid. An amorphous black substance derived from hydride of salicyl.

Melanin. The black pigment of the eye. When separated from the surrounding membrane, it is a heavy black powder insoluble in water, alcohol, and ether.

Melanite (Gr. μέλας). A variety of Iron-lime Garnet, occurring in black dodecahedrons in the older lavas of Vesuvius. Those found at Frascati near Rome are locally called *Black Garnets of Frascati*. [GARNET.]

Melanochoroit (Gr. μέλας, *black*; χροά, *colour*). Chromate of lead, found massive and in tabular rhombic prisms, of a colour between cochineal and hyacinth red, at Beresow, in Siberia. The name has reference to the change of colour which the mineral undergoes before the blow-pipe.

Melanogal (Gr. μέλας, *black*; γαλ, *flow*). A synonym of *Metagallic acid*.

Melanorrhosa (Gr. μέλας, *black*, and ῥέω, *I flow*). A genus of *Anacardiaceæ* consisting of large trees natives of India. *M. usitatissima*, common in Indian forests, produces a dark-coloured wood of excessive hardness, so heavy that anchors for native boats are made of it; and also a valuable black varnish, obtained by tapping the trees.

Melanosis (Gr.). A malignant disease, characterised by deposition of a black matter in various parts of the body.

Melanotannic Acid. The black substance formed by the action of excess of potassa upon tannic or gallic acid.

Melanterite. A mineralogical synonym for Native Sulphate of Iron [COPPERAS], derived from the word *Melanteria*, made use of by Pliny to denote the same substance.

Melanthaceæ (Melanthium, one of the genera). An order of Endogenous plants belonging to the Liliæ alliance, with a regular six-parted inferior perianth, and six stamens with the anthers looking outwards. The number of species included in it is inconsiderable; but among them are the *Viviparum*, or White Hellebore, and *Colchicum*, or Meadow Saffron, the poisonous qualities of which indicate the general properties of the order.

Melanuronic Acid. A product of the action of heat on urea.

Melas (Gr. *black*). A disease endemic in Arabia: it consists in the formation of dark brown or black spots upon the skin.

Melasma (Gr.). A disease of aged persons, in which a black spot appears upon the skin, which forms a foul ulcer. A form of melasma is now described by nosologists in connection with disease of the supra-renal capsules, constituting the pathological condition known as *Addison's disease*.

Melasomes (Gr. μέλας, and σῶμα, *body*). A tribe of Heteromeric Coleopterous insects,

MELASSES

comprising those which are of a uniform black or grey colour.

Melasses. [MOLASSES.]

Melassic Acid. An acid produced together with glaucic acid by the action of potash on grape-sugar.

Melastomaceæ (Melastoma, one of the genera). A natural order of Exogenous plants belonging to the Myrtal alliance, with polypetalous flowers and strongly ribbed leaves, inhabiting tropical countries in great numbers, but unknown in Europe in a wild state, and only occurring very sparingly in the temperate parts of America. In the equatorial regions of this continent they are extremely numerous; and some of the species bear berries, the juice of which stains the mouth black; whence their name. Their most characteristic mark is to have the anthers bent downwards and prolonged into a horn, which is held fast in sockets of the ovary before the flower expands. Many of the species are ornamental.

Melchisedecians. In Ecclesiastical History, several sects of early heretics have been so termed, from the opinions entertained by them respecting the character and office of Melchisedec, arising from the language of St. Paul in the Epistle to the Hebrews. The Theodotians, in the third century, are said to have regarded him as superior to Christ. A sect of visionaries in Phrygia, who appear to have been a branch of the Manicheans, are reported to have made Melchisedec an object of adoration. Many divines of later times have entertained the belief that the Son of God appeared to Abraham under the form of Melchisedec. (Cuneus, *De Rep. Hebræorum*.)

Melchites (Syr. malek, king). In Ecclesiastical History, the Eutyrians, when condemned by the council of Chalcedon, gave this name (royalists, imperialists) to the orthodox, who endeavoured to put the order of the emperor Marcian into execution against them. Among Oriental Christians it now designates in a general manner all those who are neither Jacobites nor Nestorians, including the Maronites, Catholic Greeks, and non-Catholic Greeks, of the three Eastern patriarchates.

Meleager or Meleagros (Gr.). In the Homeric Mythology, a chieftain of the Ætolian Calydon, son of Ceneus and Althea, and husband of Cleopatra. A part of the myth connected with the name of Meleagros is repeated by Phoenix to Achilles in the tenth book of the *Iliad*, but this part relates only the war between the Ætolians and the Curiætes, in which Meleagros, angry on account of a curse laid on him by his mother for the slaughter of her brothers, refuses to aid his countrymen, until prevailed upon to do so by his wife Cleopatra. The character of Meleagros as here depicted exhibits the same readiness to take offence, the same sullen moodiness, and alternate energy and inaction which characterise both Achilles and Paris. A passing reference to his death is the only notice taken in the *Iliad* of his later history; but in the other versions the

MELES

tale ran, that while he was a child, the *Mæris* appeared to his mother, and said that he should live only while a brand which lay burning on the hearth should be unconsumed; that Althea immediately extinguished the flame and put the wood carefully away, but when afterwards irritated by the death of her brothers, she threw the wood into the fire, that Meleagros died as its last spark flickered out, and that his death was followed immediately by that of his mother and his wife. Like Achilles and Paris, like Baldr and Sigurd in northern mythology, Meleagros dies young; like them he is invincible in the field; like Theseus, Perseus, and Bellerophon, he is the destroyer of noxious beasts; in the hunt of the wild boar of Calydon, Atalanta exhibits the swiftness and strength of Daphnê, Arethusa, and Kyrênê, while the chase itself is paralleled by the exploits of Heracles and other heroes against the beasts of the field. With him die his mother and his wife, as the death of Heracles and Paris is followed by that of Deianeira and Eriônê; and as Achilles falls at the close of day, so Meleagros dies when the torch of day is burnt out. Like those heroes, again, he can only be slain in one way, or in one vulnerable spot, and his sisters weep for his death, until they are changed into guineahens (*meleagrides*), as the sisters of Phaethon shed amber tears over his dead body and are changed into poplars.

Meleagris (Gr.). A term employed by Linnaeus to designate the genus of which the turkey is the type. The head and upper part of the neck is invested with a plumbeous and carunculated skin: there is a cutaneous appendage of a similar construction under the throat, and another of a conical form on the forehead, which in the male, when under excitement, can be distended and elongated so as to hang over the point of the beak. From the lower part of the neck of the adult male hangs a tuft or tassel of stiff hairs. The coverts of the tail are shorter and stiffer than in the peacock, but can be erected and displayed in the same way. The tarsi of the male are armed with weak spurs. The common turkey (*Meleagris Gallopavo*, Linn.) was introduced into Europe in the sixteenth century. Its size, and the excellence of its flesh, led to its being cultivated with peculiar care: it is now common, and widely dispersed. Its wild original of the American woods is of a greenish colour, with a copper gloss. A second and much more beautiful species (*Meleagris ocellata*, Cuvier) has been discovered in Honduras: its domestication is greatly to be desired. The Guinea-fowl is the *Meleagris Numida*. [NUMIDA.]

Meles (Lat.). A genus separated by Storr from the Linnean *Ursus*, and characterised by Mr. Bell as follows: Second incisor in the lower jaw placed behind the others; premolars 4-4 molars 1-1 arranged in an uninterrupted series; feet plantigrade; a glandular pouch underneath the tail, having a transverse orifice.

MELETIANS

Since the extirpation of the common bear, the badger, *Ursus Meles* of Linnaeus, which is a typical species of the present genus, is the sole representative of the Ursine family in our indigenous zoology. The habits of this quadruped are nocturnal, inoffensive, and slothful; its food consists of roots, earth nuts, fruits, the eggs of birds, insects, reptiles, and the smaller quadrupeds; its noxious qualities are consequently few and of slight moment, and by no means justify the exterminating war unintermittingly waged against it. The muscular strength of the badger is great, its bite proverbially powerful; and a dog must be trained and encouraged to enter willingly into a combat with this species. The long claws of the fore feet enable the badger to dig with effect; and he habitually dwells in burrows, which he digs by choice in declivities covered by thick coppice, or concealed in the recesses of woods. The female prepares a nest of moss and grass, and brings forth her litter of three or four blind young in the summer season.

Meletians. In Ecclesiastical History, the partisans of Meletius, bishop of Lycopolis in Egypt, deposed in a synod at Alexandria about 306, on the charge of having sacrificed to idols during the persecution by Diocletian. He was supported by numerous adherents; and thus a schism began, which was partially concluded by the submission of Arsenius, chief of the party, to Athanasius in 333, but does not seem to have been wholly extinct for 150 years.

Meliaceæ (Melia, one of the genera). A natural order of hypogynous Exogens of the Rutal alliance, known by their dotted leaves, deeply monadelphous stamens, consolidated berried or capsular fruit, and few wingless seeds. The order is moderately extensive, and includes the *Melias*, *Trichilias*, *Guarcas*, *Carapas*, and other interesting and useful genera of the tropical parts of Asia and America.

Meliceris (Gr. μέλι, *honey*, and κηρός, *wax*). An encysted tumour, the contents of which resemble honey.

Mellite (Gr. μέλι, *honey*, and λίθος, *stone*). A silicate of alumina, peroxide of iron, lime, magnesia, soda, and potash, found in small square prisms of a yellowish colour, and generally coated with oxide of iron, in the fissures and cavities of lava, at Capo di Bova, near Rome.

Mellilotus (Gr. μέλι, *honey*, and λóτος, *lotus*). A genus of *Leguminosæ*, of which two or three species are cultivated in several parts of Europe as fodder plants, in the same way as lucern. The common Melilot, *M. officinalis*, is an annual or biennial, three or four feet high, with erect racemes of yellow honey-scented flowers. It cut continually and not allowed to flower, it will last several years. *M. alba* is the Bokhara Clover, the aromatic flavour of which recommends it for admixture with hay which has lost some of its savour. This is an excellent bee plant. The Melilots have a peculiar odour owing to the presence of *coumarin*; this is most apparent in the *M. caeruleus*, employed in Switzerland for flavouring chappziger cheese.

MELOË

Meliphagans (Gr. μέλι, *honey*, and φάγειν, *to eat*). A family of Tenuirostres, comprising the birds which feed on the nectar of flowers.

Mellitææ or **Melinoææ**. In Zoology, a genus of beautiful corals, and also a genus of butterflies.

Mellite. A native hydrous *mellate* of alumina. It occurs in yellowish octahedrons, and was first observed in the Brown Coal of Arten, in Thuringia.

Mellitic Acid. The peculiar organic acid contained in the mellite or honey stone of Thuringia.

Mellocææ. The *Mellocæa tuberosa*, sometimes called *Ullucus tuberosus*, is an herbaceous perennial, much cultivated throughout the elevated regions of Bolivia, Peru, and New Granada, on account of its esculent tubers, which resemble small yellow potatoes. The plant forms a genus of *Basellacææ*, and has weak fleshy ternary stems, with fleshy heart-shaped roundish leaves and short spikes of inconspicuous yellow flowers. The tubers are called *Oca quina* in Bolivia, to distinguish them from other Ocas belonging to the *Oxalis* family.

Mellon. A lemon-yellow substance composed of six equivalents of carbon and four of nitrogen, obtained by heating dry sulphocyanogen. It is a compound radical, and combines with metals to form *Mellonides*.

Melocactus (Melon-cactus). A genus of round-stemmed or globular-ribbed succulent plants, covered with spines on the ridge of the ribs, and producing the flowers among wool, on a hairy head or cap, which is protruded from the top of the stem. They were included by Linnaeus in his genus *Cactus*; and they are, in fact, scarcely distinguishable from those dismemberments of the genus to which the modern names of *Cereus* and *Echinocactus* are applied. For the sake of their grotesque form, they are often cultivated by persons curious in collecting singular vegetables.

Melodrama (Gr. μέλος, *song*, and δράμα, *drama*). A short drama in which music is introduced; but differing from the opera, as the greater part of the words are recited, and not sung. In Germany, the melodrama is a short dramatic piece in lyrical verse; but among ourselves, and in France, its character is chiefly that of being a vehicle for gorgeous decoration and scenery, with an insignificant plot.

Melody (Gr. μελωδία). In Music, the arrangement, in succession, of different sounds for a single voice or instrument, as distinguished from harmony, which is the result of the union of two or more concurring musical sounds.

Meloë (Gr. μέλη, *a probe*). A genus of Coleopterous insects, of the section *Heteromera*, tribe Trachelides, and family Cantharidæ, in the system of Latreille. In this genus the antennæ are composed of short and rounded joints, the intermediate of which are the largest, and sometimes so disposed that these organs present in this point, in several males, an emargination or crescent. The wings are wanting; and the elytra, oval or triangular, with a portion

of the inner margin, crossing each other, only partially cover the abdomen, particularly in the females, in which this segment of the body is extremely voluminous. The meloë crawl along the ground, or upon low plants, on the leaves of which they feed. A yellowish or reddish oleaginous liquid exudes from the articulations of their legs. In some districts of Spain these insects are used in the place of the true blister-flies (*Cantharides*); they are also employed by the farriers. Latreille is of opinion that the modern meloë were the *Euprates* of the ancients, insects to which they attributed very noxious properties, supposing them to be fatal to the oxen that swallowed them.

Melolonthidans. The family of Coleopterous insects of which the May-chaffer or May beetle (*Melolontha vulgaris*) is the type.

Melon. The *Cucumis Melo* of botanists, a trailing annual, much cultivated for its grateful fruit in all Eastern countries, especially in Persia, Tartary, and North-West India. In this country they can be grown with success only by the aid of artificial heat, and the fruit forms one of the delicacies of our desserts. These are what are called Musk Melons, with a rich musky flavour in the red or green fleshed fruit. Water Melons, the produce of *C. Citrullus*, are a distinct race, less rich and sugary, but with more abundant juice, and hence highly prized in hot dry countries.

Melopaisite. A yellowish or greenish white Lithomarge, from Neudeck, in Bohemia.

Melpomene (Gr. *μελπομένη, the singer*). One of the nine Muses (Hesiod. *Theog.* 77); by later writers she is called the Muse of Tragedy.

Melusine. In the mediæval Mythology of France, a beautiful nymph or fairy, whose history occupies a large space in the popular superstitions of that country. She is represented as the daughter of Helmas, king of Albania, and the fairy Persine; and as having married Raymond, count of Toulouse, who built for her the magnificent castle of Lusignan (originally called Lusineem, the *anagram* of Melusine). Like most of the fairies of that period, she was doomed to a periodical metamorphosis, during which the lower part of her body assumed the form of a fish or a serpent. On these occasions she exerted all her ingenuity to escape observation; but having been once accidentally seen by her husband in this condition, she swooned away, and soon afterwards disappeared, none knew whither. But her form is said to be seen from time to time on the tower of Lusignan clad in mourning, and uttering deep lamentations; and her appearance was universally believed to indicate an impending calamity to the royal family of France.

Melyris (Gr. *μελύρις*, an insect mentioned by Nicander). A Fabrician genus of Coleopterous insects belonging to the section *Pentamera*, subsection *Serricornes* tribe *Malarodermi*, and constituting the family *Melyridæ* in the system of Latreille: in which it is characterised as follows: Palpi commonly short and fli-

form; mandibles emarginated at the point; body usually narrow and elongated; head covered at the base by a flat or slightly convex thorax; joint of the tarsi entire, and the terminal hooks unidentate or bordered with a membrane; antennæ usually serrate, and in the males of some species even pectinate.

Membrana Tympani (Lat.). The membrane which separates the internal from the external ear. The drum of the ear. [*E.A.R.*]

Membrane (Lat. *membrana*). The expansion of any of the tissues of the body into a thin layer. Anatomists generally enumerate three kinds of membrane; namely, the *mucous*, the *serous*, and the *fibrous*. The mucous membranes are those which line the canals of the body which are exposed to the action of air or foreign matters, such as the lining of the nose, tracheæ, œsophagus, stomach, intestines, &c. The serous membranes form the lining of the sacs or closed cavities, as of the chest, abdomen, &c. The fibrous membranes are tough, inelastic, and of a tendinous character; such as the dura mater, the pericardium, the capsules of joints, &c.

Memnon. In Greek Mythology, a son of Eos (the morning) and Tithonos (=Titan, a name for the sun), represented in the legend as a son of Laomedon and brother of Priam. As Tithonos was a prince of Troy, his son, the Ethiopian Memnon, had to take part in the Trojan war, in which he was slain by Achilles; but his mythical character is again shown by the tears of morning dew, which his mother sheds on his death, just as the big drops fall from the sky when Zeus weeps for the untimely fate of his son Sarpedon. At the intercession of Eos, Zeus raised Memnon from Hades to Olympus.

The name *Memnon* is by some supposed to be a general appellation or epithet, *Mei-amun, beloved of Ammon*. The famous statue called by the Greeks *Memnon*, at Thebes in Upper Egypt, which possessed the real or imaginary property of emitting a sound like that of a harp at the rising of the sun, is supposed to have been in the building called by M. Champollion the Rhamesseion, from its reputed founder Rhameses, or Sesostris, of which the stupendous ruins are still seen between Medinet-Habou and Kournah. (Champollion, *Lettres écrites d'Egypte et de Nubie*, p. 261.) The statue of black granite in the British Museum, already styled the brother of the younger Memnon, was found in the Rhamesseion. The real Memnonium was, however, probably the temple said to have been erected by Amenoph or Amenophth. (Champollion, *ib.* p. 303.)

Memoir (Fr. *mémoire*, from Lat. *memoro, I call to mind*). In Literature, two different species of composition are popularly designated by the terms *memoir* and *memoirs*. A short biographical notice of an individual, or a short essay on a particular subject (especially to accompany and explain a map, view, facsimile, or other representation of any object in art, &c.) is called a *memoir*. This name is parti-

MEMORIAL

cularly appropriated to papers read before scientific or literary societies. The account, by an individual, of his own life, accompanied with narratives and remarks respecting the personages and events of the times in which he lived, is termed his *memoirs*; being supposed, as the name denotes, to have been drawn up with the object of assisting his memory in reflecting on past events. In modern but incorrect diction, the life of a person by another is also termed his *memoirs*, if drawn up with a somewhat less regular arrangement, and containing more matter not immediately connected with the subject than the species of narration which we term a *life*. The French were the earliest, and have always been by far the most successful writers, in this branch of literature. Their historical memoirs, partly autobiographical, and partly the works of authors who had access to the papers and memorials of those whose lives they illustrated, form a complete series from the sixteenth century to the present time, and throw the greatest light on some portions of history; while their memoirs of persons celebrated in the ranks of literature and fashion are still more numerous and interesting. In the last century this branch of literature became so popular, that any distinguished writer who did not leave authentic memoirs of himself was sure to become the subject, after his death, of fabricated memoirs, published under his name; and this species of falsification, of which Voltaire then complained, appears to be now carried on as extensively as at any former period. The collections of historical memoirs edited in Paris by Petitot, &c., contain three series of historical memoirs relating to French history, and one of English memoirs, translated, illustrating the period of our great civil war and revolution. The latter undertaking was conducted by M. Guizot.

Memorial. In Diplomacy, a species of informal state paper much used in negotiation. Memorials are said to be of three classes. 1. Memorials in the form of letters, subscribed by the writer, and speaking in the second person as addressed to another. 2. Memorials proper, or written representations, subscribed by the writer, and with an address, but not speaking in the second person. 3. Notes, in which there is neither subscription nor address. Species of the first class of memorials are: circulars from the bureau of foreign affairs sent to foreign agents; answers to the memorials of ambassadors; and notes to foreign cabinets and ambassadors.

In English Law, the transcript of a document requiring registration, deposited in the registry, is so termed; e.g. memorial of an annuity.

Memory (Lat. *memoria*). The power or capacity of having what was once present to the senses or the understanding suggested again to the mind, accompanied by a distinct consciousness of past existence. The term is also employed, though more rarely, to denote the act or operation of remembering, or the peculiar

MENDICITY

state of the mind when it exercises this faculty, in contradistinction to the faculty itself. Various opinions have been propounded by metaphysicians respecting the nature and origin of the faculty of memory. Upon this point, however, it is not our intention to enter into any details, as this question is so mixed up with that of other faculties of the mind, and with metaphysical questions, as to be inseparable from them. [ASSOCIATION; IDENTITY, PERSONAL; PERCEPTION.] We may, however, remark, that the ancient Platonists and Peripatetics ascribed the faculty of memory to the common theory of ideas; that is, of images in the brain, or in the mind, of all the objects of thought; and in this opinion they were supported, with slight modifications, by many other ancient philosophers. Modern thinkers for the most part regard memory as depending on the law of association. There is no doubt that, more than any other of our mental faculties, it is affected by the physical condition of the body. [MNEMONICS.]

Memory, Legal. [IMMEMORIAL.]

Menaccanite. A variety of Titaniferous Iron occurring in grains and small angular fragments of an iron-black colour in Cornwall, in the bed of a stream near Menaccan.

Mendicant Friars. [ORDERS, MENDICANT.]

Mendicinity (Lat. *mendicitas*, the state of a mendicant or beggar). The condition of habitual beggars. One of the greatest curses which can afflict a civilised society is the prevalence of mendicinity; and it is very much to be regretted that the prejudices of excellent and humane persons have so constantly interposed, and still interpose, difficulties in the way of the adoption and enforcement of correct principles on this subject. For there are too many who persist in seeing in mendicinity only the natural expression of that indigence into which numbers are unhappily thrown by the inequality of property and uncertainty of employment prevailing in almost all communities; and who forget that the encouragement of it affords a premium to the idle, the artful, the criminal—to all or any, in short, except those really deserving sufferers whom it is the object of true charity to relieve. For the law of England, past and present, respecting mendicity, see VAGRANCY. Under the operation of this law, of the national provision of the poor laws, and far more than either the activity of English industry, mendicity has been commonly regarded as less extensive and public in England than perhaps in any other country. And, owing to that very circumstance, it is perhaps worse in England than in any other country; that is, the established mendicants are more connected with the criminal part of the population. Ireland was long unhappily celebrated for the prevalence of mendicity. The number of *destitute persons* in the island was estimated by Mr. Stanley in 1837 at about 80,000 (Nicholl's *Report on Poor Laws in Ireland*); the number of street mendicants in Dublin at nearly 1,000,

MENDIPITE

or almost *one-twentieth* of the population. Sir G. C. Lewis, following the evidence adduced before the Irish Poor Law Commission, divided the habitual mendicants into: 1. Wandering beggars, chiefly cripples, blind, maimed, &c. 2. Professional strolling beggars, who have no fixed domicile, and live constantly by mendicancy. 3. Town beggars, who live by mendicancy, but have a fixed domicile: these, he says, 'are generally known by those who relieve them, and their character is not on the whole very bad.' 4. Poor housekeepers, who are relieved by three or four neighbours, to whom their wants are known, but who would not resort to general begging. (*On Local Disturbances in Ireland*, 1835.) But the administration of the Poor Law, and still more, perhaps, the extraordinary change which has taken place since 1847 in the numbers and circumstances of the Irish population, have gone a long way towards obliterating this ancient evil. In France, *dépôts de mendicité* were first founded in 1787; a kind of half way between prisons and hospitals for mendicants. Their situation was rendered dependent on their good behaviour. These receptacles held 6,000 or 8,000 persons in 1789. In 1808, by a new law, *vagabonds*, mere vagrants, were distinguished from beggars, i. e. disabled persons, or other persons begging within their own arrondissement; and the *dépôts de mendicité* were established for each department; while under the Code Pénal, art. 174, mendicity was rendered penal. The *dépôts*, however, gradually fell into disuse. 'The road to mendicity,' says M. Siamondi, 'is now too wide and too easy; instead of calling on religion to smooth it, we should multiply as far as possible the resources of the poor, in order to prevent their being dragged into it.'

Mendipite. A native oxychloride of lead found in the Mendip Hills, Somersetshire, in white crystalline masses sometimes with a yellowish or reddish tinge.

Meneghinite. A mineral discovered by Professor Bechi in the silver-lead mines of Bottino in Tuscany, and named by him after Professor Meneghini. It is a double sulphide of lead and antimony.

Menilite. A brown and opaque variety of Opal, found in irregular nodules, which have sometimes a slaty structure, in tertiary strata near Paris; principally at Saint Owen and Menil-Montant in beds of adhesive slate.

Meninges (Gr. *μῆνις*, a membrane). The membranes which cover the brain are so called.

Meningitis. Inflammation of the membranes of the brain.

Meniscus. A lens convex on one side and concave on the other. [LENS.]

Menispermaceæ (Menispermum, one of the genera). A natural order of diclinous Exogens, typifying the Menispermal alliance, and known technically by the condition of their seeds, which are amphitropal and have a large embryo in a moderate quantity of solid albumen. They occur in the tropical woods of Asia and America, and consist of trailing shrubs, with

MENTHA

alternate simple or lobed leaves, and small dioecious usually racemose flowers. They are bitter and narcotic, some being poisonous. *Anamirta Cocculus* yields the *Cocculus indicus* seeds which are illegally used to give narcotic properties and a bitter flavour to malt liquor; *Jateorhiza palmata* is the bitter Calumba root; and *Cissampelos Pareira* is the tonic *Pareira brava*. The order is a somewhat extensive one. [COCCULUS INDICUS.]

Menispermic Acid. An acid contained in the berries of the *Anamirta Cocculus* (*Cocculus indicus*), where it exists in combination with *picROTOXIN*.

Menonites. The title by which the Anabaptists of Holland came to be distinguished, after they had put themselves under the guidance of Menno, a native of Friesland, who undertook to moderate the extraordinary fanaticism of those sectarians. (Mosheim, transl. ed. 1790, v. 490.) [BAPTISTS; ANABAPTISTS.]

Menobranchus (Gr. *μένω*, I remain; *βράχια*, gills). A Perennibranchiate amphibia, which retains the external gills.

Menopome (Gr. *μένω*, and *πάμ*, a lid). A Perennibranchiate amphibia, which retains the opercular aperture, but not the external gills.

Menorrhagia (Gr. *μήν*, a month, and *ρῆγμα*, I break). Flooding; immoderate menstrual discharge; hæmorrhage from the uterus.

Menstris Philosophicus (Lat.). A chemical or philosophical month, of which the duration is variously stated; it was generally considered as including three days and nights.

Menstruum (Lat. *menstruus*, monthly). In the language of the old chemists, some preparation or drug which could only operate effectually at a particular period of the moon or month; but the term is now used for any fluid substance which dissolves a solid body.

Mensuration (Lat. *mensura*, a measuring). Though this term literally signifies the act of measuring, it is usually employed to denote the branch of practical geometry which teaches the methods of calculating the dimensions and areas of figures, the volumes of solids, &c., from the measurement of certain lines or angles of the figures or solids, which supply the requisite data.

Every rectilinear plane figure may be decomposed into triangles; and hence the mensuration of such figures resolves itself into the determination of the sides or area of a triangle.

[TRIGONOMETRY.] Solids bounded by planes may in like manner be resolved into pyramids, and their contents consequently determined by the methods of elementary geometry. [PYRAMID.] The determination of the lengths of curved lines, the areas of plane surfaces bounded by lines which are not all right, of the areas of curved surfaces, and of the volumes of solids bounded by surfaces which are not all plane, requires the aid of the integral calculus. [RECTIFICATION; QUADRATURE; CUBATURE.]

Mentha (Lat.; Gr. *μένθη*). The genus of the Mints, several of which, as *M. Piperita*, *citrata*, *Pulegium*, *viridis*, &c., are used for culinary, medicinal, or perfumery purposes. [MINT.]

MENTHENE

Menthene. A liquid hydrocarbon obtained by distilling the crystallisable portion of peppermint oil, or *peppermint camphor*, with anhydrous phosphoric acid. Its formula is $C_{20}H_{32}$.

Mentum (Lat. *the chin*). In Mammalogy, this term is restricted to the anterior and inferior margin of the mandible, or lower jaw. The *mentum prominulum* is that which extends beyond the perpendicular line dropped from the upper margin of the lower jaw, the human species being an example; the *mentum absconditum*, prevalent in the majority of *Mammalia*, is that which cannot be distinguished.

Menu, Fastitutes of. The name given to the most celebrated code of Indian civil and religious law; so called according to the myth from Menu, Menou, or Manu, the son of Brahma, by whom it is supposed to have been revealed. The word, like the Teutonic *man*, comes from a root signifying first to *measure* and then to *think*; it reappears in the Cretan Minos, who is likewise a lawgiver.

The Hindus ascribe the laws of Menu to the remotest age; and many of the most learned Europeans are of opinion that of all known works there is none which carries with it more convincing proofs of high antiquity and perfect integrity. The Institutes of Menu embrace all that relates to human life; the history of the creation of the world and man; the nature of God and spirits; and a complete system of morals, government, and religion. The work, says Sir W. Jones, contains abundance of curious matter, with many beauties which need not to be pointed out, and with many blemishes which cannot be justified or palliated: it is a system of despotism and priestcraft; both, indeed, limited by law, but artfully conspiring to give mutual support. But the most striking features by which the code of Menu is distinguished are the rigour and purity of its morals. Many of its maxims have all the sublimity of the precepts of Christianity; to which, in fact, they bear a close resemblance, not only in the style of thought, but of expression. Thus, 'Let not a man complain, even though in pain: let him not injure another in deed or in thought; let him not even utter a word by which his fellow-creatures may suffer uneasiness.' Again, 'Let him bear a reproachful speech with patience; let him speak reproachfully to no man; with an angry man let him not in return be angry; abused, let him answer mildly.' The words of the Psalmist, 'The fool hath said in his heart there is no God,' are thus almost verbally rendered, 'The wicked have said in their hearts no one sees us: yes, the gods distinctly see them, and so does the spirit within their breasts.' The Institutes of Menu have been translated into the English and French languages: into the former by Sir W. Jones in 1794, into the latter by Des Longchamps in 1830 (Strasbourg). An edition of the original Sanscrit, together with Sir W. Jones's translation, was published at Calcutta in 1822-26 by Sir Graves Haughton.

MERCATOR'S PROJECTION

Menura (Gr. *μῦρος, strength; οὐρά, a tail*). A name invented by Dr. Shaw for a genus of birds peculiar to Australia, the true affinities of which have been the subject of much discussion among ornithologists. Cuvier observes that the *Menura*, or lyre-pheasants, evidently belong to the order *Passerina*, and approach the thrushes in their beak, which is triangular at the base, elongated, slightly compressed, and emarginate at the point. Two species at least are at present known, both of which are remarkable for an extraordinary sexual development of the tail feathers of the male. Of these there are three kinds: the twelve common ones, with very fine and widely separated barbs; two more in the middle, of which only one side is furnished with thickly-set barbs; and two external ones, curved in the figure of an S, or like the arms of a lyre, whose internal barbs, large and thickly set, form a kind of broad riband, while the external ones are very short, becoming longer only near the tip. The female has only the twelve ordinary quills.

Menyanthes (Gr. *μῦρος, and ἄθος, flower*). A genus of Gentianaceous plants with powerful tonic properties. The *M. trifoliata*, or Buckbean or Bogbean, a wild aquatic plant, with white flowers densely crested with hairs, was employed in medicine as a bitter, emetic, tonic, and diaphoretic.

Mephitis (Lat.). Any noxious exhalation; but more particularly applied to carbonic acid gas. Mephitis was the name of a Latin goddess or sibyl who was invoked by the Romans as their protectress against noxious vapours.

Mercaptan. A liquid composed of sulphur, carbon, and hydrogen, which has received the above name from its energetic action on mercury—*corpus mercurium captans*. (Zeise, *Annales de Chimie et Physique*, iv. 87.)

Mercator's Projection. A representation of the sphere on a plane which, on account of the facilities it affords for navigation, is universally adopted for nautical charts. Meridians and parallels of latitude are represented by systems of right lines at right angles to each other; equidistant meridians by equidistant lines, but equidistant parallels by lines whose distance apart increases with the latitude in such a manner that the rhumb or sailing course towards a fixed point of the compass (in other words, every loxodromic spiral) is represented on the map by a straight line. The method was invented by Gerard Mercator (his true name was *Kauffman*, of which Mercator is the Latin equivalent), a native of Rupelmonde in East Flanders, born in the year 1512. But, though Mercator gave his name to the projection, it does not appear that he knew the law according to which the distance of the parallels from the equator increases. The true principles of the construction were found by Edward Wright, of Caius College, Cambridge, who explained them in his treatise, entitled *The Correction of certain Errors in Navigation*, published in 1599, and

MERCENARIES

are as follows: Suppose one of the meridians on the globe to be divided into minutes of a degree; one of these, taken at any parallel of latitude, will be to a minute of longitude, taken on that parallel, as the radius of the equator to the radius of the parallel; that is, as unity to the cosine of the latitude, or as the secant of the latitude to unity. This proportion holds true on the map in this sense, that if a minute of the equator be taken as the unit of a scale, then a minute of latitude will be represented by the trigonometrical secant of that latitude. Hence, in the map, while the degrees of longitude are all equal, the degrees of latitude marked on the meridian form a scale of which the distances go on increasing from the equator towards the poles, each being (approximately) the sum of the secants of all the minutes of latitude in the degree. The numbers resulting from the addition of the secants of the successive minutes reckoned from the equator form a scale of meridional parts, which is given in all books of navigation. Landsmen may obtain a good general idea of the construction of Mercator's chart from the article on the subject in the *Penny Cyclopædia*. [MAP; PROJECTION.]

Mercenaries (Lat. *mercenarius*). The name given to soldiers who sell their services for money. In the earlier periods of the Greek republics, as in that of Rome, all the citizens were bound to serve, as such, and without pay; and there was nothing like a standing army. Such a force was, however, naturally maintained by the Greek tyrants; and the Athenians, in the time of their wealth, for a different reason hired foreigners into their service, whence the term *ἑτοῖοι* or *strangers* became almost equivalent to that of mercenary. The Roman citizens, it is said, began to receive pay as soldiers during the war which ended in the destruction of Veii; but mercenaries in the strict sense of the word were not employed by them till a much later period of their history. [CONDOTTIERI.]

Mercuriale. The first Wednesday after the great vacation of the parliaments, under the old French régime. On that day they met to discuss grievances and deficiencies, and to reprimand members for misconduct. Hence, an harangue of reproof is popularly termed in French a *mercuriale*.

Mercurialis. A genus of common weeds of the Euphorbiaceæ order, and having poisonous qualities. *M. perennis* is called Dog's Mercury.

Mercurius Dulcis. An old Pharmaceutical term for Calomel.

Mercury (Lat. *mercurius*, from *merx*, mercari, to traffic). A Latin god, of commerce and gain. His festival was celebrated on May 25, chiefly by merchants, who visited his altar and well near the Porta Capena at Rome. The statue of Mercurius Malevolus on the Vicus Sobrius, where he was propitiated with milk instead of wine, held a purse in its hand. Thus there is little or nothing in common between the Latin Mercury and the Greek Hermes, with whom the later Ro identified

MERCURY

him, although the Fætalæ refused to recognise the identity. [HERMES.]

Mercure. This metal is found in various parts of the world. Among the principal mines are those of Almaden, near Cordova, in Spain; Idria, in Carniola; Wolfstein and Morsfeld, in the Palatinate; Guanacavelica, in Peru. The principal ore of mercury is the *sulphide* or *native cinnabar*, from which mercury is separated by distillation, either with quicklime or iron-slings, or by simply burning off the sulphur. Mercury occurs *native*, in small globules, generally dispersed through the sulphide. It is also found as a *chloride*, *iodide*, and *selenide*, but these are rare ores: in combination with silver it constitutes *native amalgam*.

Mercury is a brilliant silvery-white fluid metal, whence the terms *hydrargyrum* (*ὑδρᾶργυρος*) and *quicksilver*. In chemical formulae it is represented by Hg, and by the atomic equivalent 100. It is liquid at all common temperatures, solid at -40° , and contracts at the moment of congelation. It boils at about 660° , but it emits vapour at all temperatures above 40° . Its specific gravity at 60° is 13.56, but in the solid state it exceeds 14. The specific gravity of mercurial vapour is 6.976. When mercury is pure, it is not affected by agitation in contact with air. When rubbed with sugar, chalk, lard, conserve of roses, &c., it is reduced to a grey powder, which consists of minute mercurial globules, blended with the foreign body. In well-made mercurial ointment, or blue pill, which is mercury rubbed down with conserve of roses, these globules should not be discernible by the naked eye.

Mercury and oxygen combine in two proportions, and form two oxides, both of them salifiable: a dioxide or suboxide, composed of 200 mercury and 8 oxygen; and a protoxide, composed of 100 mercury and 8 oxygen. The suboxide is obtained when finely levigated dichloride of mercury (calomel) is triturated with excess of lime water. It is a black powder, resolved by light or by heat into metal and oxide. It forms a distinct class of salts, which give black precipitates with the caustic alkalis.

The *protoxide* or *red oxide* is produced by heating mercury in a long-necked flask, open to the air, nearly to its boiling point. It becomes slowly coated with reddish brown scales and crystals, and is ultimately converted into a red crystalline substance, called in old pharmaceutical works *precipitatum per se* or *calcin'd mercury*. It may also be obtained by heating nitrate of mercury; and it is thrown down in the form of a yellow powder, when potash or soda is added to a solution of corrosive sublimate, or of nitrate of mercury. In this precipitated state it possesses certain properties in regard to solvents, which distinguish it from the crystalline oxide, of which it is considered an allotropic modification.

Mercury and Chlorine also combine in two proportions, and form a subchloride, and a chloride, formerly called *protochloride* and *bi-*

MERCURY

chloride; the old terms *calomel* and *corrosive sublimate* applied to these chlorides are distinctively convenient.

Subchloride of mercury, or calomel, composed of 200 mercury and 36 chlorine, is generally made by sublimation, from a mixture of the sulphate of the suboxide with common salt. The calomel vapour is received into a capacious condenser, in which it is deposited in a pulverulent form: it is afterwards carefully levigated, and washed in large quantities of distilled water.

Calomel is tasteless, and insoluble in water. Its specific gravity is 7.14. At a heat somewhat below redness, it rises in vapour, without previous fusion; but it fuses when heated under pressure. The density of its vapour is 8.2. [CALOMEL.]

Chloride of Mercury or Corrosive Sublimate, composed of 100 mercury and 36 chlorine (Hg Cl), is made by exposing a mixture of chloride of sodium and sulphate of mercury to heat in a proper subliming vessel; *corrosive sublimate* rises, and *sulphate of soda* is the residue; $\text{HgO}, \text{SO}_3 + \text{NaCl} = \text{NaO}, \text{SO}_3 + \text{HgCl}$. Chloride of mercury has an acrid nauseous taste, leaving a permanent metallic and astringent flavour upon the tongue: it is a powerful corrosive poison. Its specific gravity is 5.4. It is usually met with either in the form of heavy white semi-transparent and imperfectly crystallised masses, or in powder. It is soluble in about 20 parts of cold, and 2 of boiling water; and as the solution cools, it deposits quadrangular prismatic crystals. It dissolves in 3 parts of alcohol and in 4 of ether. When heated, it fuses and evaporates in the form of a dense white vapour, powerfully affecting the nose and mouth: the density of this vapour is 9.4: it is condensed in prismatic crystals on cold surfaces.

Corrosive sublimate is either decomposed by, or combines with, many organic bodies; some of them convert it into calomel, others enter into combination with it, forming permanent compounds. The applications of it to the preservation of anatomical preparations, and to the prevention of dry rot, illustrate these actions. The efficacy of a mixture of white of egg and water, in preventing or mitigating the poisonous effects of this substance, depends upon its direct combination with albumen. [DRY ROT.]

The *Iodides* and *Bromides* of mercury correspond in atomic composition with the chlorides. The iodide ($= \text{Hg I}$) is of a scarlet colour, but not sufficiently permanent for use as a pigment. The red *sulphide* of mercury has been above adverted to as the principal native compound or ore of this metal; it is largely manufactured, generally by heating mixtures of mercury and sulphur, and sometimes in the humid way by precipitation: that made in China is especially esteemed on account of its colour, but as a pigment it is not permanent. [CINNABAR; VERMILION.]

Cyanide of mercury is occasionally resorted

to as a source of hydrocyanic acid, and the *Fulminate* is largely manufactured for use in percussion caps. [FULMINATING MERCURY.]

Large quantities of mercury are used in the separation of gold and silver from their ores, and it is a metal of considerable importance in reference to its therapeutical applications. It is employed in the construction of barometers, thermometers, and some other philosophical instruments, and more especially in the manufacture of looking-glasses or mirrors, the *silvering* of which is effected by the application of an *amalgam of mercury* to the polished surface of the glass. The process is performed as follows:—

A single and perfect sheet of pure tinfoil, of proper thickness, and somewhat larger than the plate of glass, is spread upon a perfectly plane table of slate or stone: mercury is then poured upon it, and rubbed upon its surface by a hare's foot, or a ball of flannel or cotton, so as to form a clean and bright amalgam; upon this, an excess of mercury is poured, until the metal has a tendency to run off. The plate of glass, previously made quite clean, is now brought horizontally towards the table, and its edge so adjusted, as, by gradually and steadily sliding it forward, to displace some of the excess of mercury, and float the plate as it were over the amalgam, the dross upon its surface being pushed onwards by the edge of the glass, so that the mercury appears beneath it with a perfectly uniform, clean, and brilliant reflecting surface. Square iron weights, of 10 or 12 lbs. each, are then placed side by side upon the surface of the plate, so as entirely to cover it, and press it down upon the amalgamated surface of the tin; in this way the excess of mercury is partly squeezed out, and the amalgam is made to adhere, by crystallisation, firmly to the glass. The mercury, as it runs off, is received into a channel on the side of the table, which is slightly inclined to facilitate the drainage, and in about 48 hours the weights are taken off and the plate is carefully lifted from the table and set nearly upright, by which the adhering mercury gradually drains off, and the brilliant amalgam remains, perfectly and uniformly adhering to the glass.

The annual imports of mercury into this country are about 2,200,000 lbs., chiefly from Almaden; of this quantity only about one-eighth is retained for home consumption, the rest being exported chiefly to South America, the United States, and the East Indies, with smaller quantities to Russia, Belgium, &c.

MERCURY. In the Solar System, the planet nearest the sun. The mean distance of Mercury from the sun is 0.3870981, the earth's mean distance being taken as unit; it is consequently little more than a third of the earth's distance, and equal to about 36,000,000 miles. His mean sidereal revolution is performed in 87.969,258 mean solar days, and his successive oppositions or conjunctions take place at intervals of 115.877 mean solar days.

K K

MERGANSER

The orbit is inclined to the ecliptic in an angle of $7^{\circ} 0' 9''$; and its eccentricity is greater than that of any other of the old planets, being 0.206,515, the major axis being unit. Mercury being an inferior planet always appears in the neighbourhood of the sun; his greatest elongation, or angular distance from the sun, amounts only to $28^{\circ} 48'$; so that he is very seldom, when at his greatest distance from the earth, visible to the naked eye, and then only at sunrise or sunset. His apparent diameter varies from $5''$ at his superior conjunction to $12''$ at his inferior conjunction when nearest the earth. At a distance equal to the mean distance of the sun from the earth, the apparent diameter is $6.9''$. His true diameter, compared with that of the earth taken as unity, is .398, or about 3,140 miles. On account of the smallness of the planet and its proximity to the sun, it is difficult to distinguish any features on the surface. Mercury, like the moon and Venus, exhibits phases; and the planet is supposed to revolve about its axis in 24 h. 5 m. 28 s.; but the evidence on which this rests is far from conclusive. Mercury is sometimes seen to pass over the sun's disc. This can only happen when he is in one of his nodes nearly at the same time that he is at his inferior conjunction. The phenomena are of more frequent occurrence than the transits of Venus, but of far less astronomical importance. The two next transits will be visible in this country, and will occur at the following dates: 1868, Nov. 4; 1878, May 6. [PLANET.]

Merganser. [MERGUS.]

Merger. In Law, the destruction of a lesser estate in lands and tenements by the acquisition of a greater estate in the same, immediately succeeding, by the same party and in the same right. Thus an estate for years will merge in an estate for life, if there be no other intervening estate; and an estate for life in an estate of inheritance. So, if a landowner becomes entitled to a sum of money charged on the land, the charge will generally be merged. There is no merger of an estate tail.

Mergus (Lat. *a diver*). A Linnæan genus of Anserine birds, characterised by a beak thinner and more cylindrical than that of the ducks, and with each mandible armed at its margins with small pointed teeth directed backwards, like those of a saw: the upper mandible is curved downwards, at its extremity. The goosander (*Mergus serrator*) and the merganser (*Mergus Merganser*) are examples of this genus.

Merieux (Gr. *μῆσις*, a portion, and *καρπός*, fruit). In Botany, the half of the double fruit of an umbellifer.

Meridian (Lat. *meridies*, mid-day). In Astronomy, a great circle of the sphere passing through the poles of the earth's axis and the zenith of the spectator. It is the circle on which the latitudes of places are reckoned, commencing from the equator, which it intersects at right angles. [DEGREE.]

MERMAID

Meridian Altitude. The altitude, or height above the horizon, of any celestial object, when it crosses the meridian of a place.

Meridian, First. The meridian from which longitudes are reckoned. The choice of the first meridian is entirely arbitrary; and most nations reckon the longitudes from their capital or meridian passing through their principal observatories. Thus, in English works, the longitude is reckoned from Greenwich; in French, from Paris; in Russian, from St. Petersburg, &c. Ptolemy employed the Canary Islands, the French formerly reckoned from Ferro, and the Dutch from the Peak of Teneriffe. Mercator chose the island Del Corvo. [LONGITUDE.]

Meridian of a Globe or the Brass Meridian. A graduated circular ring, within which an artificial globe is suspended and revolves, and by means of which it is connected with the frame bearing the horizontal scale. Meridian lines are also traced on the globe itself, usually at 15° distance, or a difference of longitude corresponding to an hour of time. It is probable that these, with the parallels of latitude, suggested to Descartes the idea of *coordinates*, which he applied so successfully to connect algebra with geometry.

Meridian Line. A line traced on the surface of the earth, coinciding with the intersection of the meridian of the place with the sensible horizon.

Merino Sheep. A breed of sheep till lately peculiar to Spain, but now reared in Saxony, and particularly in Australia, chiefly for the superior fineness of their wool. The word *merino* signifies an overseer of pasture lands, and is applied to this breed of sheep, because, in Spain, they are kept in immense flocks, under a system of shepherds, with a chief as a head, and with a general right of pasturage all over the kingdom. The best flocks of Spanish merinos are found in Leon and Castille; of the Saxon variety, at Stolpen and Rochsburg; but merinos are to be found in North America, the Cape of Good Hope, and above all in New South Wales, which has become one of the principal wool-growing countries in the world. There are one or two flocks of pure merinos in this country; but the unfitness of the climate, and the high prices both of wool and of mutton discourage any attempt to displace the larger native breeds. [SHEEP.]

Merlon (Fr.). In Fortification, the part of the parapet between two embrasures.

Mermaid (Ger. *meer*, sea, and *magd*, maid). A fabulous creature; the fore part woman, the hinder half fish. The animals which, viewed at a distance, may have originated the idea of mermen and mermaids, are the cetaceous *dugong* and *manatee*: these have their fore fins rudely fashioned like arms and hands, and terminate behind in a fish-like tail. The nipples are pectoral; and they are often seen ascending to the surface to breathe, clasping their suckling young to the breast.

MEROPIDANS

Meropidans. The family of Insectorial birds of which the bee-eater (*Merops*) is the type.

Meros (Gr.). In Architecture, the plane face between the channels in the triglyphs of the Doric order.

Meroxene. A name given to the brilliant crystals of brownish-green Mica (*Biotite*) from Vesuvius.

Merulidans. The family of Dentirostral perchers of which the thrush (*Merula*) is the type. [THRUSS.]

Merulius. A genus of Fungi well known as comprising the species which produces Dry Rot. This plant is called *M. lacrymans*. Coniferous wood is very liable to be attacked by this destructive agent, but its attacks are not confined to such wood, other timber when it falls in its way being equally liable to destruction. It will sometimes penetrate even thick walls, to the destruction of the mortar. In wine-cellars it destroys shelves and laths, and creeps amongst the sawdust used for packing, ultimately attacking the corks and spoiling the wine. Hence sawdust should not be used in cellars liable to this pest; and if wood is any way used, it should be kyanised. [DRY ROT.]

Mesembryaceæ (Mesembryanthemum, one of the genera). A rather extensive but not very important order of perigynous Exogens of the Ficoid alliance. They are succulent herbs, abundant in South Africa and distinguished by their numerous conspicuous petals, and several consolidated carpels. Many of them are very beautiful.

Mesembryanthemum (Gr. μέσος, the middle; ἐμβρυον, embryo; and ἄνθος, a flower). A very large genus of succulent Cape plants, of which many species are conspicuous for the beauty of their flowers, which expand in sunshine, and close up in gloomy weather. They are chiefly interesting on account of the hygrometric quality of their fruit, which when wetted opens out into numerous radiating valves, and when dry contracts with force into a compact and apparently solid body. This fruit is sometimes called the Fig-marigold.

Mesencephalon (Gr. μέσος, and ἐγκέφαλος, brain). The natural primary division of the brain, which is usually encompassed by the parietal segment of the cranium, and consists of the lobe of the third ventricle, the optic lobes, with the appendages called the *conarium*, *hypophysis*, and in fishes the *hypocaria*. Chaussier gave the term *mesocephale* to an artificial combination of the pons varolii with the optic lobes, dissociating the one from the medulla oblongata and cerebellum, and the other from the lobe of the third ventricle. By some anthropotomists the term *mesocephalon* is used synonymously with that of *pons varolii*.

Mesentery (Gr. μεσέντερον). The membrane by which the intestines are attached to the vertebra; it is formed of a duplicature of the peritonæum, and supports the nerves and vessels of the intestine.

MESOZOIC

Mesitylene. A hydrocarbon = C_8H_{10} produced by the action of sulphuric acid upon acetone.

Meslin (Old Fr. mesler, to mix). A mixture of various kinds of grain.

Mesmerism. [MAGNETISM, ANIMAL.]

Mesne Process. Such process as intervenes between the beginning and end of a suit. It is opposed to final process, or that which takes place by way of execution after judgment. Imprisonment for debt on mesne process was formerly effected on the bare affidavit of one person, stating that another owed him 20*l.*, but except as regards absconding debtors was abolished by the Act 1 & 2 Vict. c. 110. [ARREST.]

Mesne Profits. The yearly rents, &c. of land held illegally, which are recoverable in an action of trespass by the lawful owner after he has recovered possession of the land.

Mesocarp (Gr. μέσος, and καρπός, fruit). In Botany, that part of a pericarp which lies between the epicarp and endocarp.

Mesocolon (Gr. μεσόκωλον). The mesentery of the colon: it is an extensive duplicature of the peritonæum.

Mesolabe (Gr. μεσολαβέω, to take by the middle). An instrument employed by the ancients for finding two mean proportionals between two given lines; these were required in the problem of the duplication of the cube. (See Eutocius *On the Works of Archimedes*, and the third book of Pappus.)

Mesolite (Gr. μέσος, and λίθος, stone; because it is intermediate between Natrolite and Scolecite). A lime-and-soda Mesotype.

Mesophloeum (Gr. μέσος, and φλόος, bark or rind). In Botany, the cellular layer of bark overlying the liber, and underlying the epiphloeum, i.e. the layer immediately beneath the epidermis.

Mesophyllum (Gr. μέσος, and φύλλον, a leaf). In Botany, the parenchymatous tissue forming the fleshy part of a leaf between the upper and lower integuments.

Mesothorax (Gr. μέσος, and θώραξ, the chest). In Entomology, the posterior segment of the alitrunk, which bears the posterior pair of wings and the third or posterior pair of legs.

Mesotype (Gr. μέσος, middle, and τύπος, type). The name given by Haüy to Natrolite, because the primary form of its crystals is intermediate between Analcime and Stilbite.

Mesoxalic Acid. An acid obtained by boiling a saturated solution of alloxanate of baryta, which is thus resolved into *mesoxalate of baryta*, and other products. This acid is crystallisable, and very sour and soluble. Its formula is $C_8H_4O_{10} \cdot 2HO$.

Mesozoic (Gr. μέσος, and ζωή, life). The name given by Professor Phillips to the middle of the three great geological periods, more usually denominated **SECONDARY**. The mesozoic group includes (1) the new red sandstone or triassic, (2) the lias, (3) the great series of the oolites, (4) the Wealden, and (5) the

MESPILUS

series, and is of great importance in England, owing to the many useful minerals which it yields. It is also rich in fossils, being remarkable for reptiles' bones, many of them indicating animals of singular forms and proportions. It is not the case, however, as once supposed, that reptiles first appear in mesozoic rocks, as they have been recently found in coal measures. Neither is this middle period without representative forms of animals of still higher organisation; as quadrupeds certainly, and birds probably, existed during the whole of it. The minerals include, besides limestones and cement stones very rich and extensive deposits of iron-ore, and abundant stores of rock salt and salt springs.

Mespilus (Lat.; Gr. *μέσπιλον*, the Medlar-tree). The botanical name of the genus of the Medlar. The common medlar is called *Mespilus germanica*. [MEDLAR.]

Mess (Lat. *mensa*, a table). In Military language, the public dinner prepared for the officers of a regiment or detachment, and to the support of which they are bound to contribute a portion of their pay. Generally speaking, only married officers are exempted from contributing to, and dining at, the mess; the rest preside over it in rotation, without respect to military rank. There is a small government allowance in aid of the expenses of the officers' mess. Messes for sergeants have now been universally established.

Mess. In the Royal Navy, the general meeting of the officers at the meals. In large ships there are the ward-room mess, gun-room mess, midshipmen's mess, and engineer's mess. In ships of the frigate class and smaller vessels, the ward room is wanting. The sailors are also divided into messes of eight to twelve men each, among whom one acts as cook and messman. Each officers' mess has its steward, who serves as caterer.

Messenger (Fr. messenger, from Lat. *missus*, sent) or **Voyol**. In Naval language, a hawser or small cable of about sixty fathoms in length, wound round the capstan, and employed to transmit the capstan's power to the great cable, which from its non-pliability would fail to bite so well on the barrel. As the messenger is wound on at one end it is wound off at the other, the loose end being nipped on to the cable lower down, so as to make the action continuous.

Messengers, King's. Certain officers employed in the secretary of state's department to convey despatches, either at home or abroad. They were formerly employed in serving the secretaries' warrants for the apprehension of parties charged with high treason, or other grave offences; and in such cases it was not unusual for them to detain their prisoners at their own houses. In the year 1713 the ambassador of the emperor of Morocco was taken into custody by a king's messenger, and released only after a lapse of six months.

Messiad. The name given to the only modern epic poem of Germany; the subject of

METAGALLIC ACID

which is the sufferings and triumph of the Messiah. It is written in hexameter verse, for which the German is, perhaps, better fitted than any modern language, and consists of twenty books. The publication of this poem procured for its author a great reputation; but posterity does not appear to sanction the high award pronounced on it by contemporaneous writers. The reputation of Klopstock among his own countrymen rests chiefly on his Odes; and it must be admitted that in all those parts of his epic poem into which a lyric spirit could be infused—in other words, whenever the feelings or the sympathies were to be excited—there are few poets, either ancient or modern, to whom he deserves to be postponed; but, on the other hand, the dignity and sublimity of his sentiments are not unfrequently disfigured by the pedantry and affectation of his style, and the tediousness of his episodes.

Messiah. An old Hebrew word, signifying the anointed or sacred, corresponding with the Greek word *χριστός*; and in this sense applied by Christians to the Saviour, as it was anciently applied by the Jews to their prophets, priests, and kings, who were all anointed when they assumed their office.

Message (Mod. Lat. *messuagium*). In Law, a message is said to be properly a dwelling-house with a small portion of land adjacent. It is now one of the general words used in the legal description of dwelling-houses with the land attached.

Mestizo. In Spanish America, the child of a Spaniard or creole and a native Indian. [MULATTO.]

Metabolians (Gr. *μεταβολή*, change). A subclass of insects, including all those which undergo a metamorphosis.

Metacarpal (Gr. *μετά*, between; *καρπός*, in the sense of the wrist). Belonging to the metacarpus, or that part of the hand which is between the wrist and fingers.

Metacentre. A term first applied by Bouguer to a certain point of a floating body upon the position of which the stability of the body depends. [HYDROSTATICS.]

Metacetone (Gr. *μετά*, indicating change; and acetone). One of the products formed during the distillation of a mixture of one part of starch or sugar with eight of quick lime; it is a colourless liquid, insoluble in water, but soluble in alcohol and ether, and of an agreeable odour. Its formula is C_6H_8O . It is converted by oxidising agents into *metacetic* (*propionic*) acid = $C_6H_8O_3 + H_2O$.

Metachlorite. A mineral resembling Chlorite, found in green aggregated crystals at Büchenberg in the Harz.

Metagallie Acid. When gallic acid is rapidly heated up to about 480° , carbonic acid and water are evolved, and a black product remains soluble in the alkalis, and forming insoluble compounds with many of the metallic oxides. This product has been termed *metagallie acid*.

METAGENESIS

Metagenesis (Gr. *μετά*, indicating *change*; and *γένεσις*, *birth*). The changes of form which the representative of a species undergoes in passing, by a series of successively generated individuals, from the egg to the perfect or imago state. It is contradistinguished from *metamorphosis*, in which those changes are undergone by the same individuals. The following is an example of metagenesis: The egg of the Medusa is developed into a *polype* which, assuming a form called *Strobila*, separates into numerous individual young Medusæ. The larval polype propagates other similar polypes by gemmation, each of which becomes a *Strobila*, and is resolved into numerous Medusæ. Thus there is a successive production of procreating individuals from a single impregnated ovum of a Medusa, according to the law of Parthenogenesis.

Metallic Colours. A term sometimes applied to pigments of mineral origin, to distinguish them from colours derived from the animal and vegetable kingdoms. Many metals yield coloured compounds capable of being employed as pigments; but chromium, copper, lead, and iron are especially distinguished for the valuable colours which they produce.

Metallic Tractors. Towards the end of the last century, Dr. Elisha Perkins, of Norwich in Connecticut, introduced a method of treating diseases by drawing over the affected part two small metallic rods made of different metals, which he called *metallic tractors*, and the operation was called *traction*. The use of tractors has been called *Perkinism*.

Metallochromes (Gr. *μέταλλον*, *metal*, and *χρώμα*, *colour*). When very thin films of peroxide of lead are deposited by electrolytic action upon polished steel plates, they give rise to those beautiful prismatic tints which Nobili first described under the above name.

Metalloids (Gr. *μέταλλον*, and *εἶδος*, *form*). A term sometimes applied to the inflammable non-metallic bodies, such as sulphur, phosphorus, &c., or sometimes to all the non-metallic elements. The metallic bases of the fixed alkalies and alkaline earths were at one time called metalloids, in consequence probably of their low specific gravity.

Metallurgy (Gr. *μεταλλουργία*, *I smelt or work metals*). The art of separating metals from their ores. Some of the principal metallurgic processes are described under the respective metals. Dr. Percy's *Metallurgy* is the most comprehensive English work upon the subject, and Phillips's *Metallurgy* is a useful compendium. See also Pérouze and Frémy, *Chimie Inorganique*, ii., and Dumas' *Chimie appliquée aux Arts*.

Metals (Gr. *μέταλλον*). The metals constitute a numerous and important class of elementary bodies: they are characterised by a distinctive lustre, by their opacity, and by their high conducting powers in respect to heat and electricity. They amount (including how-

METALS

ever, some of doubtful character) to 53 in number, and are enumerated in the following table, together with the abbreviations or *symbols* by which they are usually designated in works on chemistry, and their *atomic weights* in reference to hydrogen as unity:—

Potassium . . .	K	39	Copper . . .	Cu	63
Sodium . . .	Na	23	Lead . . .	Pb	104
Lithium . . .	Li	7	Thallium . . .	Tl	204
Cæsium . . .	Cs	133	Bismuth . . .	Bi	213
Rubidium . . .	Rb	85	Cobalt . . .	Co	59
			Nickel . . .	Ni	59
Barium . . .	Ba	69	Chromium . .	Cr	26
Strontium . . .	Sr	44	Vanadium . .	V	68
Calcium . . .	Ca	30	Tungsten . . .	W	93
Magnesium . .	Mg	12	Tantalum . .	Ta	183
			Niobium . . .	Nb	96
Aluminium . .	Al	14	Molybdenum .	Mo	48
Glinium . . .	G	7	Uranium . . .	U	60
Zirconium . .	Zr	34	Tellurium . .	Te	64
Thorium . . .	Th	60	Titanium . . .	Ti	24
Yttrium . . .	Y	32	Antimony . .	Sb	122
Erbium . . .	Er	?	Arsenic . . .	As	75
Terbium . . .	Tb	?			
Cerium . . .	Ce	48	Mercury . . .	Hg	100
Lanthanum . .	La	44	Silver . . .	Ag	108
Didymium . .	Di	48	Gold . . .	Au	197
			Platinum . .	Pt	99
Iron . . .	Fe	28	Palladium . .	Pd	54
Manganese . .	Mn	28	Rhodium . . .	Bo	53
Zinc . . .	Zn	32	Ruthenium . .	Ru	52
Tin . . .	Sn	59	Osmium . . .	Os	100
Cadmium . . .	Cd	30	Iridium . . .	Ir	99

The first five of the metals upon the preceding list are distinguished as the *metals of the alkalies*; their oxides are powerfully alkaline; they have an intense affinity for oxygen, and decompose water at all temperatures. The next four metals are the *bases of the alkaline earths*; with the exception perhaps of magnesium, they also decompose water at all temperatures. The ten succeeding metals, with the exception of aluminum, have been but imperfectly examined; they are generally designated as the *bases of the earths*. The following twenty-two metals have been sometimes divided into those which form *basic oxides*, and those which form *acids*; and they have been separated into other distinctive groups, having reference to the action of acids upon them, to their action upon water at high temperatures, and to the isomorphism of their salts; these characters, however, are not sufficiently definite; and as regards the basic or the acid character of their compounds with oxygen, several of them form compounds belonging to both classes. The last nine metals include those which have been particularly designated as *noble metals*; they are not changed by air or by water, and their affinity for oxygen is comparatively feeble: to some of these properties, however, osmium forms an exception.

PHYSICAL PROPERTIES.—A high degree of *lustre* is one of the leading physical characters of the metals, the colour of the light which they reflect varying with the nature of the metal and the number of reflections to which it has been subjected. In most cases it is nearly white, grey, or bluish: from gold it is yellow, and from copper red; but the intensities of these colours may be greatly increased by repeated reflection.

METALS

The *opacity* of metals is such, that when in very thin leaves, they transmit no light. Gold is so far an exception, that when beaten into leaves of a 200,000th of an inch in thickness it transmits green light, and if alloyed with silver, blue light. There are also other means by which extremely thin metallic films may be obtained, and which often exhibit a certain amount of transparency.

Hardness—Brittleness.—Few of the metals, when pure, are very hard; they are generally softer than steel. Lead may be scratched by the nail; and potassium at 60° is softer than wax. Some, such as antimony, arsenic, and bismuth, may be easily pulverised: others are brittle at one temperature, but malleable and ductile at another. Zinc, for instance, which at common temperatures is comparatively brittle, may be rolled and drawn into wire when heated up to 300°.

Malleability, or the capacity of being extended by hammering or rolling, belongs to some of the metals in a very remarkable degree. Common gold-leaf, for instance, is not more than a 200,000th of an inch in thickness; and three grains of the metal are sufficient to cover a square foot. Silver, copper, and tin, also admit of great extension under the hammer. In hammering and rolling, some of the metals become so hard and brittle as to require occasional annealing; in these cases they give out much heat. The following is the order of malleability: gold, silver, copper, aluminium, tin, cadmium, platinum, lead, zinc, and iron.

Ductility.—The malleable metals are also ductile; i.e. they admit of drawing out into wire. In this respect, gold, silver, platinum, and iron stand at the head of the list. A grain of gold may be drawn into 500 feet of wire. A wire of platinum, not exceeding a 30,000th of an inch diameter, has been obtained by placing it in the axis of a small cylinder of silver, and then drawing the compound wire in the usual way, and afterwards dissolving off the silver by nitric acid. The order of ductility is as follows: gold, silver, platinum, iron, copper, aluminium, zinc, tin, and lead.

Tenacity, or the power of supporting a weight without breaking, is an important property of the metals. Iron is at the head of the list, and lead at the bottom; but the respective tenacities are much influenced by the temperature at which the comparisons are made, the manner in which they are tested, and more especially by the process of annealing. A wire of unannealed iron, which sustained a weight of 26 lbs., only bore 12 lbs. after having been annealed; and a wire of copper which sustained 22 lbs. before annealing, was broken by 9 lbs. after annealing. The following metals are arranged in the order of their tenacities: iron, copper, palladium, platinum, silver, gold, zinc, tin, lead. The tenacity of iron compared with lead is as 25 to 1.

In the following table the figures represent

the number of pounds required to break wires one-tenth of an inch in diameter:—

Lead	27.7	Silver	187.1
Tin	34.7	Platinum	274.8
Zinc	100.8	Copper	302.2
Gold	150.7	Iron	548.8

The tenacity of a metal, with few exceptions, decreases in proportion as its temperature increases; but iron, though less tenacious at 212° than at 32°, is more so at 890° than at 212°.

Crystallisation.—Metals are susceptible of assuming the crystalline form. With many, this may be effected by fusion and slow cooling, and especially by suffering the melted metal to concrete externally, and then perforating the solid crust, and pouring out the liquid interior. The cavity so formed will be then lined with crystals: this mode of proceeding answers extremely well with bismuth, which furnishes a congeries of cubic crystals. When the metals are precipitated by each other, they often crystallise during their deposition, as in the precipitation of silver by mercury, and in that of lead by zinc. A stick of phosphorus immersed in a solution of silver becomes incrustated with metallic crystals. Gold is occasionally deposited in a crystalline form, from its ethereal solution. During the electrolysis of metallic solutions, especially when low powers are employed, beautiful crystals are also occasionally obtained.

The crystalline structure of a metal materially affects some of its other physical properties. Copper, silver, and even gold, become comparatively hard and brittle when in a crystalline condition; and the most brittle metals are those which most readily assume the crystalline form, such as bismuth and antimony. Even iron, which in one condition is fibrous, tough, and tenacious, becomes relatively brittle when it assumes even an approach to a crystalline structure; and this change in its condition is sometimes the result of changes of temperature, and shows itself in bars and axles which have been subjected to protracted friction and vibration.

Specific Gravity.—The specific gravities of the metals, or their relative densities, as compared with distilled water at the temperature of 60°, are shown in the following table; they include the lightest and the heaviest solids. The metal lithium is the lightest, and platinum the heaviest, of all known solids.

Osmium	21.40	Manganese	8.0
Platinum	21.15	Iron	7.8
Iridium	21.15	Tin	7.2
Gold	19.3	Zinc	7.1
Tungsten	17.6	Columbium	6.0
Mercury	13.5	Antimony	6.7
Rhodium	12.0	Tellurium	6.6
Palladium	11.8	Arsenic	5.9
Ruthenium	11.3	Chromium	5.9
Lead	11.4	Titanium	5.3
Thallium	11.8	Aluminium	2.6
Silver	10.5	Strontium	2.6
Bismuth	9.8	Glucinum	2.1
Cobalt	8.9	Magnesium	1.74
Copper	8.9	Calcium	1.6
Nickel	8.8	Sodium	0.97
Molybdenum	8.6	Potassium	0.86
Cadmium	8.6	Lithium	0.59

METALS

Relation of Metals to Heat.—The changes of bulk which metals undergo with changes of temperature are relatively greater than those of other bodies; but each metal has its peculiar rate of expansion, as shown in the following table, in which 1,000,000 parts of each metal are assumed to be heated from 32° to 212°:—

	Increase in length	Increase in bulk
Platinum . . .	1 in 1131	1 in 377
Palladium . . .	1 in 1000	1 in 333
Antimony . . .	1 in 923	1 in 307
Iron . . .	1 in 846	1 in 282
Bismuth . . .	1 in 718	1 in 239
Gold . . .	1 in 682	1 in 227
Copper . . .	1 in 582	1 in 194
Silver . . .	1 in 524	1 in 175
Tin . . .	1 in 516	1 in 172
Lead . . .	1 in 361	1 in 117
Zinc . . .	1 in 340	1 in 113

The expansion of glass is nearly the same as that of platinum, and hence wires of that metal may be welded into fused glass without inconvenience; but if we substitute a wire of another metal, its different rate of contraction tends to break the glass as it cools. So also a compound bar of iron and copper, or of platinum and silver, formed by riveting strips of the metals to each other, though it remains straight at the temperature at which they were riveted, becomes warped or curved when heated or cooled. The metallic thermometer, and the compensation pendulum or balance-wheel as applied to clocks and watches, are illustrations of the same principle.

The force exerted in this act of metallic expansion is so considerable as often to produce injurious effects when not adequately provided for, as in railways, bridges, water and gas pipes, and in the beams, columns, and roofs of buildings.

The expansion of a metallic bar has been successfully applied as a means of measuring high temperatures, as in *Daniell's pyrometer*.

That the metals are excellent *conductors of heat* is learnt by the rapidity with which heat passes from one end to the other of a metallic bar; and that the different metals thus transmit heat with different degrees of facility, is shown by comparative experiments. If, for instance, two similar bars of silver and of platinum be heated at one end, the silver will be more rapidly heated throughout than the platinum. Gold, silver, and copper are among the best conductors; then come iron, zinc, and tin; and lastly, lead. A consequence of this property of the metals is, that they communicate and abstract heat more readily than other bodies; that they feel hotter and colder than wood, or other bad conductors, though of the same temperature. If the thermo-conducting power of gold be assumed as = 100, that of silver will be about 98, of copper 90, of iron 38, of tin 30, and of lead only 18.

The *poor metals* are remarkable for their low power of emitting and of receiving *radiant heat*. A polished metallic vessel filled with

hot water, is a long time in cooling; and such a vessel containing cold water, and placed before the fire, is a long time in acquiring heat. When the polish is taken off, the radiating and receptive powers of such vessels are increased; but under all circumstances the metals are bad radiators. If we compare the radiating power of a surface coated with lampblack, with that of polished gold, silver, copper, or tin, it is nearly as 100 to 12; and all tarnished metals radiate better than those which are bright and clean.

Fusibility.—The metals are all susceptible of fusion by heat, but the temperatures at which they liquefy are extremely various. At higher temperatures than those required for their fusion, the metals are *volatile*, and many of them may be distilled in close vessels. Mercury is volatile at temperatures above 40°. A piece of gold leaf suspended over it in a stopped bottle becomes slowly whitened by amalgamation. Cadmium, potassium, sodium, tellurium, zinc, and magnesium, are volatile at a red heat, and arsenic below a red heat. Gold and silver are converted into vapour when exposed to intense heat; and most of the other metals evaporate under similar circumstances.

Although the melting points are mostly mentioned under the heads of the respective metals, it will be convenient to give in this place a table showing how some of the more important metals differ from each other, in regard to the temperature at which they pass from the solid to the liquid state. The metals are here arranged in two groups: 1, those which are fusible below a red heat (1000°); and 2, those which are fusible above this temperature. The metals not included in this list can be readily fused only under the oxy-hydrogen blowpipe:—

Fusible below a Red Heat.

Mercury . . .	40°	Bismuth . . .	500°
Potassium . . .	150°	Lead . . .	612°
Sodium . . .	200°	Zinc . . .	773°
Lithium . . .	356°	Antimony . . .	960°
Tin . . .	442°	Calcium . . .	1000°
Cadmium . . .	442°	Magnesium . . .	1000°

Fusible above a Red Heat.

Aluminum . . .	1750°	Gold . . .	2016°
Silver . . .	1873°	Cast iron . . .	2786°
Copper . . .	1996°		

Specific Heat of the Metals.—By the term *specific heat* is meant the quantity of heat required to raise equal quantities of different substances to the same temperature. If we thus compare water with *mercury* we find that the specific heat of water being = 1.000, that of an equal weight of mercury is only 0.033. The specific heat of water, therefore, or, in other words, its *capacity for heat*, is very great compared with that of the metals, as shown in the following table; from which it will also be seen that the specific heat of the metals increases with their temperatures, so that it requires more heat to raise them a given number of degrees when they are at a high than when at a low temperature. The specific heats are in all cases compared with water, as = 1:—

METAMECONIC ACID

	Between 32° & 312°	Between 32° & 573°
Iron	0.1098	0.1218
Zinc	0.0927	0.1016
Copper	0.0949	0.1013
Silver	0.0557	0.0611
Antimony	0.0507	0.0547
Platinum	0.0335	0.0355
Mercury	0.0330	0.0350

RELATION OF THE METALS TO ELECTRICITY AND MAGNETISM.—In respect to *electrical conduction*, silver is the best, and mercury the worst conductor. Assuming the electro-conduction of silver as =100, that of copper is about 92, gold 65, zinc 24, tin 14, iron 12, lead and platinum about 8, and mercury 2. These conducting powers are remarkably influenced, in some cases, by temperature. Thus, in reference to tin, if its conducting power at 32° be =16, at 212° it will only be =10; so that, in general, the lower the temperature of the metal, the higher its electro-conducting power. [MAGNETISM, TERRESTRIAL.] Metals which are bad conductors of electricity become most heated by an electric current, as is well shown by transmitting a current of electricity through a wire composed of alternate lengths of platinum and silver; the platinum only becomes red hot.

Magnetism.—The peculiarities of iron in respect to magnetism have been long known, as also its permanent retention by steel. When a bar of iron is suspended between the poles of a magnet, it is equally attracted by each, and places itself parallel to the magnetic axis. Some other metals are similarly affected, though in an inferior degree; but there are some which appear to be repelled by the magnetic poles, and which, when properly suspended between them, assume a direction at right angles to the magnetic axis, placing themselves *equatorially*. Faraday, who first observed these phenomena, terms such substances *diamagnetics*. He has shown that various solids, liquids, and gases include magnetic and diamagnetic substances [MAGNETISM]; and that, as far as the metals are concerned, they may be arranged in the following order:—

Magnetic		Diamagnetic	
Iron	Cerium	Bismuth	Silver
Nickel	Titanium	Antimony	Copper
Cobalt	Palladium	Zinc	Gold
Manganese	Platinum	Tin	Arsenic
Chromium	Osmium	Cadmium	Uranium
		Sodium	Iridium
		Mercury	Tungsten
		Lead	

Metameconic Acid. [COMENIC ACID.]

Metamerie (Gr. *μερά*, and *μερος*, *part*). A term applied in Chemistry to bodies having one and the same composition and atomic weight, but yet differing remarkably in certain of their properties, probably in consequence of dissimilar molecular constitution. Thus, formate of oxide of ethyle (formic ether) and acetate of oxide of methyle (methyl-acetic ether) may both be correctly represented by $C_2H_4O_4$, but the elements in each are no

METAMORPHIC ROCKS

doubt dissimilarly grouped, as represented in the following formula:—

‘Isomeric compounds, the equivalent numbers of which are identical, are said to be *metamerie*.’ [ISOMERISM.]

Metamorphic Rocks (Gr. *μερά*, and *μορφή*, *form*). The materials of the earth's crust beneath the soil are called by geologists *rock*, whether they are hard like limestone and granite, plastic like clay, or loose like sand; and of these rocks all that are not in the condition in which they were originally accumulated, must be regarded as changed, altered, or *metamorphosed*. The latter expression is technical, and means that a definite change has taken place in the structure of the material.

As, therefore, all mechanical rocks except coral limestones have originally been deposited from suspension or solution in water, and therefore in the form of mud, sand, or gravel of some kind, it becomes obvious, when we find sandstones and limestones, or compacted and bedded clays, containing bands, nodules, and crystals, that a change has passed over them. They are no longer mud, but have assumed a new existence and new conditions; in a word, they have become *metamorphic rocks*.

The term is not usually so widely extended, but it is clear that no line can be drawn. Some rocks are so little altered that we can hardly recognise the change, some are so much changed that we can hardly trace the original form. Very extensive metamorphoses can take place without obliterating the traces of organic origin.

More commonly, only those rocks are spoken of as metamorphic which show the last stage of a transition to crystalline structure, and to the condition called *plutonic* or *igneous*. Such are marbles, quartzites, slates, micaceous and other schists, and gneiss, all of these being rocks in which the evidences of original aqueous origin are nearly or entirely lost. Regarded in this light, metamorphic rocks form a class of rocks distinct from aqueous, from volcanic or recent igneous, and from plutonic or ancient igneous. So many doubtful rocks have, however, on further examination turned out to be metamorphic, that possibly all rocks not actually showing marks of igneous agency may be found to belong to this large and important group.

Metamorphic rocks, of which calcareous rock is the basis, are very varied. Actually unaltered limestone hardly exists as a rock, for this mineral (carbonate of lime), associated and mixed up with many foreign substances, very readily undergoes change, and tends to separate itself into concretions when buried with other minerals and water. The common chalk or limestone mud is not much altered, but it often contains shells converted into flint and veins with crystalline calc spar or crystalline silica.

METAMORPHOSES

Coral limestone not only has the interstices between the corals filled up so that all are cemented into a solid mass, but is often so far altered as to be partly crystalline. Shell limestones in the same way are compacted, cemented, crystallised, and sometimes parts of them are completely replaced by other mineral. Sandstones also are cemented, cracked, and the cracks filled with matter more or less crystalline. In these cases the marks of mechanical origin are by no means obliterated. But where fossils occur in rocks, it is often not the actual and original animal product that we see, but something like it, i.e. something into which it has been changed. It is not necessary here to discuss how or why these changes have taken place; it is enough to point out the significant fact. Change goes on whenever any mixture of mineral matter is buried in the earth and left exposed to ordinary influences. If buried deeply by the subsequent accumulation of other deposits, and thus brought within the influence of a more equable temperature, the changes that take place are extensive and fundamental.

In this way a complete conversion has sometimes taken place, fossiliferous strata having exchanged an earthy for a highly crystalline texture for a distance of a quarter of a mile from their contact with granite. That the mere contact of granite near the earth's surface has no power to do this, is clear from the fact that many limestones have rested unaltered close to granite for an indefinite period. Besides the conversion mentioned, dark limestones full of shells and corals have been turned into white statuary marble, and hard clays into claystone, mica slate, and hornblende slate, fossiliferous at a distance, but losing all trace of fossil near the metamorphosed rocks.

Metamorphoses (Gr. *μεταμορφώσεις*, *change of form*). The changes of form which the representative of a species undergoes in a single individual. The term has practically been restricted to the instances in which the individual, during certain phases of the change, is free and active, as in the grub of the chaffer, or in the tadpole of the frog.

Metaphor (Gr. *μεταφορά*, from *μεταφέρει*, *I transfer*). From the evidence furnished by many words Locke conjectured that, if all words could be traced back to their roots, 'we should find in all languages the names which stand for things that fall not under our senses to have had their first rise from sensible ideas.' [LANGUAGES.] The progress of philological science has proved not only that the conjecture of Locke is fully warranted by fact, but that what he with other philosophers regarded as a peculiarity of certain words, was really the peculiarity of a whole period in the history of human speech. During this period words had simply a material meaning; and men gave utterance to nothing beyond strictly sensuous impressions. This is clear on an examination of such words as *grace* and *immortality*; the former, now used to express the highest gifts of God to man, being traceable to a time when it

METAPHYSICS

expressed simply the brightness derived from fat or oil, and the latter to a time when it denoted anything which could not be pounded or ground. Hence 'no advance was possible in the intellectual life of man without metaphor;' but the metaphorical process was, according to Professor Max Müller, of two kinds, the radical and poetical. *Radical metaphor* is 'when a root which means to shine is applied to form the names not only of the fire or the sun, but of the spring of the year, the morning light, the brightness of thought, or the joyous outburst of hymns of praise.' In such cases, the word rises from the merely material or sensuous object to a mental conception which has a certain analogy with the sensuous object originally denoted by the word. *Poetical metaphor* is 'when a noun or verb, ready made and assigned to one definite object or action, is transferred poetically to another object or action. For instance, when the rays of the sun are called the hands or fingers of the sun, the nouns which mean hand or finger existed ready made, and were as such transferred poetically to the stretched-out rays of the sun. . . . What applies to nouns, applies likewise to verbs. A verb such as *to give birth* is used, for instance, of the night producing, or more correctly preceding the day, as well as of the day preceding the night. The sun under one name is said to beget the dawn, because the approach of daylight gives birth to the dawn, under another name the sun is said to love the dawn, because he follows her as a bridegroom follows his bride; and lastly the sun is said to destroy the dawn, because the dawn disappears as soon as the sun has risen.' The results of this process would be homonymy and polyonymy: by the first, objects originally quite distinct would receive the same name; the second would furnish a vast number of names to denote the same object. On these two conditions depends the growth of *ΜΥΘΟΛΟΓΙΑ*, which is 'but a part of a much more general phase through which all language has at one time or other to pass.' (Max Müller, *Lectures on Language*, second series, viii.)

Metaphosphoric Acid. A term by which some chemists designate the protohydrated phosphoric acid = HO, PO_3 . The salts of this acid are *monobasic*.

Metaphysics (Gr. *μετά; φυσίς*, *nature*). A word employed, in popular usage, to denote enquiries relating to objects which are not merely physical and sensible. It is a remark of Sir James Mackintosh, that 'the term *metaphysics* affords a specimen of all the faults which the name of a science can combine. To those who know only their own language it must, at their entrance on the study, convey no meaning. It points their attention to nothing. If they examine the language in which its parts are significant, they will be misled into the pernicious error of believing that it seeks something more than the interpretation of nature. It is only by examining the history of ancient philosophy that the probable origin of this name will be

METAPHYSICS

found, in the application of it as the running title of several essays of Aristotle, which were placed in a collection of the manuscripts of that great philosopher *after* his treatise on physics.' To which it may be added that the title of the works in question (*τὰ μετὰ τὰ φυσικά*) was not given, as far as is known, by Aristotle himself, but appears to have been first used by one of the later Peripatetics, possibly Andronicus Rhodius (s. c. 80).

Metaphysics, however, in the modern sense of the word, has been defined to be the science which regards the ultimate grounds of being, as distinguished from its phenomenal modifications. As a means of attaining this end, it considers the correlative of being, knowledge; and knowledge, not merely in reference to its *form*, as it is capable of law and regulation, for that is the province of logic—nor in regard to its history, and the successive stages of its development, which are the objects of psychology, or mental philosophy—but knowledge as it is in relation to being, or objective reality. Philosophers have not been satisfied with marking the resemblances of the appearances in nature, and the order in which they succeed each other, whether those appearances were outward and sensible, or internal and revived by observation of their own mental processes; they have not even been content with the discovery that their knowledge of phenomena was self-consistent, and obeyed certain determined or determinable canons or forms; they have felt that the highest end of science could then only be attained when all knowledge was perceived to depend on a one ultimate principle, which should demonstrate at once its consistency with itself and its absolute foundation in reality. That the science of this ultimate unity is that to which the greatest philosophers have with more or less distinctness assigned the name of metaphysics, the history of philosophy sufficiently proves.

As it would be impossible, for the purposes of the present work, to attempt either an analysis or a history of this branch of scientific investigation, the present article will be confined to a brief summary and nomenclature of the principal writers and schools of modern metaphysics, or psychology.

1. The scholastic writers of the middle ages, proceeding on the road which they conceived Aristotle to have indicated, regarded metaphysics, or the science of the mind, as the highest branch of philosophy, and made it the special object of their close but narrow investigation. Two great sects arose among them: (1) that of the Realists, who maintained (according to the philosophy attributed to Plato) the real existence of universal ideas or universals; (2) the Nominalists, who denied it, and taught that these universals were names only, invented and used for purposes of classification. [Logic.] To the first class belonged Thomas Aquinas, and, in general, the chiefs of what was esteemed the more orthodox scholastic philosophy; to the second, Abelard, Ockham, and others of less

celebrity. In the fifteenth century the disputes of the two sects produced violent quarrels, which were only put an end to by the more profound dissensions of the Reformation. Generally speaking, the innovators in religion adhered to the nominalist cause in philosophy (Luther, Melancthon, &c.); but the original controversy died away, to revive under new shapes and designations in modern metaphysical enquiries.

2. Omitting the bold, but not systematic, efforts of Campanella and some other Italian philosophers at, or soon after, the period of the revival of letters, we may proceed to France as the country in which modern metaphysical science was first entered on in earnest. Descartes (1596–1650) stands at the head of the French school; deriving the reality of things from the phenomena of thought, and therefore occupying the position of leader of what has been called the spiritualist, in opposition to the materialist, school. Pascal (1625–1664) was an independent thinker, but approaching the principle of Cartesianism; of which the chief supporter in France, and to a certain extent the reformer, was Nicolas Mallebranche, whose *Recherche de la Vérité* appeared in 1674. But it was developed in a more remarkable manner by a thinker of a higher order, who belongs to France by his mental education, although by birth a Dutch Jew, Spinoza (1632–1677). After the decay of the great Cartesian school, no metaphysician, strictly so called, of any great distinction appeared in France, until the philosophy of Locke had penetrated the thinkers of the eighteenth century. Bonnet (1720–1795), the Encyclopedists (Dalembert and Diderot), Cuvanis (1767–1807), and especially Condillac (1715–1780), reduced the science of mind, step by step, to complete materialism. In recent times, Victor Cousin, by his adaptation of Scotch and Kantist principles, and, still more, the great apostle of Positivism, Comte (although not directly a teacher of metaphysics), have, among many others, attempted in various ways to bring back the current of French opinion in the direction of spiritualism.

3. Omitting Leibnitz as a speculator of a more general class, John Christian Wolf (1679–1764) deserves the title of the founder of the German school of metaphysics. But its greatest name is that of Immanuel Kant (1724–1804). Rejecting, and powerfully combating, the hypothesis of Locke which deduced all knowledge from the senses, he endeavoured to establish in opposition to it that *philosophy of pure reason* (or *transcendental*) based on *a priori* grounds, which has since been carried so far by his admirers and followers in Germany and elsewhere. The greatest of these are the paradoxical Fichte (1762–1814), Schelling (1775–1854), and Hegel (1770–1831).

4. The history of metaphysical science in England can be nowhere studied in so concise and comprehensive a form as in Dugald Stewart's *First Preliminary Dissertation to the Encyclopædia Britannica*. Hobbes, Locke,

METAPLASM

Bishop Berkeley, and Hume, are the four great thinkers of the early period who, in various ways, and by widely different yet cognate trains of reasoning, established what is commonly called the *materialistic theory*; and, in doing so, became the founders of the French encyclopedist school already mentioned, and also promoted that popular development of thought and action which in recent times has changed the whole aspect of society. The Scottish or modern school: Reid (*Inquiry into the Human Mind*, 1764), Dugald Stewart himself, and Dr. Brown (*Lectures on the Philosophy of the Mind*) have been termed eclectic, as holding an intermediate place between the simple materialism of the former and the transcendentalism of the Germans. The last name to be mentioned in this rapid summary is that of Sir William Hamilton, whose system has been lately subjected to a rigid criticism by Mr. J. S. Mill. (*Examination of Sir William Hamilton's Philosophy*.)

Metaplasm (Gr. μεταπλασμός, from πλάσσω, *I form*). In Grammar, a general term, comprehending all those figures of diction which consist in alterations of the letters or syllables of a word; taking place in three ways—by augmentation, diminution, or immutation. 1. Augmentation at the beginning, *prosthesis*; in the middle, *epenthesis*; at the end, *paragoge*; to which may be added *diacresis*, adding to the number of syllables by the resolution of a diphthong. 2. Diminution at the beginning, *apheresis*; in the middle, *syncope*; at the end, *apocope*; by contraction of two vowels, *syneresis*. 3. Immutation, *antithesis*, signifying the change of one letter for another; *metathesis*, transposition of the order of letters. [See those letters.]

Metapophysis (Gr. μερά; ἀπόφυσις, *a process*). In Anatomy, the exogenous process commonly situated between the diapophysis and anterior zygapophyses: in the human skeleton it is best developed in the last dorsal and first lumbar vertebra; the metapophyses are developed more, and from more numerous vertebrae, in most of the inferior mammalia, arriving at their maximum of length in the armadillos, in which they equal the neural spines in length in the posterior dorsal and the lumbar vertebrae. They relate in these singular quadrupeds to the support of the carapace, the neural spines representing the *king-posts*, and the metapophyses the *tie beams*, in the architecture of a roof.

Metastasis (Gr. *change of position*). The transference or translation of a disease from one part of the body to another.

Metatarsus (Gr. μερά, and τάρσος, sc. *τοῦ ποδός*, *heel*). The instep is so called by anatomists.

Metatartaric Acid. A modification of tartaric acid produced when the latter is heated to 340° Fahr. Its salts are more soluble than those of ordinary tartaric acid. [TARTARIC ACID.]

Metathesis (Gr.). In Grammar, the transposition of the letters of a word, a process

METEMPSYCHOSIS

not unfrequently exhibited in the words of kindred languages, as in the German *ross*, English *horse*. [METAPLASM.]

Metaxite. A fibrous variety of Serpentine. The same name is given by Delesse to Chrysotile.

Métayer (Fr.; Lat. *medietarius*). A form of tenure peculiar to the south-western countries of Europe, in which the tenant pays a portion of the produce to the landlord, from whom he receives tools, stock, and seed. As the proportion paid was generally one-half of the produce, the name *métayer* was given to this kind of tenure, although the amount varies with the goodness of the soil and the quantity of stock supplied.

A kind of tenure closely analogous to *métairie* prevailed for a short time in this country during the latter part of the fourteenth and the beginning of the fifteenth centuries. Before this time, the lord almost invariably cultivated his estate by a bailiff, and the tenant farmer was practically unknown. After the great pestilence of 1348, the wages of labour increased so much, despite the various enactments made to check the rise, that it became generally no longer profitable to cultivate land by hired labour, and the estates were let in greater or smaller parcels to tenants on lease. As, however, the lords had stocks on hand, these stocks, with a certain amount of seed, were leased with the land to the tenant, the tenant covenanting to replace the stock at the expiry of his lease, or to pay a fixed sum in compensation for them. From obvious causes this temporary expedient in the history of English agriculture was soon abandoned, *métairie* was succeeded by farmers' rents, and finally by the yeomanry tenure of small proprietors; the wars of the Roses, and the gradual impoverishment of many among the ancient nobility, having contributed powerfully to the change, by breaking up the great, but generally scattered, estates of the chief proprietors.

Considerable difference of opinion has prevailed as to the economical effect of *métayer* tenancy. Arthur Young, who visited great part of France and Italy just before the French Revolution, speaks generally in disparaging terms of this form of tenure. On the other hand, Jones, Sismondi, and Mr. Mill have expressed themselves favourably of the results of this holding. In all probability, all are in the right. Before the era of the Revolution, the rights of the seigniors were far less defined, and their tenants were more liable to oppression. At present, however, it appears that the balance of advantage is on the side of the tenant, who holds in effect his lands in perpetuity, subject to the payment of a tax, analogous to a tithe, and like a tithe easily convertible into a money payment.

Mete-stick. On Shipboard, a measure used in stowing the cargo, in order to preserve proper levels.

Metempsychosis (Gr. μεταμψύχωσις). A Greek word denoting the migrations of the

METEMPTOSIS

soul through different successive bodies. The doctrine of the transmigration of souls has existed in the belief of various religious and philosophical sects from the remotest antiquity. It formed the leading doctrine of one of the most celebrated schools of philosophy in the whole heathen world [PYTHAGOREAN PHILOSOPHY]; it was said to have found many adherents in Egypt; but it is chiefly among the Indians that this doctrine has taken deep and permanent root. The Indian doctrine of *metempsychosis* rests on the supposition that all beings derive their origin from God, and are placed in this world in an altogether degraded condition, from which they all, but more particularly the human race, must either decline into still lower degradation, or rise gradually to a higher state, as they give ear to the vicious or the virtuous suggestions of their nature. It must be remarked, however, that the Indians make a wide distinction between the future destiny of those who have passed through life tainted by the usual vices and infirmities of human nature, and those whose lives have been spent in the constant discharge of religious duties. In the latter case, the soul does not pass through different stages of existence; 'but proceeds directly to reunion with the Supreme Being, with which it is identified, as a river at its confluence with the sea merges therein altogether. His vital faculties, and the elements of which his body consists, are absorbed completely and absolutely; both name and form cease; and he becomes immortal, without parts or members.' (Colebrooke's translation of extracts from the *Brama-Sutras*, in the *Transactions of the Royal Astronomical Society*, vol. ix.)

Metempsychosis. [PROEMPTOSIS.]

Meteorolite. [ÆROLITE.]

Meteorology (Gr. *μετεωρολογία*). The science of meteors, or the science which explains the various phenomena which have their origin in the atmosphere. Under the term *meteorology* it is now usual to include not merely the observation of the accidental phenomena to which the name of meteor is applied, but every terrestrial as well as atmospheric phenomenon, whether accidental or permanent, depending on the action of heat, light, electricity, and magnetism. In this extended signification, meteorology comprehends climatology, and part of physical geography; and its object is to determine the diversified and incessantly changing influences of the four great forms of natural force now named, on land, in the sea, and in the atmosphere. [See ATMOSPHERE; CLIMATE; and the various terms referred to under METEORS.]

Meteors (Gr. *μετέωρα*). A name given to any phenomena of a transitory nature which have their origin in the atmosphere. Meteors are of various kinds. Some are produced simply by a disturbance of the equilibrium of the atmospheric fluid, and are called *aërial meteors*. [WINDS; WHIRLWINDS.] A second

METEORS

class arise from the deposition of the aqueous particles which the atmosphere holds in a state of invisible vapour, and which are precipitated in consequence of a diminution of temperature, sometimes in a liquid and sometimes in a solid form. These are called *aqueous meteors*. [DEW; FOGS; HAIL; RAIN; SNOW; VAPOURS, &c.] A third class of meteors, or atmospheric phenomena, are caused either by the action of the precipitated aqueous particles dispersed in the atmosphere on the rays of light, or by the unequal heating of the air owing to which the rays of light are under certain circumstances reflected. [FATA MORGANA; HALO; MIRAGE; PARHELIA; RAINBOW.] A fourth class comprehends those which present the phenomena distinctive of combustion or incandescence. [ÆROLITE; AURORA BOREALIS; FIRE BALLS; LIGHTNING; SHOOTING STARS, &c.]

Meteors, Luminous. The generic name now given to those phenomena which result from the entrance into and combustion in our atmosphere of bodies known as *falling* or *shooting stars*, *bolides*, *meteors*, *ærolites*, and *meteoric stones*.

Recent investigations have shown that these phenomena are to be classed no longer in the domain of meteorology, as was so long supposed, but in that of astronomy, as they result from the entrance into our atmosphere of small bodies revolving round the sun like our earth, with this difference, that they do not travel singly, but are congregated in several rings—tangible orbits, as it were. The falls of shooting stars are due to the passage of our planet through one of these rings; whereas the meteors which appear from time to time, termed *sporadic meteors*, are bodies which, according to M. Faye, have not accomplished the immediate down-rush into our atmosphere, but have for a time been satellites to our earth until at length its attraction has proved too powerful for them.

Much of the recent progress is due to the labours of Mr. Alexander Herschel in this country, and Mr. Newton in America. Their cosmical origin has been placed beyond all doubt by the fact, among other considerations, that the star-falls observed from the earliest times and recorded in the Chinese annals have always occurred at the same day or nearly so of the *tropical year*, i.e. they have always happened in the same part of the earth's orbit. The dates at which at the present epoch star showers are expected are August 10 and November 11. In 1799 and 1833 the meteors were so numerous that it has been estimated that 34,000 fell per hour. Much alarm was caused among uncivilised people in consequence. Mr. Newton has estimated that the average number of meteors which traverse the atmosphere daily is 7,500,000. The meteors observed on the same date are generally found to issue from one point in the sky, called the *radiant point*, and astronomers have therefore concluded that the appearances are due to several of the rings to which we have before referred. We have one

ring which furnishes the August meteors, and another the November meteors, and the position of these rings in space is very different, for while one lies nearly in the plane of the earth's orbit, the other is inclined to it at a considerable angle.

The heights of shooting stars at their entrance and extinction are on the average seventy-three and fifty-two miles, with a probable error of three miles only. Their velocity is generally thirty-five miles a second. The weight of some of them has been estimated: shooting stars have been observed weighing two ounces, large meteors weighing two hundredweight. Thus the motion of the smaller masses is soon converted into heat sufficient to raise them to a state of incandescence, and we see them as shooting or falling stars. The larger ones can resist this vapourising action longer, as they approach the surface of the earth, and we see them as glowing coloured meteors; while the largest masses resist the action longer still—they complete their fall, perhaps burst, and spread masses of meteoric iron over large areas. The composition of *aérolites* is very constant, and their study has given rise to the most interesting speculations.

Metheglin (Ger. *meth*, *mead*). A beverage made of honey and water, fermented by the addition of yeast.

Methionic Acid (Gr. *μετρί*, and *θειον*, *sulphur*). An acid obtained by the action of anhydrous sulphuric acid on ether; althionic acid is at the same time formed.

Method. This word, from the Greek *μέθοδος*, which signifies a journey undertaken in quest of any object, or a way of attaining any end, denotes any mode of investigating truth. Thus we have the dialectic method, the inductive method, the analytical method, &c. [DIALECTICS; INDUCTION; ANALYSIS.]

Methodic Medicine. Medicine as practised by the methodic sect of physicians, of which Themison was the head. They endeavoured to reduce medicine to exact rules, and assumed that all diseases arose from constricted fibre.

Methodists. The body of Christians to whom this name is chiefly applied are the followers of John Wesley, the founder of this sect: hence called Wesleyan Methodists. But the term bears a more extensive meaning, being applied also to several bodies or sections of Christians who have seceded or withdrawn from the Wesleyan denomination.

The origin of the Methodist society took place at Oxford in 1729. After the Revolution, when the principles of religious toleration were recognised, the clergy of the Established Church were thought by some to have sunk into a state of lukewarmness and indifference. This alleged degeneracy was observed with pain by John Wesley and his brother Charles, while students at Oxford; and being joined by a few of their fellow-students, they formed rigid and severe rules for the regulation of

their time and studies, for reading the Scriptures, for self-examination, and other religious exercises. This observance of system in everything connected with the new opinions, as well as in their college studies, gained for them the appellation of *Methodists*; in allusion to the *methodici*, a class of physicians at Rome who practised only by theory. (Celsus, *De Medicina*.)

In the mean time Wesley took orders in the Established Church, and acted for a few months as assistant to his father, who was rector of Epworth, in Lincolnshire. After the death of the latter he was induced (1735), in company with his brother Charles and two other friends, to accept an offer to go to Georgia, in North America, to preach the Gospel to the Indians. On his return to England in 1737, Wesley officiated in several churches of the Establishment. But the higher ranks were offended at his declamatory mode of preaching; and the churches in general were soon shut against him. It was his desire to be allowed to officiate in the pulpit of his native church. But the circumstances to which we have referred threw his labours into a different, and ultimately an opposite, channel; and in short, without having at first intended it, he became the founder of the most numerous class of Dissenters in Great Britain.

Being thus virtually expelled from the Established Church, he preached in Dissenting chapels in London and other places where he could obtain admission. In course of time, and owing to the vast multitudes that crowded to listen to his ministrations, he adopted the expedient of preaching in the open air. He first formed his followers into a separate society in 1738, the year after his return from America, though he referred the establishment of Methodism to a prior date. Wesley, from this date, devoted his time and talents exclusively to the propagation of what he regarded the doctrines of the Gospel. His labours were chiefly confined to England; but he also paid visits to Scotland and Ireland, in the former of which his success was considerable. But while he confined his own labours to Great Britain and Ireland, he was not inattentive to the spiritual necessities of other countries, and, by means of a succession of missionaries, propagated his doctrines in America and many of the West Indian islands.

The success which attended his missionary exertions was not gained without obloquy, particularly in the United Kingdom. Owing to the liberality of the age, neither himself nor any of his missionaries were exposed to stripes and imprisonment; but all of them met with great opposition, and some of them were beset with mobs, and sometimes dragged through the streets as raving enthusiasts and disturbers of the public peace.

Finding his societies rapidly increasing, and having been refused assistance from the Established clergy, Wesley was induced to have

METHODISTS

recourse to lay preachers; an expedient which he was at first exceedingly averse to adopt, but which he afterwards found most efficient in promoting the triumph of his views. He was thus enabled to exercise superintendence over all his followers, and greatly to extend his sphere of action.

Wesley denied the doctrine of election, though he admitted that *certain* persons and churches have been elected, and that *great* events have been foreordained; and differed from the system of Calvin in regard to the extent of the Atonement, which he maintained was for all men; and held that repentance preceded faith. (In addition to Wesley's works, particularly his *Sermons*, see Benson's *Apology for the Methodists*; and Myles's *Chronological History of the Methodists*.) Wesley and his followers continued long after their separation from the Established Church to read the service of that church; nay, the practice was continued, in a few instances, after his death.

The Methodists have adopted a system of discipline and government which seems to partake as much of presbytery as of any other polity. Of this system, which is very complicated, the following are the leading features: Each society or congregation is divided into smaller bodies, called *classes*, each class embracing from twelve to twenty persons, one of whom is styled the *leader*. Each society has also a body of men called *stewards*, whose office is similar to that of deacon in the Established Church. The duties of leaders—namely, visiting the sick and holding religious intercourse with the members belonging to their class—are, in many respects, akin to those of lay-elders in the Presbyterian Church of Scotland. The leaders, stewards, and minister meet once a week (and this is called a *leaders' meeting*), on the religious business of the society; and to account for the funds received from the members.

A number of these societies united constitutes a *circuit*, while one of the ministers within the district is termed the *superintendent*. The ministers officiating in the circuit meet all the classes quarterly, and speak personally to each member. Those whose conduct is devoid of reproach receive a ticket, the chief use of which is to prevent imposture. After the conference with the classes another meeting (called a *quarterly meeting*) is held, consisting of all the ministers, leaders, and stewards in the circuit. On this occasion the stewards deliver their collections to a *circuit steward*; and everything relating to secular matters is publicly settled. At this meeting, also, the candidates for the ministry are proposed; and the stewards, after a definite period of service, are changed.

From five to ten or fifteen of the circuits, according to their extent, form a *district*, the ministers in which meet annually; the meeting being termed a *district meeting*. This assembly has authority 'to try and suspend

ministers who are found immoral, erroneous in doctrine, or deficient in ability; to decide concerning the building of chapels; to examine the demands from the circuits respecting the support of clergymen; and to elect a representative to attend and form a committee, four days before the meeting of the annual conference, in order to prepare a draught of the stations for the ensuing year. The circuit stewards are present at this meeting during the settlement of all financial matters. The judgment of the assembly is conclusive until the meeting of the conference, to which an appeal is allowed in all cases.

The *conference*, which is the supreme judicatory, and whose decisions are final, consists, strictly speaking, only of a hundred of the senior itinerant preachers, in terms of a deed of declaration executed by Wesley and enrolled in chancery. In this deed the meeting is termed 'the Conference of the people called Methodists.' But the conference is generally composed of the preachers elected at the previous district meetings to be their representatives, of the superintendents of the circuits, and of every minister who chooses to attend; all of them being allowed the same right of voting as the hundred, or legal conference. From this body all authority emanates; and by them all regulations to be observed throughout the whole Methodist connection are framed. They appoint ministers to their respective stations. The results of their discussions are annually published after each meeting, under the title of *Minutes of Conference*, which embody the laws of the society. (*General Rules of the Methodist Society*; Adam's *Religious World*, vol. iii. pp. 113-119.)

At the death of Wesley, in 1791, there were, in Great Britain and Ireland, about 300 itinerant preachers in connection with the new sect, and 1,000 local preachers—some of them, however, having very small congregations—and 80,000 members. But the Wesleyan Methodists have established foreign stations in Australia, Van Diemen's Land, &c.; and so rapidly have they increased, that the number of Wesleyan Methodists in 1850, both at home and abroad, amounted to upwards of two millions; and the total number of preachers, regular and supernumerary, was 6,000.

Various offshoots have taken place from the Wesleyan Methodists at various times; among the most important of which may be reckoned the followers of Whitfield, once the coadjutor, and afterwards the most powerful and eloquent opponent of Wesley, and supporter of Calvinism; the Methodists of Lady Huntingdon's connection, in whose chapels service is performed according to the ritual of the church of England; the Welsh Calvinistic Methodists; the Primitive Methodists [RANTERS]; the New Connexion Methodists; the Independent Methodists [INDEPENDENTS], &c. Some of these sects, particularly the Whitfieldians, are nearly allied in government and discipline to the Independents. (In addition

METHYL

to the works already quoted, see *Journal of John Wesley*; *Lives of Wesley*, by Coke, Moore, and Southey; *Nightingale's Portraiture of Methodism*.)

The total number of places of worship belonging to the Methodists of every class, and to isolated congregations of similar tenets, in England and Wales, amounted in 1851 to about 12,600. (*Census*.)

Methyl. The hydrocarbon radical of methylic alcohol. It is a colourless inflammable gas burning with a luminous flame, and is obtained from its iodide by the action of zinc at a high temperature under pressure, as also by the electrolysis of acetate of potash. Its *hydride* is MARSH GAS. Its *oxide* or *methylic ether* is gaseous at ordinary temperatures, but like its homologue, vinic or ethylic ether, it forms definite compounds with acids. The *hydrated oxide of methyl*, *methyl alcohol*, *wood spirit*, or *pyroxylic spirit*, is one of the products of the destructive distillation of wood: after rectification it is sent into commerce in a very impure state under the name of *wood-naphtha*.

Methylamine. Ammonia in which one atom of hydrogen is replaced by methyl. It is an inflammable gas greatly resembling ammonia in its chemical character. It may be formed by the action of iodide of methyl upon ammonia, and subsequent distillation with potash.

Methylated Spirit. Alcohol mixed with one-tenth of its volume of wood spirit. By this admixture its solvent powers are not deteriorated, and it may be used in the manufacture of varnishes, and for many other applications in the arts, while the disagreeable flavour communicated by the wood spirit prevents its being employed as a substitute for gin, or other intoxicating liquors. The excise regulations permit the sale of this article free of duty, which is a great boon to many of the arts and manufactures.

Methylene. A hydrocarbon composed of two atoms of carbon and two of hydrogen (C_2H_2).

Metis (Gr.). One of the small planets belonging to the group between Mars and Jupiter. [ASTEROID]

Metecæ (Gr. *μετοικαι*, *sojourners*). The resident aliens, who formed a large class of the inhabitants of Athens. They were distinguished from the few full citizens by many disabilities and burdens. They had no share in the administration of the state, and were precluded from the power of possessing landed estates. Each was compelled to purchase the protection which he received from the state by the payment of a small annual sum (*μετολαιον*), and to place himself under the guardianship of a citizen (*ποστέδρως*), who was his formal representative in the courts of law. They were generally engaged in mercantile and mechanical business.

Metonic Cycle (so called from Meton, its inventor, B.C. 432). A cycle of nineteen years,

METRIC SYSTEM

or, more accurately, of 6,940 days; at the end of which time the new moons fall on the same days of the year, and the eclipses return in nearly the same order. The reason of this is, that in nineteen solar years there are 235 lunations (with a difference of a few hours), and very nearly one complete revolution of the moon's nodes. The cycle was corrected by Calippus. [CALIPPIC PERIOD; CYCLE.]

Metonymy (Gr. *μετωνυμία*, *change of name*). In Rhetoric and Composition, a figure by which the name of an idea or thing is substituted for that of another, to which it has a certain relation. Thus, the effect is frequently substituted for the cause—*grey hairs* stands for *old age*: the abstract for the concrete—'What doth gravity' (i.e. the grave person) 'out of his bed at midnight?'—substance for quality, precedent for subsequent, &c.

Metope (Gr. *μετώπη*). In Architecture, the square space in the frieze between the triglyphs in the Doric order. It is either left plain or decorated, according to the taste of the architect. In the most ancient examples of this order, the metopes were left quite open. [ARCHITECTURE.]

Metopion (Gr.). An ancient ointment containing galbanum, which was formerly called *Metopium*.

Metoposcopy (Gr. *μέτωπον*, *a forehead*, and *σκοπέω*, *I view*). The art of divination by inspecting the forehead, treated of especially by the famous Cardanus. The signs of the forehead are chiefly its lines; but moles and spots are also supposed to have their particular meaning. The lines are under the dominion of their several planets.

Mètre (Gr. *μέτρον*, *measure*). In the classical sense of the word, a subdivision of a verse. The Greeks measured some species of verses (the dactylic, choriambic, antispastic, Ionic, &c.) by considering each foot as a metre; in others (the iambic, trochaic, and anapæstic) each *dipodia*, or two feet, formed a metre. Thus, the dactylic hexameter (the heroic verse) contained six dactyls or spondees: the iambic, anapæstic, and trochaic *trimeter*, six of those feet respectively. A line is said to be *acatalectic* when the last syllable of the last foot is wanting; *brachycatalectic*, when two syllables are cut off in the same way; *hypercatalectic*, when there is one superfluous syllable. [FOOT, in Prosody.]

MÈTRE. The French unit of length. [MEASURES.] It is somewhat longer than an English yard, being, in fact, equal to 39·37079 English inches. By an Act of Parliament passed in 1864, the *mètre* was rendered a legally valid measure throughout Great Britain and Ireland.

Metric System. A system of weights and measures adopted first in France, and now slowly superseding the systems in use in other countries.

The two most important points of this system are: firstly, that it is a *decimal system*, and secondly, that the units of length, superficies,

METRIC SYSTEM

solidity, and weight, are all correlated, two data only being used, the *mètre* and the weight of a cube of water the side of which is the $\frac{1}{10}$ th part of a *mètre*.

The system was suggested as long ago as 1628 by Jean Fernel, a physician of Henry II. of France; but the suggestion took a practical turn in 1790, when Prince Talleyrand distributed among the members of the Constituent Assembly of France a proposal, founded upon the excessive diversity and confusion of the weights and measures then prevailing all over that country as now over our own, for the foundation of a new system upon the principle of a single and universal standard. (*Report on Weights and Measures* by John Quincy Adams, p. 49, Washington 1821.)

A committee of the Academy of Sciences, consisting of five of the most eminent mathematicians of Europe—Borda, Lagrange, Laplace, Monge, and Condorcet—were subsequently appointed, under a decree of the Constituent Assembly, to report upon the selection of a natural standard; and the committee proposed in their report that the ten-millionth part of the quarter of the meridian of Paris should be taken as the standard unit of linear measure.

Delambre and Méchain were appointed to measure an arc of the meridian between Dunkirk and Barcelona, as Cassini had been appointed in 1669. They commenced their labours at the most agitated period of the French Revolution. At every station of their progress in the field-survey they were arrested by the suspicions and alarms of the people, who took them for spies or engineers of the invading enemies of France. The result was a wonderful approximation to the true length, and one in the highest degree 'creditable to the French astronomers and geometers, who carried on their operations, under every difficulty, and at the hazard of their lives, in the midst of the greatest political convulsion of modern times.' (*Essay on the Yard, the Pendulum, and the Mètre*, by Sir John F. W. Herschel, p. 19, London 1863.)

By means of the arc of the meridian measured between Dunkirk and Barcelona, and of the arc measured in Peru, in 1736, by Bouguer and La Condamine, the length of the quarter of the meridian, or the distance from the pole to the equator, was calculated. This length was partitioned into ten millions of equal parts, and one of these parts was taken for the unit of length, and called a *mètre*, from the Greek word *μέτρον* (a measure). (Briot's *Arithmétique*, translated by J. Spear, p. 152: Hardwicke, London 1863.)

If the arc of the meridian be calculated from the result of French researches, the *mètre* itself is equal, in English measurement, to 39·37079 inches; and, multiplying this length by ten million, the length of the quadrant of the meridian, when converted into feet, will be 32,808,992 feet. Sir John Herschel estimates

the length of the quadrant of the meridian at 32,813,000 feet; so that, according to his calculation, there is a difference between the French and the new estimate of the quadrant of 4,008 feet, and therefore the French length of the quadrant is $\frac{1}{10}$ th too short and the *mètre* is $\frac{1}{10}$ th of an inch less than the length of the ten-millionth part of the quadrant.

This error of $\frac{1}{10}$ th of an inch in the determination of the *mètre*, however, supposing it possible to establish it absolutely, does not make the metric system less complete or convenient; it is more than counterbalanced by the extreme simplicity, symmetry, and convenience of the system. Professor Bessel observed with respect to the *mètre*, that, in the measurement of a length between two points on the surface of the earth, *there is no advantage at all* in proving the relation of the measured distance to a quadrant of the meridian. (*Report of a Committee of the House of Commons on Weights and Measures*, p. 109, 1862.) Professor Miller of Cambridge, who quotes this remark, deems the error in the relation of the *mètre* to the quadrant of the meridian to be of no consequence; and he mentions another slight error in the metric system, discovered by recent research, relating to the density of water, which he gives in the following words of Bessel (from the *Populäre Vorlesungen*, by Professor Bessel, published in 1848, soon after his death):—

'The kilogramme (1,000 grammes) is not exactly the weight of a cubic decimetre of water. Many of the late weighings show that water at its maximum density has a different density from that which was assumed by the French philosophers who prepared the original standard of the kilogramme; but nobody wishes to alter the value of the gramme on that account.'

Two important principles form the basis of the metric system: 1. That the unit of linear measure, applied to matter, in its three forms of extension—viz. length, breadth, and thickness—should be the standard of all measures of length, surface, and solidity. 2. That the cubic contents of the linear measure, in distilled water, at a temperature of great contraction, should furnish at once the standard weight and measure of capacity.

Thus: 1. The unit of length was the *mètre*, as we have seen, the 10,000,000th part of a quadrant of the earth's surface.

From this we derive: 2. The unit of superficies—the *are*, a square *décamètre*. 3. The unit of capacity—the *litre*, a cubic *décimètre*. 4. The unit of weight—the gramme, the weight of a cubic *décimètre* of water.

The following tables, compiled by Mr. Warren de la Rue, will show the beautiful simplicity of this system—a simplicity arising from the decimal system, the correlation of the different units, and the uniform nomenclature adopted for the subdivisions and multiples of the units.

METRIC SYSTEM

Comparison of French and English Measures.

Length.					
	In English Inches	In English Feet = 12 Inches	In English Yards = 3 Feet	In English Fathoms = 2 Feet	In English Miles = 1,760 Yards

Such is the system which after much opposition was finally introduced into France by King Louis Philippe, and which sooner or later must probably become universal. In England it is already extensively used by scientific men, and in 1864 an Act was passed legalising its use in this country. The Act, however, is merely a permissive one.

The metric system of weights and measures has been adopted, not only by France, but in Italy (except the portion under pontifical government), Spain, Portugal, Greece, Belgium, and Holland; it has been partially received in Denmark and Switzerland, which adopts the half-kilogramme as the pound. The majority

of the states composing the *Zollverein*, or Customs League, in Germany, have expressed their approval of the metric system. The half-kilogramme has been introduced into all great mercantile operations in Austria.

At the International Statistical Congress, held at Berlin in September 1863, thirty-three nations of Europe and America were represented by statistical delegates, and the congress agreed to the following fundamental resolution on weights and measures: 'The adoption of the same measure in international commerce is of the highest importance. The metric system appears to the congress to be the most convenient of all the measures

L. L.

that could be recommended for international measures.'

A commission of the Imperial Academy of Sciences in St. Petersburg has recommended that such alterations should be made in Russian weights and measures as would put them in conformity with the metric system of France. Dr. Kupffer, a delegate from the Russian government, has declared that Russia would recommend the adoption of the pure metric system if Great Britain would take the lead. 'We wish England,' said Dr. Kupffer, 'to take the lead. England is a country of prior civilisation. Let England do it, and we are sure to follow.'

In the United States of America a committee has been appointed by congress to consider the subject of metric weights and measures; and the system has been adopted in Mexico, Chili, Peru, New Granada, Ecuador (to commence in 1866), Bolivia, Venezuela, and French and Dutch Guiana. For more information on this system, Mr. Dowling's Tables (Lockwood & Co.) should be consulted: the prefaces contain much valuable information.

Metronome. In Music, an instrument invented by Maelzel, and used to measure time, and to indicate the velocity with which a composition ought to be played. It has a small pendulum, which, being set in motion by clock-work, beats, audibly, a certain number of times in a minute; and this number may be altered by moving a sliding weight, and adjusted to varying degrees of quickness or slowness as required. It is now customary to mark, at the beginning of a piece of music, the number of beats per minute intended by the composer;

thus $\text{♩} = 60$ means that when the metronome is adjusted to 60 it will beat the time of minims for that piece, giving 60 minims in a minute.

Metropolis (Gr. *μητρος*, the mother city). 1. A parent state from which colonies have sprung; in which sense the word is uniformly employed by ancient Greek writers. 2. The chief city of a province in the later ages of the Roman empire. The Christian church having adopted the secular division of the Roman empire into provinces, the episcopal seat established in every such city, and the bishop of it himself, were termed metropolitan. In modern usage, the word is applied to denote the chief or capital city of an independent state.

Metropolitan. In Ecclesiastical History, a title applied to the prelate who presides over the other bishops in a province. The establishment of metropolitans took place at the end of the third century, and was confirmed by the council of Nice.

Metrosideros (Gr. *μητρος*, the heart of a tree, and *σιδηρος*, iron). Of this extensive Myrtaceous genus, one or two New Zealand species are remarkable for their hard close-grained timber. That of the Rata, *M. robusta*, is used for shipbuilding, and by the natives for making war clubs, paddles, &c.; that of the Kawa, *M. tomentosa*, called Firetree by the

colonists on account of the brilliancy of its flowers, is used for similar purposes; and that of the Aka, *M. scandens*, is called New Zealand Lignum Vitæ, on account of its hardness.

Mexican Gulf. A remarkable expanse of nearly enclosed ocean, which occupies, with the Caribbean Sea and the West Indian Islands, an area of more than two millions of square miles, shut in by the two Americas to the north and south, by Central America to the west, and almost enclosed by the long range of the Antilles towards the Atlantic. Its waters, which vary in depth from 500 to 1,000 fathoms, are very warm; and from it issues a remarkably warm, rapid, and important marine current, whose exact cause and origin cannot easily be traced.

The gulf of Mexico is the northernmost and innermost portion of this great sea. Enclosed on the north and west from the southern extremity of the peninsula of Florida to the extremity of the remarkable peninsula of Yucatan, and partly shut in by the western extremity of Cuba, it is reached by only two narrow openings, one communicating with the Caribbean Sea and the other with the Atlantic. The Bahama banks almost prevent access in the latter direction.

Although this gulf lies between 20° and 30° north of the equator, the oceanic warmth equator not only passes through it, but there attains its maximum temperature, the heat of the water being there estimated at 88½°, although it is not more than 80° at the equator, off the coast of Africa, near the hottest parts of that continent, and nowhere across the Atlantic rises above 84°. The hottest water of the Atlantic is, therefore, always in this sea—a fact which greatly influences the climate of America, and ultimately that of England. [GULF STREAM.]

Mezereon (Pers. *Madzaryoun*). The common name of the *Daphne Mezereum*.

Mezzanine (Ital. *mezzano*, middle). In Architecture, a story of small height introduced between two higher ones.

Mezzo Rilievo (Ital.). A term applied in Sculpture to the decoration executed in a middle style of relief, i.e. distinct from either the basso rilievo or the alto rilievo. The figures on the shaft of the Trajan's column, or on the column of the Place Vendôme, are examples of this style of sculpture. [RELIEF.]

Mezzo Soprano (Ital.). In Music, a low soprano.

Mezzotinto (Ital. half-tinted). A method of engraving on copper in which a burr is raised all over the plate, and subsequently scraped away in the parts that are intended to be left light. The modern engravers usually etch their plates before raising this kind of burr, which enables them to execute the work more rapidly, but less picturesquely, than in the old style.

This method of mezzotinto engraving was invented by Ludwig von Siegen in 1642. [ENGRAVING.]

Mi. The French and Italian name for the note corresponding to our E.

MIARGYRITE

Miargyrite. A sulphide of antimony and silver found at Bräunsdorf in Saxony.

Miasma (Gr. from *μᾶλον*, *I infect*). Infectious or contagious matter. The term is generally applied, under the name of *malaric miasma* (malaria of the Italians), to the infectious emanations from marshy lands and stagnant waters, which are peculiarly characterised by producing various forms of intermittent and remittent fevers. [MALARIA.]

Mica (Lat.). A term under which are comprised several varieties of a mineral generally found in thin elastic laminae, with a glistening lustre, and of various colours and degrees of transparency. It is one of the constituents of granite.

The micas have been divided into three groups: viz. Muscovite, Phlogopite, and Biotite. The *Muscovites*, which are confined to granite and other igneous rocks, are biaxial, and generally contain potash or lithia, and a small quantity of magnesia. The *Phlogopites* are also biaxial, though in a less degree than the *Muscovites*: they are found only in granular limestone and serpentine, and contain magnesia, and often only a small quantity of alkali. *Biotite* or *Magnesia Mica* is uniaxial, and contains large quantities of oxide of iron, magnesia, and potash.

The Micas are chiefly composed of silica, alumina, magnesia, potash, lithia, and some other bases.

In some parts of Siberia and elsewhere, Mica forms an article of trade, often known under the name of *Muscovy glass*.

Mica Slate or **Mica Schist**. A very abundant metamorphic rock—slaty, and essentially composed of mica and quartz. Mica sometimes forms the whole mass. Garnets are sometimes embedded as crystals in it, and form an integral part of the rock, which is then called *garnet schist*. Argillaceous matter is occasionally mixed with the mass, which thus assumes a slaty appearance.

Mica slate, abounding in garnets, and often sprinkled with red patches produced by decomposition, and becoming syenitic from the interspersed hornblende, is prevalent upon the banks of the Tay and about Dunkeld in Scotland; but it is in Glen Tilt that the geologist, both practical and theoretical, will find the most ample materials for the study of the association and junctions of this series of rocks.

In the immediate neighbourhood of Blair, the Tilt exhibits upon its banks a section of the rocks forming its bed; and the micaceous strata here and at the falls of the Bruar incline nearly at the same angle to several points of the compass, giving a curious confusion and interweavement to their assemblage.

The group of schistose rocks containing mica is large, and widely distributed wherever metamorphic rocks are found. Such rocks may belong to any geological period, but they have been formed at a great depth beneath the surface, and under enormous pressure. They are most usual in mountain districts, but abound

MICROLESTES

also in all places where an axis of elevation has brought up granite or porphyritic rock. The western extremity of all the British Islands, the western coast of France, and of the Iberian peninsula, and the flanks of the principal mountain chains, are the chief localities of these rocks in Europe. [GROSS.]

Micaceous Iron-ore. The name given to those kinds of Hematite or Red Iron-ore which possess a micaceous structure.

Micado. [TROCORN.]

Michael, St., Order of. A French order of knighthood, instituted by Louis XI. in 1469, in honour of St. Michael, the supposed ancient protector of France. It was for some time after its institution in high repute; but under Catherine of Medicis, who lavished it indiscriminately, it came to be held of no account.

Michaelite. A white, fibrous, and pearly variety of Opal found in the island of St. Michael, in the Azores.

Michaelmas. The feast of St. Michael the Archangel. It falls on the 29th of September, and is supposed to have been established towards the close of the fifth century; Brady says in 487. In England, Michaelmas is one of the regular periods for settling rents.

Michelia (after Pietro Antonio Micheli, a Florentine botanist of the eighteenth century). A genus of *Magnoliaceae*, consisting of large trees belonging to India and the Eastern Archipelago, distinguished from *Magnolia* by its axillary flowers, and other peculiarities. *M. Champaca*, the Chumpaka of the Hindus, and sacred to Vishnu, is commonly cultivated in India for the powerful fragrance of its flowers. The root is bitter, and used medicinally.

Microcline (Gr. *μικρός*, *small*, and *κλίνω*, *to incline*). A green and blue variety of Felspar, containing nearly equal quantities of potash and soda.

Microcosm (Gr. *μικρόκοσμος*, *a little world*). Man has been called so by some fanciful writers on natural philosophy and metaphysics, by reason of a supposed correspondence between the different parts and qualities of his nature and those of the universe.

Microcosmic Salt. The ammonio-phosphate of soda; it is obtained among the products of the evaporation of urine, and was formerly used as a blowpipe flux.

Microdactylus (Gr. *μικρός*, and *δάκτυλος*, *a digit*). A name proposed by M. Geoffroy for the short-toed genus of wading birds called by Illiger *Dicrolophus* [which see].

Microdon (Gr. *μικρός*, and *δούς*, *a tooth*). The name of a genus of extinct fishes, belonging to the thick-toothed or Pycnodont family, in the Ichthyological system of Agassiz.

Microlestes (Gr. *μικρός*, and *ληστής*, *thief*). A genus of marsupial mammalia, found in the upper triassic bone bed at Stuttgart, in Wurtemberg, and near Aust, in Gloucestershire. The minute crescent-shaped teeth of this animal exhibit the nearest affinity to those of the fossil *Plagiavulax* of the Furber strata, which was a small carnivorous marsupial, allied to

MICROLITE

Thylacoea. As far as present knowledge affords data, the *microlite* is the earliest representative of the mammalian class in this planet.

Microlite (Gr. *μικρός*, *small*, and *λίθος*, *stone*). A name for the columbate of lime found at Chesterfield in Massachusetts.

Micrometer (Gr. *μικρός*, and *μέτρον*, *measure*). An instrument applied to telescopes and microscopes for measuring very small distances, or the diameters of objects which subtend very small angles. A great number of contrivances of various kinds, and depending on different principles, have been employed for this purpose; but it will be sufficient to give a general description of some of the most useful or remarkable ones.

Wire Micrometer.—This instrument, when placed in the tube of a telescope, at the focus of the object-glass, presents the appearance represented in the annexed figure (fig. 1). A *a* is a spider's web line, or very fine wire fixed

Fig. 1.

perpendicular to A *a*; and, in order that the wire A *a* may be placed in any direction relatively to the meridian, there is an adjusting screw, which works into an interior toothed wheel, and turns the apparatus round in its own plane perpendicular to the axis of the telescope.

The method of using the micrometer is as follows: Suppose the object to be accomplished to be the measurement of the *angle of position* and distance of two very close stars; the telescope being set and kept on the objects, the micrometer is turned by its adjusting screw until the spider line A *a* coincides with the line joining the two stars, or *threads* them both at the same moment. The milled heads of the screws, which carry the two movable wires, are then turned until B *b* bisects one of the two stars, and C *c* bisects the other. The observation is now completed, and it only remains to ascertain the position and distance indicated by the micrometer. For the first of these purposes, the circumference of the micrometer is divided into degrees and minutes, and read by two verniers: this reading gives the position of A *a* in respect of the horizontal and vertical planes, and consequently the angle of position of the two stars. To find their distance, the head of the screw which carries one of the movable wires, for instance C *c*, is turned until C *c* coincides with B *b*; and the number of revolutions, and parts of a revolution required to effect the coincidence, gives the distance of the stars when the value of the *scale* of the micrometer is known: that is to say, when the number of seconds of space which correspond to one revolution of the

MICROMETER

screw is known. The screws must be made with great accuracy, and their heads are usually divided into sixty equal parts, representing seconds.

The value of the scale, or of a revolution of the screw, is obtained in the following manner: Set the two wires, B *b* and C *c*, apart to a certain number of revolutions, and place them in the direction of the meridian. Observe the transits of several stars of known declination over the wires; then multiply each interval of seconds by 15, and by the cosine of the star's declination; and, taking the mean, you have the seconds of space which correspond to a known number of revolutions of the screw. (See Appendix, by the Rev. R. Sheepshanks, to Professor de Morgan's *Explanation of the Gnomonic Projection of the Sphere*.)

Circular Micrometer.—This instrument, which differs entirely from the above, was first suggested by Boscovich, in the *Leipsc Acta* for 1740, and used by Lacaille in observing a comet in 1742; but seems afterwards to have fallen into disuse, until it was revived by Dr. Olbers, about 1798. The principle may be explained as follows: If the field of a telescope be perfectly circular (which may be effected by means of a diaphragm turned in a lathe), and if its diameter be determined from observation, the paths of two celestial bodies across the field may be considered as two parallel chords, which are given in terms of a circle of known diameter. The differences of the times at which two stars arrive at the middle of their paths will be their ascensional differences; and the distance between the chords, which is readily computed from their lengths, gives the difference of the declinations of the two bodies.

The most approved construction of the annular micrometer is that of Fraunhofer. It consists of a disc of parallel plate glass (fig. 2), having in its centre a round hole of about half an inch in diameter, to the edges of which a ring of steel is cemented and afterwards truly turned in a lathe. The disc being mounted in a brass tube, so that it may be accurately adjusted in the focus of the eye-piece, and

Fig. 2.

applied to a telescope, the steel ring is alone visible, and appears as if suspended in the atmosphere, whence the instrument is called the *suspended annular micrometer*. The advantage of this construction consists in the accuracy with which the moment of ingress or egress is determined, from the body being seen in the field of view before it comes up to the edge of the steel ring. The annular micrometer is conveniently used for comparing the place of a small star or a comet with that of a known star in nearly the same parallel of declination. (*Astronomische Nachrichten*, b. iv.)

Divided Object-glass or Double Image Micrometer.—This instrument is formed by dividing the object-glass of a telescope or microscope into two halves, the straight edges

MICROMETER

being ground smooth, so that they may easily slide by one another. A double image of an object in the field of view is produced by the separation of the segments; and, by bringing the opposite edges of the two images into contact, a measure of the diameter of the object is obtained in terms of the extent of the separation. From its being used to measure the diameter of the sun, this is usually called the *helometer*. [HELIOMETER.] Instead of a divided object-glass, Ramsden preferred a divided lens in the eye-tube, which form of the instrument is called the *dioptric micrometer*. The double image micrometer was suggested by Roemer, about 1678; but first brought into use by Bouguer, about 1748.

Micrometer by Double Refraction.—The Abbé Rochon conceived the ingenious idea of applying the principle of double refraction to micrometrical measurement. Conceive two prisms, ABC and BCD (fig. 3),

formed of the same crystal, and so disposed that the face AB of the first is perpendicular to the axis of the crystal, while, in the second, the axis is parallel to the line of the intersection of the two faces CB and CD, so that the axes of crystallisation of the two prisms are at right angles to each other. The prisms are placed in perfect contact, and cemented by mastic; and together form a plate of which the opposite sides are parallel. Now, suppose a ray of light MI to fall perpendicularly on the face AB; it will proceed through the prism ACB, in the same straight line IO, without being separated, because IO is parallel to the axis of the crystal. But when it arrives at O, and enters the second prism BCD, it will be separated into two: the ordinary ray will continue to follow the same direction IONP, because the refracting powers of the two prisms are the same; but the extraordinary ray will take a different direction OR (towards BD, if the crystal is attractive, as rock crystal; but towards AC, if the crystal is repulsive, as Iceland spar), and, on emerging from the prism at R, will be refracted in the line RS. The angle PTS of the inclination of the two rays after their emergence from the prism is constant for the same crystal, and must be determined by experiment.

Let us now conceive this apparatus to be placed in the tube of a telescope, of which O (fig. 4) is the object-glass and F the focus,

directed upon a distant object at D (as a planet), the diameter of which, m , is to be measured. Suppose the double prism at T': two images will be formed; the ordinary image at a , and the extraordinary image at b . By sliding the prisms along the

tube towards O, the distance between the images will be increased; by sliding them towards the focus F, it will be diminished; and if placed exactly in the focus, the two images will coincide. Let V denote the visual angle or apparent magnitude of the object, f the focal distance FO of the telescope, U the constant angle aTb depending on the prism, and D the distance FT: we shall then have the diameter of the image $= f \tan V$, and the distance $a b = D \tan U$. Now, if the apparatus be slid along the tube from T' to T, where the two images are in contact, then the diameter of the image will be equal to the distance $a b$; and we have, consequently, $f \tan V = D \tan U$. Here the quantities f and U are found by experiment; whence V, the angular magnitude of the object, becomes known in terms of D.

The prism micrometer, when constructed in the manner now described, has this important defect, that the extraordinary image is accompanied by the prismatic colours, especially if the angle to be measured exceeds a few minutes; and hence Rochon found that he could not use it for measuring the diameters of the sun and moon. But this defect has been ingeniously remedied by M. Arago, by simply altering the arrangement of the apparatus, and giving the double prism a fixed position out of the tube and before the eye-glass. By this disposition two images are formed at the focus, the centres of which are fixed points, whose distance depends on the refracting power of the crystal; and the contact of the images is produced by increasing or diminishing the magnifying power of the eye-glass, instead of altering the position of the prism. The magnifying power thus becomes the measure of the visual angle subtended by the diameter of the observed object.

Various modifications of the three principles now explained have been proposed; for details respecting which we refer to Brewster's *Treatise on New Philosophical Instruments*; to the article 'Micrometer,' in the *Encyclopædia Britannica*, by the same author; and to Dr. Pearson's *Introduction to Practical Astronomy*. Other plans will be found described in Herschel's *Outlines of Astronomy*.

The micrometer is an instrument of the utmost importance in astronomy, and one, in fact, to which that science is as much indebted as to the telescope itself. From a paper by Mr. Townley, in the *Philosophical Transactions* for 1667, it appears certain that a micrometer with a movable wire was first constructed by our countryman Gascoigne about the year 1640, and used by him for measuring the diameters of the moon and some of the planets; but as Gascoigne, who was killed in the civil wars in 1644, published no account of his invention, the instrument was entirely forgotten, and the merit of reinventing it, and bringing it into general use, belongs to the F. astronomer Asout, who published a description of it in 1667. Huygens, a few years previously, had contrived to measure the diameter of a

MICROMETER

planet by inserting in the tube of a telescope, at the focus of the object-glass and eye-glass, a slip of metal which covered exactly the image of the planet, and then deducing the diameter from the breadth of the slip, compared with the diameter of the field; and Malvasia had employed for the same purpose a reticle or network of fine silver wires, crossing each other at right angles, and dividing the field of the telescope into a number of equal squares. (For the history of the invention and successive improvements of the micrometer, see the notes by Mathieu to Delambre's *Histoire de l'Astronomie au 18me Siècle*, pp. 616 and 645.)

Micrometer for the Microscope, and Methods of Measuring.—The microscope micrometer may be made upon the same principles as the telescope micrometer. The instruments in use among microscopists are *Jackson's micrometer* and the *cobweb micrometer*. The first consists of a small glass plate, upon which lines are drawn equidistant from one another. This is inserted in the eye-piece, and so arranged that it may be moved across the field of vision by the aid of a screw. The value of each division being ascertained by placing objects of known dimensions, or lines drawn at known distances apart, in the field, the object to be measured is carefully placed against the first division, and the position accurately adjusted by the screw. The number of divisions to the width of the object may then be carefully read off.

The cobweb micrometer was invented by Ramsden, and the principle of its action is precisely the same as that of the wire micrometer. By turning the screw which approximates or separates the frames across which the cobweb threads are stretched, the slightest alteration of the lines can be estimated, and a difference even of $\frac{1}{1000}$ of an inch rendered appreciable.

Practically, however, there is some difficulty in obtaining measurements of very minute objects, by the use of micrometers of any kind, adapted to the eye-piece; for unless the body of the microscope be very firm, in which case it will be inconveniently heavy, it is almost impossible to adjust the micrometer without a slight disturbance of the body, and this slight movement may cause a measurement very wide of the truth; especially when the highest powers are used, for the value of each division of the micrometer becomes altered according to the power of the object-glass employed, and in the case of the high powers this value becomes enormously increased, and of course any error in the determination is increased in a corresponding degree.

In practice, the following will be found the most successful method of measuring objects in the microscope. It was first proposed by Mr. Lister. The stage micrometer referred to is simply a slip of glass, upon which lines have been ruled at the distance of $\frac{1}{1000}$, $\frac{1}{500}$, $\frac{1}{200}$, or $\frac{1}{100}$ of an inch apart. These stage micrometers are to be obtained of the opticians. The lines are scratched by a diamond point, attached to

MICROPYLE

a beautiful instrument, by which lines can be drawn at any distances apart with the greatest precision. M. Nobert has succeeded in drawing these lines so close to one another, that more than 100,000 would go in the space of a single inch; and the beautiful mechanism used for drawing these lines is so true, and the lines so clear, that they may be used as test objects for ascertaining the defining power of object-glasses.

In Mr. Lister's method of measuring, a camera lucida, or a neutral tint glass reflector, or a steel disc placed at an angle of 45° , must be adapted to the eye-piece, and the microscope placed horizontally, as in the position for drawing objects with the aid of the above instruments. In the field of the microscope is placed an ordinary stage micrometer, with the lines separated by thousandths of an inch, care being taken that the instrument is arranged at about ten inches from the paper; the lines, magnified by a quarter-inch object-glass, are carefully traced with a sharp-pointed pencil; the micrometer is then removed, and replaced by the object whose diameter is to be ascertained. The object is traced over the lines or upon another piece of paper, and compared with the scale by the aid of compasses. The lines may be engraved upon a slate, and their value affixed, so that any object may be at once measured. Of course a different scale is required for each power. Such scales may be made upon pieces of gummed paper, and one of them should be affixed to every microscopical drawing. In comparing the representation of the same object delineated by different observers, it will often be found that great confusion has arisen in consequence of the magnifying power of the object-glass not having been accurately ascertained; and an object stated by two different authorities to be magnified the same number of times, is nevertheless represented much larger by one than by the other. This discrepancy in most cases arises from the magnifying power of the glasses not having been accurately ascertained in the first instance. For further information on measuring objects in the microscope, the reader is referred to the works of Quekett, Carpenter, or Beale.

Microphone (Gr. *μικρός*, and *φωνή*, a voice). An instrument for increasing the intensity of low sounds, by communicating their vibrations to a more sonorous body, the sounds emitted by which are thus rendered more audible.

Micropyle (Gr. *μικρός*, and *πύλη*, a gate). In Botany, a perforation through the skin of a seed, over against the apex of the nucleus.

The hard envelopes of the ova of insects (Meissner) and many other animals also exhibit one or more openings or micropyles, through which the spermatozoa pass, and thus obtain access to the ovum. The micropyle is usually a funnel-shaped opening, exhibiting a great variety of markings in different species. (Allen Thompson's article 'Ovum' in *Todd's Cyclopædia of Anatomy and Physiology*, Supplement, p. 111.)

MICROSCOPE

Microscope (Gr. *μικρός*, and *σκοπεῖν*, *I view*). An optical instrument which enables us to see and examine objects which are too minute to be seen by the naked eye. Microscopes are single or compound, according to the nature of their construction; a single microscope being one through which, whether it consists of a single lens or a combination of lenses, the object is viewed directly; while a compound microscope is one in which two or more lenses are so arranged that an enlarged image of the object formed by one of them is magnified by the second, or by the others, if there are more than two, and seen as if it were the object itself.

Single or Simple Microscope.—This instrument is, for the most part, simply a lens or sphere of any transparent substance, which refracts the rays of light issuing from a small body placed in its focus, and gives them such a degree of convergency as is necessary for distinct vision. In order that the rays of light issuing from the several points of a very small body may produce a sensible impression on the retina of the eye, it is necessary that the object be brought very near the eye; but when this is done, the rays coming from its different points are so divergent as to produce only a confused image. Now, if a convex lens be interposed between the object and the eye, and so placed that its distance from the object may be a little less than its focal distance, the diverging rays issuing from the object are refracted by the lens, and enter the eye placed behind it, either parallel, or so nearly parallel as to afford distinct vision. The object is then seen in the direction of the refracted rays, and at the distance at which it could be distinctly seen by the naked eye; and consequently magnified in the ratio of the distance of distinct vision to the focal distance of the lens. This ratio is called the *magnifying power* of the lens; hence, for single microscopes, the magnifying power is equal to the distance at which a small object can be seen distinctly by the naked eye, divided by the focal distance of the lens; and, as the distance of distinct vision is constant (at least for the same individual), the magnifying power is inversely as the focal distance. If we suppose the distance which limits distinct vision, in respect of minute objects, to be five inches (which is about the average for good eyes), and the focal distance of the lens to be one inch, the object will be magnified five times in linear dimensions, and twenty-five times in superficial. If the focal distance is one-tenth of an inch, the magnifying power will be fifty in linear extent, and 2,500 in superficial.

A single microscope may be obtained very easily by piercing a small circular hole in a slip of metal, and introducing into it a drop of water, which will assume a spherical form on each side of the metal. Or a small piece of glass may be placed upon a small circle of fine platinum wire, from which a piece projects as a sort of handle, and melted in the flame of a spirit lamp, when a minute bead will be obtained;

some of these are so uniform as to make excellent simple lenses. The substance commonly used for microscopic lenses is plate glass; but they are sometimes formed of rock crystal, which is better. Flint glass, by reason of its great dispersive power, is unfitted for the purpose. The precious stones, as the garnet, ruby, sapphire, and diamond, have been proposed; but the numerous and skilful attempts of Mr. Varley and Mr. Fritchard have proved that the advantages arising from the greater refractive power of those substances are more than counterbalanced by their colour, reflective power, double refraction, and heterogeneous structure. The crystalline lenses of minnows and other small fishes give a very perfect image of minute objects.

When the object to be examined is of such magnitude as to subtend an angle of some degrees, the requisite distinctness cannot be given to its whole surface by an ordinary lens, in consequence of the confusion occasioned by the lateral rays; unless, indeed, the rays are only permitted to enter the lens through a very small aperture, whereby the quantity of light is greatly diminished. In order to remedy this inconvenience, Dr. Wollaston contrived a form of lens, to which he gave the name of *perspective lens*. Its construction is as follows: two plano-convex lenses or hemispheres are ground to the same radius, and between their plane surfaces a thin plate of metal, with a circular aperture, is introduced. The aperture which appeared to give the most distinct image was about one-fifth of the focal length in diameter; and, when the aperture well centred, the visible field was as much as 20° in diameter. A lens of this kind possesses the double advantage of having a very short focal distance, and very little spherical aberration. Dr. Wollaston's contrivance may, however, be improved upon in various ways; for example, by filling up the central aperture with a cement of the same refractive power as the lenses, whereby the loss of light from the double number of surfaces is avoided; or by grinding away the equatorial parts of a sphere of glass, so as to leave a deep groove all round it, in the plane of a great circle perpendicular to the axis of vision, and filling the groove with opaque matter. This last construction is called the *Coddington lens* (from the name of its proposer); and when executed in garnet, and used in homogeneous light, it is considered by Sir David Brewster to be the most perfect of all lenses, either for single microscopes, or the object-lenses of compound ones.

In using a single lens as a magnifier, it is always necessary that the light be made to pass through a very small aperture, in order that the object may be seen distinctly and without distortion. This necessity arises both from the spherical aberration and the chromatic dispersion of the light falling on the surface of the lens under an angle of considerable obliquity; and the consequence is that the amount of light admitted to the eye is so much

MICROSCOPE

nished that the object cannot be clearly seen. To remedy this inconvenience, Dr. Wollaston proposed a combination of two lenses, called, in consequence, a *microscopic doublet*, the optical part of which may be described as follows:

Fig. 1.

M and N (fig. 1) are two plano-convex lenses, whose focal lengths are in the ratio of 3 to 1, or nearly so, and placed one over the other, so that their plane sides are towards the object. The adjustment of the distance between the lenses is best

accomplished by trial; and they must, accordingly, be mounted so that the distance can be varied at pleasure. AB is a diaphragm or stop for limiting the aperture. Though it does not appear that the stop was contemplated by Dr. Wollaston, who makes no mention of it, the performance of the microscope depends much on its nice adjustment. It is obvious that as each of the pencils of light from the extremities of the object is rendered eccentric by the stop, and made to pass through the two lenses on opposite sides of the common axis, they are affected by opposite errors, which, in some degree, serve to counteract each other. This doublet, when correctly made, is infinitely superior to any single lens, and will transmit a pencil of from 35° to 50° without any very sensible errors. The original description, by Dr. Wollaston, is given in the *Phil. Trans.* for 1829.

The above construction has been improved upon by substituting two plano-convex lenses for N in the doublet, the plane side of the one being in contact with the convex side of the other, and the stop being retained between them and the third. This combination is called a *triplet*; and its advantage is, that the errors of the doublet are still further reduced by the greater approximation to the object, in consequence of which the refractions take place nearer the axis.

Another form of doublet, proposed by Sir John Herschel, is represented in the annexed

Fig. 2.

figure (2). It consists of a double-convex lens, whose radii of curvature are as 1 to 6; and of a plano-concave, whose focal length is to that of the other as 13 to 5, placed in contact with the flatter surface of the

former, and having its concavity turned towards the object. Many other combinations have been proposed, but those which have now been described appear to be the most useful.

When the magnifying power of the lens is considerable, and consequently its focal distance very small, it requires to be placed at the proper distance from the object with great precision; and, as it cannot be held in the hand with sufficient steadiness for any length of time, it requires to be mounted in a frame having a rack and screw, by means of which its distance from the object can be adjusted

with accuracy. Mirrors for collecting the light and throwing it upon the object are also necessary for many purposes.

Compound Microscope.—The simplest kind of compound microscope is formed by the combination of two converging lenses, whose axes are placed in the same straight line. The arrangement of the lenses, and the path of the rays, will be readily understood from

Fig. 3.

the annexed diagram (fig. 3). MN is the object-glass, which has a very short focal distance, and PQ the eye-glass. A small object ab being placed before the object-glass, a little farther from it than the focus of parallel rays, a reversed and enlarged image $a'b'$ will be formed at some distance behind MN. The lens PQ is placed at such a distance from MN that its principal focus is in the line at $a'b'$; consequently the rays of light from every point of the image $a'b'$ emerge nearly parallel from PQ, and to the eye at E the image $a'b'$ is magnified, as if it were a real object, into $a''b''$, and appears at a distance equal to the limits of distinct vision, which, as stated above, is about five inches.

The magnifying power of this microscope, or the ratio of $a''b''$ to ab , is found as follows: In the first place, if we assume d to denote the distance of the first image $a'b'$ from MN, and f the distance of ab from MN, or the focal distance of MN, we have this proportion, $a'b' : ab :: d : f$. In the second place, if l denote the limit of distinct vision, or distance of the second image $a''b''$ from PQ, and f' the focal distance of PQ (or distance of $a'b'$ from PQ), we shall also have $a''b'' : a'b' :: l : f'$. These two proportions, being multiplied together, give

$$\frac{a''b''}{ab} = \frac{d \cdot l}{f \cdot f'}$$

which, therefore, is the magnifying power of the microscope. It thus appears that the magnifying power is inversely as the product of the focal distances of the two lenses, and directly as the distance between them. The magnifying power will therefore be increased by increasing the distance between the object-glass and eye-glass; but a limit is soon placed to this increase by the indistinctness of the image, and, in practice, it is not advisable to make the distance of $a'b'$ from MN more than from five to ten inches. Some of the best modern object-glasses, however, bear a tube of very great length without much loss of definition. The object-glass may be separated from the eye-piece by twenty inches or more. Suppose the focal distance of MN to be $\frac{1}{4}$ th of an inch, and the distance of $a'b'$ from MN to be five inches, then $a'b'$ will be twenty times greater than ab ; and if the focal distance of PQ be half an inch, and the distance of $a''b''$ from PQ be five inches, then $a''b''$ will be

MICROSCOPE

ten times greater than $a'b'$, and, consequently, 200 times greater than ab ; or the magnifying power is 200.

The great defects of the microscope, when constructed in the manner now described, consist in the smallness of the field of view, and want of achromatism in the object-glass, in consequence of which the images $a'b'$ and $a''b''$ are fringed with the prismatic colours. For the sake of enlarging the field of view, a third lens, larger than either of the others, and called the field-glass, is usually interposed between the image $a'b'$ and the object-glass.

Of late years the compound microscope has been very much improved, and is now a most valuable form of instrument. It consists essentially of a tube about ten inches in length, at the upper end of which is placed the *eye-piece*,

Fig. 4.
Negative or Huygenian
Eye-piece for Compound
Microscope.

while to the lower the *object-glass* is fitted. The *negative eye-piece* invented by Huygens for telescopes is the only one in use for the microscope, and is composed of two plano-convex lenses arranged as in the figure. By this eye-piece the *image* produced by the object-glass, brought to a focus in the tube of the microscope, is remagnified and corrected before it reaches the eye of the observer.

The *object-glass* is the most important portion of the compound microscope; and as its errors are multiplied by the magnifying power of the *eye-piece*, it is most important it should be made as perfect as possible. The principles adopted in making object-glasses were discovered by Mr. Lister and fully described by him in the *Philosophical Transactions* for 1725. By the new process he was enabled to obtain a large and perfectly flat field, in which no light was admitted without sacrificing distinctness of definition.

The magnifying power of the object-glass may be made to vary by altering that of the *eye-piece*, or by increasing or diminishing the distance between the *eye-piece* and object-glass. Object-glasses are spoken of according to their

Fig. 5.
Arrangement
of Lenses in
Achromatic
Object-glass.

focal length, as the *inch*, *quarter*, *eighth*, *twelfth*, &c.; but the glasses of the same reputed focus of different makers vary much in magnifying power. The *inch* with the low *eye-piece* should magnify about forty diameters, the *quarter* about 200, and so on. The best achromatic object-glasses consist of three lenses, each of which is composed of a bi-convex and a plano-concave lens, made of glass of different degrees of refracting power. The arrangement is represented in the figure. Mr. Wenham makes the third or lowest glass single, and finds that upon this plan excellent defini-

tion is obtained in glasses of very high magnifying power ($\frac{1}{16}$), while the operation of making the lens is much simplified.

During the last few years lenses of very high power have been produced. In 1840 Messrs. Powell and Lealand succeeded in making a $\frac{1}{16}$ th, magnifying about 1,000 diameters; in 1860, a $\frac{1}{32}$ th, magnifying more than 1,600 diameters; and in October 1864, a $\frac{1}{64}$ th, magnifying between 2,000 and 3,000 diameters. Mr. Wenham, however, completed a $\frac{1}{16}$ th, which defined excellently, as early as June 1856. These very high powers are all excellent working glasses, and by their use important facts have been discovered. The difficulty of manipulation, preparing specimens, and covering them with thin glass, &c., is of course much increased, and no one should attempt to employ these very high powers until he is quite familiar with the use of lower ones.

Form of the Compound Microscope.—The forms of the compound microscope now in use are very numerous. Almost every maker modifies the general shape of the instrument and the arrangement of the adjusting apparatus in some particular. It is, therefore, impossible to describe the instruments even of the principal London makers, but it may be practically useful if the most important requisites of a good instrument are briefly enumerated. With reference to the optical part, the *inch object-glass* should magnify not less than thirty diameters, and the *quarter* not less than 200, when the lowest or *shallow eye-piece* is applied. The field should be well lighted, and the lines of delicate objects submitted to examination should be sharp and well defined; without coloured fringes when placed in the centre or at the circumference of the field. The mirror should be large (at least two inches in diameter), one side plane, the other concave; and it should be adapted to the body of the microscope in such a manner, that the distance from the object may be increased or diminished, while it is also necessary that it should possess lateral movement, in order that very oblique rays of light may be made to impinge upon the object.

With regard to the mechanical portion of the microscope, the adjustments should work smoothly, and an object placed in the field for examination should not appear to move or vibrate when the screws are turned. The body should be provided with a joint, so that it may be inclined or placed quite horizontally. The stage should be at least *three inches in length by two and a half in width*, and there should be a distance of at least an inch and a half from the centre of the opening in the stage, over which the slide is placed, to the upright body. The motion of the slide upon the stage, and all other movements and adjustments, should be smooth and even, without any tendency to a jerking or irregular action. (Beale's *How to work with the Microscope*, 3rd edition.) For cheap microscopes, perhaps the best mode of adjustment is that introduced by Mr. Lodd,

MICROSCOPE

who employs a chain movement instead of the rack and pinion usually adopted.

The only other form of compound microscope which calls for notice here, is the hand or pocket microscope, which consists merely of the tube of the instrument with the eye-piece and object-glass. To the lower extremity of the telescope tube is attached a very simple form of stage, permitting the specimen to be examined in every part. The necessary focusing is performed by a screwing movement of the tubes which slide one within the other. The instrument is used like a telescope, and is most useful for field work. This microscope can be packed in a small case with all the necessary pipettes, glass slides, thin glass, &c. required for instituting microscopical examinations. It can be made very cheaply, and is particularly adapted for general use in schools.

Necessary Apparatus.—Every microscope should be furnished with certain pieces of apparatus; in the larger microscopes many elaborate instruments are usually added, which, not being absolutely necessary for all work, are not enumerated here. The essential things are as follows: *A neutral tint glass reflector for drawing and measuring objects; a diaphragm, to the under part of which is fitted a tube to receive an achromatic condenser or polarising apparatus; a bull's-eye condenser; one shallow eye-piece and two object-glasses, a low one magnifying from twenty to forty diameters, and a quarter of an inch which magnifies at least 180 diameters; a stage micrometer, a Maltwood's funder, and an animalcule cage should also be supplied.*

These instruments should be conveniently packed in the case with the microscope. The polarising apparatus and the achromatic condenser are not absolutely necessary for a beginner, and can be purchased afterwards. The cost of a student's microscope without these last instruments, but including the other apparatus mentioned, in a well-made case, should not be more than six pounds; and if the microscope be mounted upon a cast-iron foot, instead of a brass one, it may be obtained for about a pound less, without its practical utility being in any way impaired.

Of examining and preparing Microscopical Specimens.—This is one of the most important matters connected with microscopical enquiry, for the appearances of an object vary greatly according to the manner in which it is illuminated and the refractive power of the medium in which it is immersed.

If peculiarities in the surface of an object only are to be examined, the light may be thrown down upon it by the aid of an ordinary condensing lens, or perhaps the ordinary diffused daylight or lamplight may be sufficient. An object looked at in this way is said to be examined by *reflected light*. Objects examined by reflected light may be opaque or transparent; but if we desire to ascertain the internal arrangement of a texture, the object is so arranged that light may pass through it. The

direct rays of a lamp or ordinary daylight may be employed, or if a stronger light be required, it may be obtained by bringing the rays to a focus upon the object by the aid of a concave mirror, or by a lens or system of lenses, as in the various forms of condensers fitted on to the microscope beneath the stage.

With regard to the media in which microscopic objects may be examined. The object may be mounted dry, being surrounded by air alone, or it may be immersed in water, serum, the fresh vitreous humour from the eye of an ox or sheep, or in media which refract the light more highly, such as syrup or glycerine, oil, turpentine, or Canada balsam. Glycerine and syrup have the advantage over the latter fluids, because, being miscible with water in all proportions, moist specimens may be immersed at once, and after time has been allowed for them to become fully saturated, they are ready for examination. All fruits and vegetables preserved in syrup will furnish the student with beautiful microscopic specimens. Objects to be mounted in turpentine, oil, or balsam must be dried first, or if moist subjected to a long and somewhat difficult process, by which the water is first expelled, and its place at last taken by the highly refracting fluid. Hard dry objects, such as hair, horn, nails, shells, bone, the hard coriaceous coverings of insects, and the dry parts of vegetables, may be mounted in these highly refracting fluids. Dr. Beale has recently introduced a new and uniform method of preparation adapted to objects of every kind. The preservative medium which he usually employs is the strongest glycerine made by Price and Company. (*How to work with the Microscope.*)

Reflecting Microscope.—The principle of the reflecting microscope

Fig. 6.

is very simple, and easily conceived. Suppose MN (Fig. 6) to be a concave speculum, and a small object to be placed before it at f . A reflected image of the object will be formed at F , where the rays issuing from each point of the object intersect each other, and magnified in the proportion of FM to fM . If the image at F is viewed with the naked eye, the instrument is a single reflecting microscope; but if the image is viewed through a refracting lens PQ (or a combination of lenses forming an eye-piece), by which the rays are made to converge towards the eye at E , it becomes a compound reflecting microscope.

The reflecting microscope was first proposed by Sir Isaac Newton in the form now described; but, on account of the impracticability of illuminating the object, it was long disused. It has, however, been recently revived, under a modified form, by Professor Amici of Modena, who places the object outside the tube of the microscope, below the line NF ; and, in order that an image may be formed in the speculum, the rays issuing from the object fall upon a small

MICROSCOPE

plane mirror placed at *f*, inclined to the axis of the speculum in an angle of 45° , whereby they are thrown upon the speculum in the same manner as if the object itself were placed at *f*. By this means the object can be illuminated with perfect facility. The concave speculum MN is ground into an ellipsoidal surface; the diagonal mirror is placed at the nearest focus *f*, and the image is consequently formed at the other focus *F*. The image at *F* is viewed with a single or double eye-piece, as in other microscopes.

Solar and Oxyhydrogen Microscopes.—The solar microscope is composed essentially of a mirror and two converging lenses. The plane metallic mirror, CD (fig. 7), reflects the sun's rays upon the lens MN, by which they are

Fig. 7.

concentrated upon the object *ab* placed in its focus. The object, being thus strongly illuminated, is placed before a second lens PQ (a little before the principal focus), by which the rays are rendered still more convergent, and produce a magnified image of the object upon a screen suitably placed at a distance of some feet behind the lens. The object is here supposed to be transparent; if opaque, the light must be thrown upon it in such a manner as to be reflected by it to PQ. The mirror and lens MN are placed in the hole of a window shutter in a darkened room; and the mirror must be movable, in order that the sun's rays may always fall upon it under a proper angle to be reflected to the lenses. But the solar microscope is now almost entirely superseded by the *oxyhydrogen microscope*; so called because the illumination, instead of being produced by the sun's rays, is produced by burning a small piece of lime or marble in a stream of oxyhydrogen gas. In this case the plane mirror (C) becomes unnecessary; and instead of the lens MN a concave speculum is employed, in front of which the ball of lime is placed, and an intense light thus thrown upon the object *ab*, the rays from which are brought to foci upon the screen by the lens PQ. For full details respecting the management of this apparatus, which forms a very popular exhibition, the reader is referred to Goring and Pritchard's *Micrographia*. Very perfect oxyhydrogen lanterns with achromatic lenses are now made, which are exceedingly valuable for class teaching. Photographs may be taken of the most delicate objects, and the negatives thus obtained remagnified in this instrument with the best results. In this way the structure of the most beautiful and minute objects may be rendered evident to a large number of people. Mr. How, of Foster Lane, and Mr. Highley, of Green Street, Leicester Square, have brought this plan of illustration to great perfection.

MIDDLE LATITUDE SAILING

For descriptions of the various kinds of microscopes, see Brewster's *Treatise on New Philosophical Instruments*; *Encyclopædia Britannica*, art. 'Microscope'; Todd's *Cyclopædia*, art. 'Microscope'; *Micrographia Dictionary*; Quekett *On the Microscope*; Carpenter, *The Microscope and its Revelations*; Beale, *How to work with the Microscope*, and *The Microscope in Medicine*.

Middle Ages. A term usually employed to denote, somewhat vaguely, a space of several centuries in European annals, intervening between what are called the ancient and modern periods of history. The centuries between the ninth or tenth and the end of the fifteenth after Christ are generally comprehended under this loose denomination. In his work on the *Middle Ages*, Hallam has assumed as his period of commencement the conquest of Gaul by the Franks, about A.D. 500; and, for his conclusion, the invasion of Italy by Charles VIII., about 1500. With reference to the affairs of the Greeks and their Oriental neighbours, he places, as the most convenient limit between ancient and modern history, the era of Mohammed.

Middle Eocene. The subdivisions of the middle Eocene in the English series are altogether different from those met with in France, where the deposits are richest in fossils and most characteristic. The following subdivision will enable the reader to understand this. The details will be found under various headings.

London and Hampshire Basins		Paris Basin	
	{	Sables Moyens	Freshwater
Barton clays		Calcaire grossier and glauconie grossière	Upper flags
Bracklesham sands			Freestone
Lower Bagshot sands			Greenish
			Lits coquilliers and glauconie

It is chiefly if not entirely the middle and lower part of the great Eocene series that contains the NUMMULITIC FORMATIONS, spread over a large part of the western world; and perhaps the most distinct and important of any beds of the TERTIARY PERIOD [which see]. The Claiborne beds of the state of Alabama in North America are also the equivalents of our Bracklesham beds, and contain many interesting fossils. Part of the basin of the Danube, with the lignite of Hungary and beds of true coal, occupy a similar position, although the Vienna basin is, in fact, of the middle tertiary or miocene period. Much of the brown coal of other parts of Germany belongs to this or the immediately overlying division of the tertiaries. [Eocene.]

Middle Latitude Sailing. In Navigation, a method of converting the departure (or distance on the parallel) into difference of longitude, and the difference of longitude into departure, when the ship's course is oblique to

MIDDLE RAIL.

the meridian. It is founded on this principle, which, however, is only approximately true in any case, and not even approximately in high latitudes, when there is also considerable difference between the latitudes left and arrived at; namely, that the departure may be accounted an arc of a parallel of latitude midway between the two extreme latitudes. Hence this rule:—

$$\cos \text{mid. lat.} = \frac{\text{departure}}{\text{diff. long.}}$$

(*Jeans' Navigation*, part ii.)

Middle Rail. In Architecture, the rail of a door level with the hand, on which the lock is generally fixed.

Middle Term of a Categorical Syllogism. In Logic, that term with which the two extremes of the conclusion are separately compared. [SYLLOGISM.]

Middletomite. A fossil resin found at the Middleton collieries near Leeds.

Midshipman. In the Navy, the step next above naval cadet. At nineteen years of age, if he have served five years, the midshipman passes an examination in seamanship, and another in navigation, when he becomes eligible for a lieutenant's commission, although he usually has to serve for some time as sub-lieutenant before obtaining it.

Midships. The middle of the ship, with reference to length or breadth. It is more commonly written *amidships*.

Miemite. A variety of Rhomb Spar of a green colour, from Miemo, in Tuscany.

Miesite. A brown variety of Pyromorphite, from Mies in Bohemia.

Mignonette (Fr.). A favourite garden flower, belonging to the same family as the Weld, and known in science under the name of *Reseda odorata*.

Migration (Lat. migratio). This word is used in Zoology to signify the transit of a species of animals from one locality or latitude to another. The passage is usually to and fro between a temperate and a cold climate, or a temperate and a warm climate; and this periodical change of abode is most general in the arctic species of animals, and least prevalent in the tropical species. The most remarkable, rapid, and extensive migrations are performed by birds, owing to their ability to maintain a long and rapid flight through a medium which offers the least opposition to their progress. The inequalities and alternations of land and water upon the surface of the earth, and the presence of enemies and other dangers, would appear to form insurmountable obstacles to any general or extensive migration of quadrupeds; yet the musk-ox, the rein-deer, the arctic fox, &c., are driven southward by the rigours of the polar winter, and return to the extreme latitudes in the summer season. Less regular, but not less general migrations, take place among the quadrupeds which range the tropical continents in seasons of unusual drought. Vast herds of oxen, goaded by thirst, are thus impelled over the South American Pampas in quest of water.

MILDEW

The valleys of the warmer parts of Africa are occasionally traversed by hosts of quadrupeds, migrating under the same stimulus. Lions and other carnivora have on these occasions been seen absolutely hemmed in by antelopes, gnus, and other herbivorous species which constitute their prey. The Scandinavian LEMMING, however, is the species of quadruped most remarkable for its migration. But the migratory periods are not regular; nor are the immense bodies that travel in a given direction ever known to return. In this respect their migration resembles rather that of the locusts among insects than the true and regular migration of birds, which appears to be influenced mainly by the necessity of providing sufficient food for their young, and by the temporary continuance of such food in the climates best suited for propagation.

The arctic and northern seas, which teem with life during the long unbroken day that constitutes the summer season of such latitudes, are resorted to by numerous aquatic birds during the breeding season; and these birds regularly migrate southward when the severities of winter set in. In temperate latitudes, as those of England, certain spring and summer months are peculiarly favourable to the production of insects in their different stages; and our island is accordingly frequented by many insectivorous birds, which leave warmer latitudes during these months to breed and rear their young with us. As a general rule, it may be stated that birds migrate southward in the northern hemisphere for food principally; but that they migrate northward both to feed and breed. The most remarkable summer immigrants that visit England from the south, and breed in this island, are the swifts, swallows, cuckoo, nightingale, and many other insectivorous Passerine birds; and it is remarkable that the males of the song birds always precede the other sex in their vernal flight.

Mikado. [TRCOON.]

Mildew (in Ger. mehlthau, *rust on corn*). This term is generally applied to a particular mouldy appearance on the leaves of plants, produced by innumerable minute fungi, which, if not checked in their growth, occasion the decay and death of the parts on which they grow, and sometimes of the entire plant. It is common on wheat, and on the hop; and in gardens on the leaves of the peach, the nectarine, and other fruit trees. The causes favourable to the production of mildew are a rich soil and a moist atmosphere, without a free circulation of air or sunshine; or sometimes an excessive dryness, which checks the action of the natural functions of the vegetable organs. In agriculture, this parasitical disease is generally considered irremediable; but in gardening, it may be checked by the application of sulphur in the form of powder to the leaves covered by the fungi, this being found to destroy them without greatly injuring the leaf.

MILE

(Lat. mille passuum, *a thousand paces*). The Roman pace being 5 feet, and a Roman foot being equal to 11·62 modern English inches, it follows that the ancient Roman mile was equivalent to 1,614 English yards, or very nearly 11·12ths of an English statute mile.

The English statute mile was defined (incidentally, it would seem) by an Act passed in the 35th year of the reign of Queen Elizabeth, by which persons were forbidden to build within three *miles* of London; and the mile was declared to be 8 furlongs of 40 perches of 16½ feet each. The statute mile is, therefore, 1,760 yards, or 5,280 feet. [MEASURES.]

The mile is used as an itinerary measure in almost all countries of Europe, particularly those which were formerly under the sway of the Romans; but it is very difficult to conjecture the causes which have given rise to great diversity of its values. It has been supposed that in some countries the Roman mile was confounded with the ancient Celtic league.

The following table, given on the authority of Kelly's *Cambist*, shows the length of the modern mile, and also the league, of various countries, and their relation to the English statute mile:—

	Yards	Stat. miles
Modern Roman mile	1,628	·925
English statute mile	1,760	1·000
Tuscan mile	1,808	1·027
Ancient Scottish mile	1,984	1·127
Irish mile	2,240	1·273
French posting league	4,263	2·422
Spanish judicial league	4,635	2·634
Portugal league	6,760	3·841
German short mile	6,859	3·897
Flanders league	6,864	3·900
Spanish common league	7,416	4·214
Prussian mile	8,237	4·680
Danish mile	8,244	4·684
Dantzic mile	8,475	4·815
Hungarian mile	9,113	5·178
Swiss mile	9,153	5·201
German long mile	10,126	5·753
Hanoverian mile	11,559	6·568
Swedish mile	11,700	6·648

According to the same authority, the Arabian mile is 2,148 yards, the Persian parasang 6,086 yards, the Russian verst 1,167 yards, and the Turkish berri 1,826 yards. The English geographical mile is 1·60th of a degree of latitude, or about 2,025 yards; the geographical league of England and France is 3 such miles, or 6,075 yards; and the German geographical mile is equal to 4 English geographical miles, or 8,100 yards. See a disquisition on the history of the English mile in the *English Cyclopædia*.

Millefoil. One of the English names of the Yarrow, *Achillea Millefolium*, a bitter native herb, whose leaves have been used medicinally.

Miliaria (Lat. from milium, *millet seed*). A disease attended by an eruption resembling millet seed. *Miliary fever*.

MILK

Miliola. The generic name applied by Lamarck to an extinct mollusc, or zoophyte, which has left its small foraminiferous multi-locular shell in great numbers in the strata of many quarries in the neighbourhood of Paris.

Military Train. A regiment organised after the Crimean war, for the purpose of performing the transport duties of the army on a campaign. Its total strength of all ranks for 1865 is upwards of 1,800. The regiment ranks before the foot guards, and immediately after the royal engineers.

Militia (Lat. *military service*). A body of citizens regularly enrolled, and trained to the exercises of war; but in this kingdom not liable to serve out of the limits of Great Britain and Ireland, except by the voluntary act of any particular regiment. The militia is now placed under the lords-lieutenant of counties, appointed by the sovereign, who have power to call them out and train them annually. It is subject to the provisions of the Mutiny Act and Articles of War. When called into active service, the officers rank with those of the regular army, but as juniors of each grade. All persons not labouring under bodily infirmity, or specially excepted, are liable to be chosen for private militiamen, by ballot, in each parish, and are compelled under a penalty of 10*l*. to serve either personally or by substitute. Volunteers paid by consent of the inhabitants, by parish assessments, may, however, be substituted for balloted men. The militia is trained and exercised by battalions or regiments twice in a year, for fourteen days at a time, or once in a year for twenty-eight days, as the lords-lieutenant may decide.

The national guard may be said now to constitute the militia of France. [GUARD, NATIONAL.] In Austria and Prussia it is called *landwehr*; and in the latter country receives full pay during a certain part of every year when it is in exercise. Many unsuccessful efforts were made by German sovereigns, during the wars of the last century, to organise bodies of troops which should be as cheaply raised as militia, and yet be serviceable in foreign war. Frederick the Great used such troops for garrison service. In Prussia every man who has served his three years, or a single year in certain cases, of lawful service in the standing army, belongs to the first class of the *landwehr* until his thirtieth year; and from that time until his fortieth to the second class.

Milk (Ger. *milch*, Lat. *mulgere*, Gr. *ἀμέλγειν*, *to milk*). This important fluid, which is secreted by appropriate glands in the breasts of the Mammalia, constitutes the entire food of the young animal for many months after birth. Its composition, therefore, is of great interest in a physiological and chemical point of view, inasmuch as it must contain within itself all those ultimate and proximate constituents which are required for the support of life and the growth of the body, both in respect to the

MILK

herbivorous and carnivorous tribes. We may, therefore, take *cow's milk* as the type of this secretion; for although the relative proportions of the constituents may vary in other animals, and indeed in the same animal under different conditions of health and diet, their leading characters are retained throughout. The composition and sources of these proximate elements are stated under their respective heads, so that it will only be necessary here to refer to their relative proportions as existing in milk, and to the manner in which they affect its general properties.

The specific gravity of milk varies from 1·018 to 1·045; its density being diminished in proportion to the quantity of butter, and increasing in proportion to the casein. In its healthy state, milk is almost neutral, especially under the influence of mixed food; but it has been observed, that in herbivorous animals it is sometimes slightly alkaline, and slightly acid in the carnivora. Its average composition may be inferred from the following table:—

Water	873·00
Casein	48·62
Sugar	43·90
Butter	30·00
Phosphate of lime	2·31
Phosphate of magnesia	0·42
Phosphate of iron	0·07
Chloride of potassium	1·44
Chloride of sodium	0·24
	1000·00

The yellowish translucency of milk depends upon its butyaceous particles. When examined under the microscope, it presents the appearance of transparent globules floating in a transparent fluid; and the globules seem to consist of butter contained in a very thin investing membrane, which may be broken mechanically, as in the act of churning, or dissolved by adding a few drops of a solution of caustic potash to the milk, which in either case sets the oil free. When allowed to remain for some hours at rest, these globules collect upon the surface, in the well-known form of *cream*. [**BUTTER; CREAM.**] But in addition to the butter thus suspended in or diffused through the milk, it holds two important principles in aqueous solution; namely, milk-sugar, and curd or casein: the former, like butter, a well-defined non-azotised substance [**LACTINE**]; the latter an azotised principle, of the albuminoid type [**CASEIN; CHEESE**], and entirely replacing the albumen (or *lacto-protein*?) which is contained in the so-called colostrum, or the milk first formed immediately after the birth of the young animal. In reference to the saline constituents of milk, it may be observed, that in addition to the phosphates, which are essential to the formation of bone, there are the chlorides of potassium and sodium, and a trace of oxide of iron. Some notion of the variable composition of the milk of different animals may be formed from the following statement given by Regnault:—

MILLEPORES

	Cow	Ass	Goat	Hare	Hog
Water	87·4	90·6	82·0	89·6	88·6
Oil of butter	4·0	1·4	4·6	trace	2·6
Lactine and soluble salts	5·0	6·4	4·6	8·7	4·9
Casein, albumen, and fixed salts	3·6	1·7	9·0	1·7	3·9
	100·0	100·0	100·0	100·0	100·0

The spontaneous souring of milk and the action of the gastric juice upon it have been elsewhere noticed. For the details of its physiological and chemical history, we must refer to other authorities, more especially to Pélouze and Frémy (*Traité de Chimie Organique* iii. 616), and Watts's *Dictionary*, art. 'Milk.'

Milk Fever. [**PURFURAL FEVER.**]

Milk Quartz. A variety of Quartz of a milk white colour, chiefly occurring in Greenland.

Milk Vessels. In Plants, the anastomosing tubes lying in the bark, or near the surface of plants, in which a white turbid fluid is secreted.

Milk-tree. A term sometimes applied to certain trees, whose trunks yield a milky fluid when wounded. The name is applied more particularly to those species in which the fluid is harmless and fit for food—an uncommon circumstance among lactescent plants, whose secretions are generally dangerous. In the Caraccas there is one sort, the *Palo de Vaca*, or Cow-tree of Humboldt, whose milk is a common article of diet among the natives; this is the *Brosimum Galactodendron*, formerly called *Galactodendron utile*, one of the *Artocarpaceæ*. The Kiriaguma of Ceylon, *Gynanema laotiferum*, is another milk-tree; its milk is pleasant to the taste, and used for domestic purposes. In the Canaries, the Tabayba dolce, *Euphorbia balsamifera*, yields a juice which is similar to sweet milk, and when thickened into jelly is eaten as a delicacy, though the *Euphorbias* are generally an acrid poisonous race.

Milk-weed. In Botany, the common name for the genus *Aclepias*.

Milkwort. The common name applied to *Polygala vulgaris*, a native plant, possessing bitter qualities.

Milky Way or Via Lactea. [**GALAXY.**]

Mill Board. A paper employed to make the joints of some kinds of pipes. The mill board is cut to the size of the pipe, and then smeared over with white lead, and pressed up to its work by means of bolts. In order to make it resist the action of moist heat, the mill board is sometimes baked in boiled oil, and again covered with this oil laid on with a brush before being applied.

Millennium (Lat. mille anni, a thousand years). The reign of Christ with His saints upon earth for the space of a thousand years; an idea derived from a passage in the Apocalypse, and not uncommonly entertained by Christians in all ages. It was maintained by Justin Martyr, Irenæus, Tertullian, and others, and refuted by Origen. (Gibbon, ch. xv.; Bertholdt, *Christologia Judeorum*; Eisenmenger, *Das Entdeckte Judenthum*.)

Millepores (Lat. mille, a thousand; porus, a pore). A tribe of Lithophytous Polyptea,

MILLERITE

including those in which the calcareous axis is perforated by extremely numerous pores.

Millerite. Native sulphide of nickel. It occurs in delicate capillary crystals of a brass- or bronze-yellow colour, with a grey or iridescent tarnish in nodules of clay iron-stones in the coal measures of Glamorganshire and elsewhere. Named after Professor W. H. Miller of Cambridge.

Millet (Lat. *milium*, Fr. *millet*). The name given to various grain-bearing grasses, some of which attain a height of from sixteen to twenty feet in favourable situations. The principal Millets are *Panicum miliaceum*, *Setaria italica*, and *Sorghum vulgare*. They are cultivated as grain, and sometimes employed as a substitute for rice or sago by the poorer classes, but more frequently used for feeding chickens and domestic animals. Millet is cultivated to a considerable extent in France, Switzerland, and Southern Germany, but most extensively in Egypt, Syria, Nubia, China, and Hindustan. The climate of England is not sufficiently dry and warm to allow of its cultivation.

Million. A thousand thousand. [NUMERATION.]

Millepedes (Lat. *millepeda*, with a thousand feet). Several insects formerly used in medicine were included under this name: amongst them the *Armadillo vulgaris*, or *pill millepede*; the *Porcellio scaber*, or *Scoter* of the Scotch; the *Oniscus Asellus*, or common *Woodlouse*.

Millstone Grit. A coarse grit stone or conglomerate, more or less compact, belonging to the upper or newer part of the great carboniferous system, and immediately underlying the coal measures in the principal coal districts. Occasionally coal is found regularly bedded with the gritstone, but the seams are poor and thin. The millstone grit is for the most part a local accumulation from 150 to 180 yards thick, and it is widely spread in the northern counties of England and Wales, its outcrop being traced with great regularity. It yields much excellent building material, and is readily distinguished from the coal grits. Many parts of it consist of quartzose conglomerates, more or less coarse in texture.

Lead veins occur in millstone grit in Derbyshire and Yorkshire, but they are more productive in the limestones below. Excellent millstones have been obtained from it, and good firestone for the hearths of iron furnaces. The upper beds are thin, and are used for paving stones, and occasionally for roofing.

There is no exact foreign representation of this division of the carboniferous system.

Miloschine. A chromiferous clay found in soft amorphous masses of an indigo-blue or greenish colour at Rudniak in Servia. Named after Prince Milosch Obrenowitch.

Milvines. A family of Raptorial birds, of which the kite (*Milvus*) is the type. [KITE.]

Mime (Lat. *mimus*; Gr. *μῖμος*, an imitator). The name given by the Greeks to a species of dramatic entertainment, and to the actors by whom it was performed. It consisted

MINA

chiefly of a rude representation of common life, and resembled the modern farce or vaudeville in its character and accompaniments. Sophron of Syracuse, who lived about 400 years before the Christian era, is considered to have brought this species of composition to perfection. (The *Museum Criticum*, No. 7, contains several fragments of mimes by Sophron.) At what period it was first practised at Rome cannot be precisely ascertained; but in the time of the emperors, and even under Augustus, this species of entertainment had attained a high degree of popularity. Among the Romans it was of a still more farical character than among the Greeks, and bordered more upon such mountebank representations as *Punch and Judy* among ourselves, and the *Pantocchini* of the Italians. Mimes originally formed a part of the usual theatrical exhibitions; but they were soon introduced by the wealthy Romans into their private entertainments to divert their guests. At Rome they also held a prominent place at funerals, on which occasions they gave a burlesque representation of the life of the deceased. Thus, Suetonius tells us that the archmiser Favo was present at the funeral of Vespasian: 'Sedet in funere Favo archimimus, personam ejus ferens, imitansque, ut mos est, facta et dicta vivi.'

Mimetite (Gr. *μυμητις*, an imitator; from its resemblance to Pyromorphite). A native arseniate of lead mixed with chloride and phosphate of lead. It was formerly worked as an ore of lead at Drygill in Cumberland, and was used in the manufacture of flint glass, to which it imparted peculiar brilliancy.

Mimosa. A very extensive genus of *Leguminosæ*, chiefly remarkable as containing some of the plants known as *Sensitive Plants*, in which what is called vegetable irritability is very fully displayed. The species called *M. pudica* and *M. sensitiva*, both common in hothouses, afford striking illustrations of this curious peculiarity.

Mimotannic Acid. The astringent acid of catechu, called also *catechu-tannic acid*.

Mimus (Lat. *a mimic*). A genus of Passerine birds, separated by Boié from the thrushes (*Turdus* of Linnæus) on account of the more elongated form of the body, and particularly of the tail, the shorter wings, and more curved upper mandible. The type of this genus is the celebrated *Mocking Bird*.

Mimusops (Gr. *μῖμος*, a mimic; *ὄψ*, the face). This genus of *Sapotaceæ* includes several species which yield hard durable heavy timber. Among these are *M. hexandra* in Peninsular India, and *M. Elengi* and *M. indica* in Ceylon, where the wood is used for house-building. The fruits of *M. Elengi* are eaten, its seeds afford abundance of oil, and a perfume is distilled from its flowers.

Mina (Gr. *μνᾶ*). A weight and coin in use among the Greeks; it varied in different states. The Attic mina, which is most frequently mentioned, was heavier than the Roman pound by about four drachms. Each mina contained 100

MINARET

drachms, and was itself contained 60 times in an Attic talent. The coin was worth a little more than 3*l.* of our money.

Minaret (Arab. *menarah*, a *lantern*). A slender and lofty turret in the mosques of Mohammedan countries, used for the purpose of summoning the people to prayers, and consequently answering the purpose of the belfry in Christian churches. They are usually surrounded with projecting balconies, and are crowned with spires surmounted by a crescent.

Mindererus' Spirit. Solution of acetate of ammonia, first recommended as a febrifuge by Raymond Mindererus, a physician of Augsburg.

Mines and Minerals, Law of. By the law of England all minerals are part of the freehold of the soil under which they are found, with the exception of gold and silver, which are said to belong to the crown. But, by 1 Wm. & Mary c. 50, no mine of copper or lead is adjudged a royal mine, though silver be extracted. Trustees are not now justified, without special authority, in selling mines apart from the surface, without the sanction of the Court of Chancery (stat. 25 & 26 Vict. c. 108, which confirmed previous sales). Lessees, tenants for life, and other partial owners of land cannot lawfully dig mines unless exempted from liability for waste. Mines are not rateable to the relief of the poor, with the exception of coal mines; the latter being expressed in the statute of Eliz., the former are held to be excluded by implication. But quarries are rateable; and the distinction between a mine and a quarry is taken to be, not the nature of the mineral extracted, but the mode of working: thus, a mine of limestone worked by a shaft is not rateable. The law of mines and minerals is subject to a variety of local customs, of which those of Devon and Cornwall are the most remarkable. [STANFORDS.]

According to the law of France and most continental countries, ownership of the soil does not carry with it absolute ownership of mines, and these may be made the subject of *concession* by government to others than the owner, paying the latter a stipulated retribution.

Mines, Military. Excavations made in the rampart of a fortress, or underground, to contain gunpowder or gun cotton, which being exploded forms a breach in the rampart, or destroys any of the enemy's troops or works in its vicinity. Mines are *offensive*, in which case they are constructed by the besiegers of a fortified place; or *defensive*, in which case they are called *counter-mines*, and are executed by the besieged. The cavity for the powder is called a *chamber*, the approach to this a *gallery*, or in very small mines, a *branch*. The systems of mines and counter-mines are fully explained in the article 'Mining' in the *Aide Mémoire to the Military Sciences*, and briefly in Knight's *English Cyclopædia*.

Mineral Adipocere. *Mineral tallow, Hatchettin.* A greasy bitumen, found in the argillaceous ores of iron.

MINERAL VEINS

Mineral Caoutchouc. The elastic bitumen found at Castleton in Derbyshire.

Mineral Carbon or Mineral Charcoal. Names given to the thin fibrous layers of nearly pure carbon of a silky-black colour which occur in the coal measures of Whitehaven and elsewhere. By the miners it is called *mother of coal*.

Mineral Chameleon. A manganate of potash, obtained by fusing a mixture of nitre, or chlorate of potash, and black oxide of manganese. So called from the variety of colours which its hot aqueous solution successively exhibits. [MANGANES.]

Mineral Green. Carbonate of copper, obtained by precipitating a hot solution of sulphate of copper by carbonate of soda.

Mineral Oil. [OILS.]

Mineral Pitch. [ASPHALT; BITUMEN.]

Mineral Veins. Fissures and crevices occur in all rocks, and are in many cases filled up with crystalline material, either segregated from the enclosing rock or brought in from a distance. Such fissures are called *mineral veins*. They are almost always more or less systematic, being found in sets parallel or at right angles to each other, or making some definite angle with the axis of elevation. When such mineral veins occur on a large scale in rocks that have been metamorphosed, and in districts where granite, micaceous schists, crystalline limestone, slate, and other altered rocks abound, they assume an important character, and are often found to contain in some sets of veins either native metals, or the oxides, carbonates, chlorides, or sulphurets of metals, which appear to be present according to the action of some great law not yet clearly understood, but having reference to the history of the rock during or subsequent to its metamorphosis. Such veins are called *lodes*, or metalliferous veins. [LODES.]

Veins are generally limited in length and breadth, but the limits cannot be easily traced, as the vein often dies away and reappears. In depth it is not easy to say how far they are limited, though in this respect also there seems to be a practical barrier, and a check to their productive power, if we may accept the general results of experience in deep mines. This conclusion, however, must be accepted with many reservations and much caution.

Veins are of various kinds: 1. Simple crevices, *rake veins*, filled with ore and earthy minerals, crossing all the rocks indefinitely, and being, in fact, mere cracks of the earth's surface. Such cracks in South America have been followed for fifty miles. They are often accompanied by other cracks parallel to them or nearly so, but with which they have no connection. They are often, but not always, wider at the surface than in the depth.

2. *Slip veins*, or veins accompanying a fault. These are often more complicated, as connected with mechanical disturbances and disruption of the rock. Such veins often diverge into strings, and the metallic produce is di-

MINERAL VEINS

minished. They are generally in systems, and crossed by other veins. They are often much less vertical than the simple crevices. Such veins do not always traverse the strata indefinitely; and when they do, the state of the vein depends much on the nature of the stratum in which it occurs.

3. *Pipe veins* are irregular cavities opening into each other, and running down into the earth, often connected with disturbances and faults, but not necessarily continuous with them. Pipe veins usually cross the stratification.

4. *Flat veins* are spaces between beds containing ore. These often expand into large spaces resembling pipe veins, but differ from them by having a manifest reference to the bedding.

The veins above described chiefly affect stratified rocks; but in granite, porphyry, and all varieties of slate and schist, there are others on a larger scale and systematically arranged.

There is no special order of metals in mineral veins, although in every mining district there is a certain amount of uniformity in this respect. Thus in Cornwall the tin veins, copper veins, and lead veins rarely interfere one with another, and the important veins are pretty clearly defined. Iron is very generally found mixed with silica near the top or outcrop of a vein, forming what is called a *rossan*; and gold is also common in such positions. Copper occurs in sandy and schistose districts next in order of depth, copper pyrites mixed with iron pyrites, decomposed and converted into carbonate, showing itself near the surface. Tin generally accompanies granite, and appears in granitic veins. Silver when unmixed with lead is also found in granite. Lead and zinc, the former often with much silver, occur

MINERAL WATERS

combined with sulphur in limestones; the latter, either carbonate or sulphuret, also in limestones. Few valuable minerals are found in sandstone, though there are not wanting important exceptions.

Mineral veins crop out at the surface, and are generally known by a metalliferous appearance, often very slight, in the quartz of which they are formed. They are also sought for by mining operations. Their contents are rarely uniform, nor is the law of their formation or filling clearly understood. It is probably connected with the passage and circulation of magnetic currents through the earth's crust, and everything leads to the conclusion that the filling is an operation constantly and incessantly going on in all parts of the earth. The selection of material, no doubt, depends on the action of laws perfectly intelligible, and these we may expect some day to discover. At present they are very obscurely guessed at even by the most intelligent.

Mineral Waters. This term is applied to certain spring waters containing so large a proportion of foreign matter as to be unfit for ordinary use.

Mineral waters may, in most cases, be artificially prepared by the skilful application of the knowledge derived from analyses, with such precision as to imitate very closely the native springs. When the various earthy or metallic constituents are held in solution by carbonic acid, they should be placed along with their due proportions of water in the receiver of the aerating machine, and then the proper quantity of gas should be injected into the water. Sufficient agitation will be given by the action of the forcing-pump to promote their solution. (*Ure's Dict. of Arts, &c.*)

The following table shows the composition of several of the principal mineral springs of Europe:—

*Tabular View of the Composition of the Principal Mineral Waters of England.
One Pint (Wine Measure) contains the following Ingredients:—*

Mineral Yellow or Patent Yellow. A compound of oxide and chloride of lead, obtained by digesting powdered litharge in a solution of common salt, washing, drying, and fusing the product.

Mineralisers. The substances with which metals are combined in their ores. Thus, in the native oxides, oxygen is called the mineraliser; sulphur is also a very common mineraliser, as in copper pyrites, galena, &c.

Mineralogy. This name is given to the science which teaches us to distinguish mineral bodies from each other, and makes us acquainted with their mode of occurrence in the earth, the manner in which they have been formed, the changes which they have undergone since their formation, their composition, properties, relations, and uses; and, also, the mode of describing and arranging them.

It comprises, therefore, all inorganic natural objects, or all those substances found in or on the earth which exist by virtue of chemical and cohesive forces, in contradistinction to substances belonging to the animal and vegetable kingdoms, which are possessed of a vitality upon which their existence depends. This being

the case, it follows necessarily that the science of mineralogy includes the liquids and gases which occur naturally on the surface or in the interior of the earth—because, although the term *mineral* may not be strictly applicable to them, they are not the less natural substances which cannot be comprised amongst those which are formed by the aid of vital forces.

The study of mineralogy, should, therefore, precede, and to a certain extent form the groundwork of the science of geology, since it treats of and describes the individual qualities of the simple minerals which enter into the composition of the materials forming the earth's crust; while geology treats of them as they are associated in the structure of the earth, of which they form the rocks and soils.

'There is no branch of science,' says Sir J. Herschel, 'which presents so many points of contact with other departments of physical research, and serves as the connecting link between so many distant points of philosophical speculation, as this. To the geologist, the chemist, the optician, the crystallographer, it offers especially the very elements of their

MINERALOGY

knowledge, and a field for many of their most curious and important enquiries; nor, with the exception of chemistry, is there any which has undergone more revolutions, or been exhibited in a greater variety of forms. To the ancients it could scarcely be said to be at all known; and, up to a comparatively recent period, nothing could be more imperfect than its descriptions, or more inartificial and unnatural than its classifications. The more important minerals in the arts, indeed—those used for economical purposes, and those from which metals were extracted—had a certain degree of attention paid to them for the sake of their utility and commercial value, and the precious stones for that of ornament; but until their *crystalline forms* were attentively observed, and shown to be determinate characters, on which dependence could be placed, no mineralogist could give any correct account of the real distinction between one mineral and another. It was only, however, when chemical analysis had acquired a certain degree of precision and universal applicability, that the importance of mineralogy as a science began to be recognised, and the connection between the external characters of a stone and its ingredient constituents brought into distinct notice.

Mineralogy is chiefly based upon a study of the external and physical characters of minerals, and upon a knowledge of their chemical composition—the characters of a mineral including everything which can be the subject of an observation by means of which it can be recognised or identified.

But even this knowledge is insufficient to

afford a complete mastery of the subject, which must be founded on a knowledge of crystalline form and structure [CRYSTALLOGRAPHY] as well as of chemical composition. Hence the subject may be considered under the heads of Physical Characters, Crystallographic Characters, and Chemical Composition.

The general characters of minerals may be considered under the following heads: 1. Those depending on light, as Colour, Transparency, Lustre, or on optical properties, as Refraction, Polarisation, &c. 2. Those dependent on physical properties, as Specific Gravity, Phosphorescence, Fluorescence, Electricity, Magnetism. 3. Those dependent on cohesion, as Frangibility or Tenacity, Hardness, Toughness, Fracture, &c., and on various other properties, as Stain, Streak, Taste, Odour, Feel, Adhesion to the tongue, &c.

With regard to the classification of minerals, although it is fully agreed that a knowledge of chemical composition must form the basis of a perfect system of classification, it is found in practice that an arrangement founded solely on chemistry is attended with much inconvenience, and that for practical purposes an artificial system will prove to be more useful.

The most generally useful system of classification for all working purposes is that given below, and extracted from the Introduction to Bristow's *Glossary of Mineralogy*. Such a mode of arrangement may be adopted with advantage, both for its simplicity as well as its practical utility, being based on chemical composition with such modifications only as may be considered likely to increase its usefulness.

NON-METALLIC MINERALS.

CLASS I.

CARBON AND BORON.

CARBON *and its Natural Compounds.*

Diamond
Boort.

Graphite.
Tremseheerite.

Coals.
Non-bituminous Coal.
Anthracite, or Stone Coal.

Bituminous Coal.
Common Coal.
Albert Coal, or Albertite.
Cannel Coal.
Horn Coal. }
Torbanite. }

Brown Coal.
Lignite.
Jet.
Burturbrand.
Dysodile.

Mineral Oils and Resins.
Naphtha.

Petroleum.
Bitumen.
Elaterite, or Elastic Bitumen.
Asphalt.

Amber.
Copaline.
Highgate Resin.

Scleretinite.
Retinite.
Piauzite.
Walchowite.
Krantzite.
Berengelite.
Middletonite.
Anthracoene.
Pyropissite.
Phylloretine.
Ozokerite.
Hatchettine.
Idrialine.
Tekoretine.
Scheererite.
Könlite.
Köselinite
Baikerite.

Fichtelite.
Guyaquillite.
Hartite.
Hartine.
Ixolite.
Bog Butter.
Bathvillite.

Inflammable Salts.

Dinite.
Dopplerite.
Mellite.

BORON.

Sassolin, or Boracic Acid.
Larderellite, or Borate of Ammonia.
Borax, or Borate of Soda.
Hayesine, or Borate of Lime.
Rhodisite.

Borate of Lime and Soda.
Cryptomorphite.
Tinkalite.

Boracite, or Borate of Magnesia.
Stamfurtherite.
M M 2

MINERALOGY

Scaibelite.

Hydroboracite.

Lagonite.

Warwickite.

CLASS II.

SULPHUR AND SELENIUM.

SULPHUR.

Native Sulphur.

Selen-Sulphur.

SELENIUM.

Clausthalite.

Selenbleikupfer.
Selenkohaltblei, or Tilkero-
dite.

Onofrite.

Lehrbachite.

Berzelianite.

Naumannite.

Selenkupferblei.

Eukairite.

CLASS III.

HALOIDS AND SALTS.

AMMONIA.

Ammonia-Alum.

Tschermigite.

Bicarbonate of Ammonia.

Mascagnine or Sulphate of
Ammonia.

Sal Ammoniac or Muriate
of Ammonia.

POTASH.

Nitre, or Nitrate of Potash.

Glaserite, or Sulphate of
Potash.

Misenite.

Sylvine, or Muriate of
Potash.

Jarosite.

Polyhalite.

SODA.

Trona, or Carbonate of
Soda.

Urac.

Natrolite.

Thermonatrite.

Thenardite.

Glauber Salt (Sulphate of
Soda).

Exantholose.

Lecontite.

Glauberite.

Nitrate of Soda, or Nitra-
tine.

Loweite.

Common or Rock Salt.

Martinite.

Reussite.

Stercorite.

BARYTA.

Witherite.

Baryto-calcite.

Barytes.

Bolognese Stone.

Hepatite.

Allomorphite.

Cawk.

STRONTIA.

Strontianite.

Emmonite.

Barystrontianite.

Celestine.

LIME.

Calc Spar, or Calcite.

Iceland Spar.

Madrepore.

Stalactite.

Stalagmite.

Oriental Alabaster.

Onyx Marble.

Eye Stone.

Travertine.

Ostreocolla.

Calcareous Tufa.

Kunkur.

Marble.

Lumachello, or Fire

Marble.

Cotham, Ruin, or Land-
scape Marble.

Stinkstone, or Swinestone.

Agaric Mineral.

Aphrite.

Fontainebleau Sandstone.

Natro-calcite.

Plumbo-calcite.

Strontiano-calcite.

Conistonite.

Whewellite.

Aragonite.

Mossotite.

Floa-ferri.

Satin Spar.

Sprudelstone.

Tarnowitzite.

Dolomite.

Oonite.

Brossite.

Rauchkalk.

Pearl Spar.

Bitter Spar, or Rhomb Spar.

Miemite.

Predazite.

Brown Spar.

Ankerite.

Fennite.

Gurhoite.

Apatite.

Asparagus Stone.

Lazurapatite.

Moroxite.

Phosphorite.

Francoilite.

Odontolite.

Osteolite.

Talc-Apatite.

Herderite.

Sombrecite.

Brushite.

Anhydrite.

Muriacite.

Tripe Stone.

Vulpinite.

Selenite.

Alabaster.

Gypsum.

Satin Spar.

Schaumkalk.

Dreelite.

Polyhalite.

Datholite.

Nitro-calcite.

Gay-Lussite.

Haidingerite.

Kühnite.

Romaine.

Scheelite.

Perowskite.

Rutherfordite.

Azorite.

Fluor Spar.

Blue John.

Antozonite, or Fetid Fluor.

MAGNESIA.

Magnesite.

Globerite.

Nitro-Magnesite.

Magnesia-Alum.

Epsomite.

Kieserite.

Brunnerite.

Tachydrite.

Struvite.

Wagnerite.

Hoernesite.

ALUMI

Diaspore.

Hydrargyllite.

Gibbsite.

Bauxite.

Alunogene.

Kapnicite.

Keramohalite.

Websterite.

Hallite.

Paraluminite.

Potash Alum.

Alunite, or Alum-stone.

Loewigite.

Pissophane.

Svanbergite.

Amblygonite.

Wavellite.

Lasionite.

Turquois.

Callais.

Fischerite.

Pegonite.

Lazulite.

MINERALOGY

Childrenite.

Evansite.

YTTRIA.

Phosphate of Yttria, or
Xenotime.

MIRCONIA.

Wöhlerite.

Pyrrhite.

CEBIA.

Fergusonite.

CLASS IV.

EARTHS.

SILICA, ALUMINA, MAG-
NESIA, AND THEIR HY-
DRATES.

SILICA.

*Anhydrous Silica, or
Vitreous Quartz.*

Rock Crystal.

Amethyst.

False Topaz.

Citrine.

Smoky Quartz, or Cairngorm.

Morion.

Rock Crystal with included
capillary crystals of—

Titanium.

Epidote.

Amphibole.

Scales of Mica.

Chlorite.

Bitumen.

Enhydros, or Rock Crystals
Containing Water and other
liquids, also Brewsterline,
Amethystoline, Crypto-
line, &c.

Rose Quartz.

Siderite.

Greasy Quartz.

Fetid Quartz.

Milk Quartz.

Ferruginous Quartz.

Hacked Quartz.

Potato Stone, or Geode.

Fulgurite.

Aventurine.

Prase.

Chalcedonic Quarts.

Chalcedony.

Beekite.

Saphirine.

Haytorite.

Carnelian.

Stygmite.

Sard.

Cat's Eye.

Chrysoprase.

Agate.

Moss

Ribbon Agate.

Circle Agate.

Eye Agate.

Fortification Agate.

Zoned or Banded Agate.

Variegated Agate.

Broccolated Agate.

Leonine.

Mocha Stone.

Agate Jasper.

Plasma.

Onyx.

Sardonyx.

Silicified Wood.

Flint.

Chert.

Hornstone.

Bombite.

Jaspersy Quarts.

Jasper.

Red Jasper.

Yellow Jasper.

Egyptian Pebble.

Striped or Banded Jasper.

Bloodstone, or Heliotrope.

Porcellanite, or Porcelain

Jasper.

Touchstone, Lydian Stone,

or Basanite.

Cellular Quartz, or Float-

stone.

Silicious Sinter.

Pearl Sinter, or Fiorite.

Geyselite.

Tripoli.

Sandstone.

Flexible Sandstone.

Randanite.

Hydrous Silica.

Opal.

Noble or Precious Opal.

Harlequin Opal.

Golden Opal.

Fire Opal.

Common Opal.

Wax Opal.

Mendite.

Semi-opal.

Hyalite, or Müller's Glass.

Hydrophane.

Pyrophane.

Cacholong.

Tabasheer.

Wood Opal.

Michaelite.

Opal Jasper.

Alumocalcite.

ALUMINA.

Corundum.

Sapphire.

Oriental Ruby.

Astaria, or Star Stone.

Star Sapphire.

Star Ruby.

Emery.

Rotten Stone.

Aluminate of Glucina.

Chrysoberyl.

Gymphane.

Alexandrite.

Aluminate of Magnesia.

Völknerite.

Houghtite.

Spinel.

Automollite.

Candite.

Ceylanite.

Dyaluite.

Chlorospinel.

Gahnite.

Heroinite.

Zellanite.

Spinel Ruby.

Balas Ruby.

Rubicelle.

Aluminate of Lime

Prosopite.

*Aluminate of Lime, Magnesia,
and Iron.*

Turnerite.

Aluminate of Zinc and Iron.

Kreittomite.

MAGNESIA.

Periclase, or Native Mag-
nesia.

Brucite, or Hydrate of
Magnesia.

CLASS V.

SILICATES.

SILICATES AND ALUMINATES.

*Hydrous Silicates with Borate
of Lime.*

Datholite.

Botryolite.

Silicates of Lime.

Anhydrous.

Wollastonite, or Tabular
Spar.

Chelmsfordite.

Hydrous.

Plombierite.

Okenite.

Dyscoladite.

Ædelforsite.

*Hydrous Silicates of Lime
and Soda.*

Pectolite.

Soda Table-spar.

Ratholite.

Stallite.

*Hydrous Silicates of Lime
and Potash.*

Apophyllite

Tumelite.

Albin.

Oxhaverite.

MINERALOGY

Anhydrous Silicate of Lime, Soda, and Potash.

Osmelite.

Anhydrous Silicate of Lime and Iron.

Babingtonite.

Iron-lime Garnet.

Black Garnet, or Melanite.

Apome.

Oolophonite.

Pyreneite.

Anhydrous Silicates of Iron and Soda.

Arfvedsonite.

Achmite.

Silicates of Magnesia.

Anhydrous.

Chrysolite, or Peridot.

Monticellite.

Olivine.

Boltonite.

Forsterite.

Hydrous.

Hydrated Olivine, or Vil-
larsite.

Noble Serpentine.

Common Serpentine.

Bowenite.

Williamite.

Verde di Prato.

Verde di Susa.

Bagratiomite.

Fibrous Serpentine.

Baltimorite.

Chrysolite.

Metaxite.

Picrofite.

Foliated Serpentine.

Antigorite.

Marmorite.

Steatite, or Soapstone.

Potstone.

Rensselaerite.

Meerschaut.

Talc.

Neolite.

Deweylite.

Hydrophite.

Schiller Spar.

Aphrodite.

Quincite.

Spadaite.

Asbestos of Koruk.

Kerolite.

Picrosmine.

Anhydrous Silicate of Mag- nesia with Fluoride of Mag- nesium.

Chondrodite.

Anhydrous Silicates of Magnesia and Lime.

Brachite.

Jade, Nephrite, or Axe
Stone.

Pyroxene.

Augite.

Egyrina.

Arfvedsonite.

Hedenbergite.

Polylite.

Green Coccolite.

Funkite.

Diopside.

White Coccolite.

Alalite.

Fassaite.

Sahlite.

Balkalite.

Pyrgom.

Malacolite.

Breislackite.

Acanthoide.

Jeffersonite.

Diallage, or Aluminous

Augite.

Bronzite.

Hypersthene.

Schiller Spar (G. Rose).

Smaragdite.

Uralite.

Pargasite, or Noble Horn-
blende.

Common Hornblende.

Diastalite.

Edenite.

Gamsgradiite.

Tremolite.

Peponite.

Grammatite.

Raphilite.

Anthophyllite.

Gedrite.

White or Oriental Jade.

Calamite.

Glassy Actinolite.

Asbestiform Actinolite.

Rock Wood.

Mountain Cork.

Mountain Leather.

Mountain Paper.

Asbestos.

Amianthus.

Green Diallage.

Carinthine, or Ferruginous

and Aluminous Horn-
blende.

Hydrous Silicates of Mag- nesia and Iron.

Cumingtonite (var. of
Anthophyllite).

Monradite.

Dermatin.

Picrophyll.

Hydrous Silicate of Magne- sia, Lime, and Iron.

Diallasite.

Hydrous Silicate of Soda, Magnesia, and Iron.

Crocidolite.

Hydrous Silicate of Cerous Oxide.

Cererite.

Anhydrous Silicate of Yttria.

Gadolinite.

Anhydrous Silicate of Glu- cina.

Phenakite.

Anhydrous Silicate of Glu- cina and Lime.

Leucophane.

Silicates of Alumina.

Anhydrous.

Staurolite.

Andalusite.

Chlaxolite.

Ryanite.

Rhoxizite.

Bamlite.

Monrolite.

Sillimanite.

Bucholzite.

Fibrolite.

Worthite.

Xenolite.

Talcite, or Nacrite.

Hydrous.

Scarbroite.

Schröterite, or Opal Alle-
phane.

Miloschine.

Allophane.

Porcelain Clays.

Kaolin or China Clay.

Smelite.

Fire-clay.

Pholerite.

Lithomarge, or Rock Mar-
row.

Carnat.

Melopaita.

Myelin.

Halloysite.

Severite.

Smectite.

Lenzinite.

Bole.

Bole of Sinope.

Oohran.

Razoumoffskin.

Salt Clay.

Agalmatolite, or Figure
Stone.

Korette.

Catlinite.

Lardite.

Dysyntrite.

Pyrophyllite.

Collyrite.

Hovite.

Dillnite.

Cimolite.

Tuesite.

Montmorillonite.

MINERALOGY

Lemnian Earth.
Malthacite.
Rock Soap.
Fuller's Earth.

Anhydrous Silicates of Lime and Fluorine.

Topas.
Yellow Topas.
Blue Topas, or Brazilian
Sapphire.
White Topas.
Minas Novas.
Pingué d'eau, or Water
Drop.
Pycnita.
Pyrophyllite.

*Silicates of Alumina with
Silicates of Potash, Soda,
Lithia, Baryta, Strontia,
Magnesia, Protoxide of
Cerium, Yttria, Glucina,
Manganese, and Protoxide
of Iron.*

Anhydrous Silicates of Alumina, Potash, Soda, Lime, &c.

Sodalite.
Lapis Lazuli.
Häuyne.
Noseane.
Leucite.
Nepheline.
Éissolite.
Davyna.
Cancrinite.

FELSPAR SECTION.

Orthoclase, or Potash Fel-
spar.
Adularia.
Moonstone.
Sunstone.
Rhyacolite.
Valencianite.
Amanzite.
Microcline.
Murchisonite.
Necronite.
Weissigite.
Chesterlite.
Amazon Stone.
Glassy Felspar, or Sanidine.
Ice Spar.
Perthite.
Loxoclase.
Erythrite.
Variolite.

Albite, or Soda Felspar.
Pericline.

Oligoclase.
Peristerite.
Hafnæjordite.
Andesine.

Labradorite, or Labrador

Felspar.
Paralogue.
Faulite.
Maulite.
Vogsite.

Fluocerite.

Some of the names in the preceding list have been purposely inserted twice. By that means, certain groups (as the Garnets, Felspars, Zeolites, &c.) can be either kept together, or the minerals which compose them can be inserted in the places which they would more properly occupy, if arranged strictly according to the chemical composition of each particular member.

The names printed in a smaller type are those of varieties of the mineral which they immediately follow.

Minerva. This name of the Latin goddess who was identified with the Greek Athénè is, in the opinion of Professor Max Müller, clearly connected with *mens*, the Greek μένος, and the Sanscrit manas, *mind*, thus expressing a pure intellectual idea; while that of Athénè denotes the physical character of the dawn-goddess, who springs from the forehead of Zeus, *the sky*. It is not, however, difficult to trace the connection of the two ideas. The kindred Sanscrit roots *ah* and *dah* which furnished names for Ahana and Dahana (Daphne), *the dawn*, supplied also the germ of Athénè; and the notion of the being who wakes up the world after the darkness of night soon passed into that of wisdom, the metaphorical connection of light and knowledge (the φῶς and γνῶσις of the fourth Gospel) being of the closest kind. Thus in one of the Vedic hymns it is said of the dawn that 'waking every mortal to walk about, she received praise from every thinker.' It must likewise be remembered that the Latin name Minerva is explained by *manens*, the morning, by *manara*, a verb specially applied to the rising sun, and by *Matuta*, *the dawn*. But while the general characteristics of the goddess are for the most part faithfully preserved, the myths which have clustered round these names vary greatly in form and incident. Thus the Vedas mention no mother of the dawn, and the Homeric poems know of no mother of Athénè, whom they represent throughout as a virgin goddess. As springing

from the forehead of Zeus, *Dyu, the east*, she was called at Rome Capta, i.e. Capita (from caput, *the head*); in Messene, Koryphasia (κορυφή, *the head*); in Argos, Akria (ἀκρος, *topmost*). (Max Müller, *Lectures on Language*, second series, pp. 503 et seq.) But there were legends which made Apollo the son of Athénè, and these are at once explained if we regard him as the sun-god rising from the brightness of the dawn, while as following the night he was the son of Leto (a name which reappears in the words Latona, Lethe, lethum, all denoting forgetfulness and death). In the *Iliad* and *Odyssey*, Athénè is intimately associated with the solar heroes Achilles and Odysseus; it is she who restores the latter to his pristine beauty, and imparts vigour to the failing limbs of Laertes. In general she is represented in these poems as being in perfect accord with the will of Zeus; but in one passage of the *Iliad* (i. 400) she engages in an abortive conspiracy to bind Zeus, in which she is the accomplice of Hera and Poseidon. In the legend of Pandora, at the instigation of Zeus she takes part in the plot which results in the increased wickedness and misery of man; while in contrast with this the myth of Prometheus exhibits her as aiding in his theft of fire against the will of Zeus, and one version represents her as so acting; not from feelings of friendship, but from the passion of love. Her epithet τριτογένηα is explained by M. Béal (*Hercule et Cacus*, p. 17) by a reference to the Vedic Trita, who reigns over the waters and the air, and whose name reappears in the Greek Triton and Amphitrite.

At Rome, Minerva had three temples: one on the Capitol; a second on the Aventine; and a third on the Cælian Mount. There were also two great festivals celebrated annually in her honour; the one called QUINQUAGESIMA or QUINQUATRIA, the other QUINQUATRIA MINORA [which see]. The personification of thought or judgment in the Latin Minerva is shown in many proverbial phrases, as *Sus*

MINIATURE

(the fool instructs the wise); to do a thing, *tenui, pinguì, or crassè Minervè*, is to do it poorly, stupidly, or awkwardly.

Miniature (Fr. from *miniare, to colour with minimum*, first applied to the decoration of MSS., and signifying the large initial letters written in minimum or red lead). In Painting, a representation of nature on a very small scale. *Miniature painting* is generally executed on ivory; and is, as to composition, drawing, and finishing, subject to the same laws as painting. The outline is traced upon the ivory with a silver point or pencil, and must be extremely light and delicate. This is afterwards drawn in with thin carmine as correctly as possible; the corrections being made with finely powdered pumice-stone, rubbed on with a paper or leather stump. The dead colouring then proceeds, wherein the shadows are left delicate and the lights strong, the full effect being afterwards produced by dotting. The artist usually begins the shades with vermilion and carmine, giving the strongest touches to the most prominent parts, and to the parts where separations are marked out in shades that are obscure. Indigo is afterwards used for the bluish shades on such parts as recede from the light. Yellow tints, composed of ochre and vermilion, are usually employed on the sides of the nose towards the bottom, under the eyebrows, underneath the cheeks, and on other parts rising towards the light. The backgrounds, if dark, are commonly composed of bistre, umber, or Cologne earth, with black and white; others of a yellow cast by the use of ochre. The grey backgrounds are formed by black, white, and a little indigo. When of a green or olive hue, Dutch pink, white, and black are the ingredients. The backgrounds are formed in two coats, first laying on a light thin tint, and afterwards a darker one of the same colour, evenly and smooth. The dotting is performed by separate dots, or by short hatching strokes crossing each other every way so as to have the appearance of being dotted.

Among miniature painters, the most distinguished are: Attavante; Memling (died 1496); Giulio Clovio; Nicholas Hilliard; Isaac Oliver and Peter Oliver; Samuel Cooper (1609-72); Jacques Antoine Arlaud (1688-1743); Rosalba Carriera; and Jean Étienne Liotard, who died in 1776: the present century has also had many distinguished artists of this class, but the art of miniature painting as applied to portraiture has greatly suffered of late years through the introduction of photography.

Minim (Lat. *minimus*). In Music, a character η equal in duration to two crotchets, or half a semibreve.

MINIM. The sixtieth part of a fluid drachm.

Minims or Minimi, Order of the. A religious order instituted by St. Francis de Paulo in the fifteenth century. By the name, derived from Lat. *minimus, the least*, the founder meant to indicate that humility

MINIMUM SQUARES

should be the distinguishing feature of the order. In conformity with this design the rules he prescribed were of the strictest kind. Besides the three usual vows of poverty, continence, and obedience, the most rigid abstinence was inculcated. Except in cases of illness, the members were prohibited not only from touching animal food, but even butter, milk, or cheese, or indeed any kind of sustenance in the composition of which such materials were used. Their dress was of the coarsest kind; the colour being black, like that of the Franciscans. Long before the death of its founder, this order had attained so high a degree of celebrity for sanctity that it could boast of monasteries in Italy, France, Spain, and Germany; and at no very distant period it counted no fewer than 460 religious houses scattered throughout Europe and Asia.

Minimum. [MAXIMA and MINIMA.]

Minimum Squares. In the theory of observations the *method of minimum squares* is that by means of which the most correct result is sought to be deduced from a series of mutually discordant, but equally trustworthy, observations. The principles upon which the method is founded are somewhat obscure, and differ in different writers, all of whom, however, agree in their conclusions. The reader will find these principles ably discussed in a memoir by Ellis in the eighth volume of the *Cambridge Transactions*, 1844. We must here confine ourselves to the briefest possible illustration of the method, and refer the reader for principles and details to the collected works of Gauss and Laplace, the founders of the method, or to one or other of their commentators; amongst whom may be mentioned: Poisson (*Connaissance des Temps*, 1827); Ellis; Ivory in *Tilloch's Magazine* and *Philosophical Magazine*; Airy in his *Theory of Errors of Observation*, &c. London 1861; and the 'Essays on Probabilities' in the *Cabinet Cyclopædia* 1838, *Encyclopædia Metropolitana*, and *Penny Cyclopædia*. Gauss' researches on the subject have been collected and translated by Bertrand under the title *Méthode des Moindres Carrés*, Paris 1855—a useful little work.

To illustrate the method by an example, let us suppose our object to be the determination of the most probable values of a series of n magnitudes, x_1, x_2, \dots, x_n , which satisfy a certain equation of condition

$$a_1 x_1 + a_2 x_2 + \dots + a_n x_n - V = 0;$$

of which the coefficients a_1, a_2, \dots, V , however, can only be determined by observations liable to error. By a series of m equally trustworthy observations (m usually exceeds n), we shall be led to the following system of equations:—

$$a_{1,1} x_1 + a_{1,2} x_2 + \dots + a_{1,n} x_n - V_1 = e_1$$

$$a_{2,1} x_1 + a_{2,2} x_2 + \dots + a_{2,n} x_n - V_2 = e_2$$

$$\dots \dots \dots$$

$$a_{m,1} x_1 + a_{m,2} x_2 + \dots + a_{m,n} x_n - V_m = e_m$$

where e_1, e_2, \dots, e_m are unknown quantities which would severally vanish if the observa-

tions were all accurate. This not being the case, they represent the *errors of the observations*. Now by the law of minimum squares the most trustworthy values of $x_1, x_2 \dots x_n$, under the given circumstances, are those which render the sum of the squares of the errors, viz. $e_1^2 + e_2^2 + \dots + e_n^2 = s$, a MINIMUM. According to the principles of the differential calculus, therefore, the n equations, which precisely suffice for the determination of $x_1, x_2 \dots x_n$, are—

$$\frac{1}{2} \frac{ds}{dx_1} = a_{1,1} e_1 + a_{2,1} e_2 + \dots + a_{n,1} e_n = 0$$

$$\frac{1}{2} \frac{ds}{dx_2} = a_{1,2} e_1 + a_{2,2} e_2 + \dots + a_{n,2} e_n = 0$$

$$\frac{1}{2} \frac{ds}{dx_n} = a_{1,n} e_1 + a_{2,n} e_2 + \dots + a_{n,n} e_n = 0.$$

The solution of these equations, after substituting for e_1, e_2 &c. their values in x_1, x_2 &c., is effected in the ordinary manner. Instead of here exhibiting the general formulae, we prefer to consider the special case where there is but one magnitude $x_1 = V$ to be determined directly from observation. We have here, of course, $a_{j,j} = 0$ for all values of j different from 1, and $a_{1,1} = 1$ for all values of i . All the above equations vanish except the first, which reduces to $mx_1 = V_1 + V_2 + \dots + V_n$, and gives us the ordinary *average* or arithmetic mean of all the observations, as the best value of x_1 . Suppose next we had to determine the most probable value of a certain quotient $x_1 = \frac{V}{a_1}$ from n observations which gave the dividends $V_1, V_2 \dots V_n$, and the corresponding divisors $a_{1,1}, a_{2,1}, \dots a_{n,1}$. We should have, from the first, and sole equation,

$$x_1 = \frac{a_{1,1} V_1 + a_{2,1} V_2 + \dots + a_{n,1} V_n}{a_{1,1}^2 + a_{2,1}^2 + \dots + a_{n,1}^2},$$

as the most trustworthy value of the unknown quotient $\frac{V}{a_1}$. The quotient obtained by dividing the mean of the observed dividends V by the mean of the observed divisors a_1 , that is to say the quotient

$$\frac{V_1 + V_2 + \dots + V_n}{a_{1,1} + a_{2,1} + \dots + a_{n,1}}$$

would in general differ from the above and be less trustworthy.

MINING. The operation of discovering and removing from the bowels of the earth such minerals as are valuable to man. When the minerals in question occur at the earth's surface, so that they can be removed by the light of day, the operation is properly regarded as QUARRYING [which see]. The nature of the materials removed should make no difference in the term, as many earthy minerals are mined for, and many mineral veins quarried.

The first operation of mining is the discovery of mineral, and this depends partly on the geological position of the mineral sought for. If a bed or stratum is required to be extracted, and

this bed is nearly horizontal, it will crop out along a line, and levels or tunnels driven in at any part of this line or outcrop will lead to a knowledge of the state of the deposit, and suggest means of working it. If a mineral vein is the object, the outcrop is less distinct, and often at the surface the discovery indicates very slightly the nature and magnitude of the deposit. These two great methods of mining are illustrated in England, one by coal mining, and the other by copper and lead mining.

In coal mining, the object is to remove as much as possible of a distinct bed or deposit of mineral, forming an integral part of the earth at the spot where it occurs. It is clear that if this be removed, the earth above must come down, the mineral having been entirely under the pressure of the superincumbent mass, which increases with the depth of extraction. Provision must, therefore, be made against the falling in of the roof during the progress of extraction. It is also clear, that since much water exists in the earth, and moves with a certain freedom through strata, we may chance to cut strata that will, if passed through, let down much water to the work below, even if in the works themselves there is not a natural and great accumulation of water. Under any circumstances, extensive works carried on at any considerable depth below the surface will certainly need support and probably drainage.

Lastly, it will not be difficult to understand that a free circulation of air is necessary for carrying on the works, more especially when they are deep and extensive. Thus the system of mining must have reference to the nature of the roof and the depth of the mine, to the drainage of the mine, and to the ventilation. In order to reach the mineral, it is generally necessary to sink a pit or shaft, an operation the expense and difficulty of which depend on local circumstances.

In mining for ores that exist in mineral veins, there is often little difficulty in regard to the roof, as the ore fills up a gap which has no tendency to close, and, shafts being frequent for the sake of getting the ore, there is seldom much trouble with ventilation. Drainage in such cases is, however, generally of primary importance.

The mining operations, when access is once obtained to a deposit of valuable mineral, must be regulated by the hardness, toughness, and condition of the mineral. Coal can be removed by undermining or underholing, that is by cutting a deep groove at the bottom of the bed, and using wedges to make it fall. Ores are generally obtained by blasting, or by *pick and gad*—the pick and small iron wedges called gads being the common tools of the miner. Once obtained, the produce has to be carried along to the shaft, and then lifted to the surface—operations less simple than they at first appear, but not requiring special notice in this place.

The drainage of mines is effected generally

by a mixed system, the water being carried off as far as possible by natural drains to as low a level as circumstances admit [ADRR], and the rest pumped by powerful machinery or lifted in iron buckets, according to the quantity and magnitude of the works. Steam is largely employed in draining, and the same lifting power is made use of to remove the mineral to the surface.

Ventilation is carried on in coal mines by a system of subdivision of the work, and by placing walls and doors to insure a current of air throughout. The air is generally drawn into the mine at one shaft, by converting another into a chimney and placing a furnace at the bottom to insure a draught.

The roof of a coal mine always requires careful attention. At first only so much coal is taken as to leave sufficient support. The roof of the galleries thus made is propped, and the rest of the coal is then removed carefully. Ultimately the roof is allowed to fall.

In metal mines a number of shafts are sunk, generally in or near the lode, or through rocks to cut it. The shafts are much more numerous than in coal mines, and often pay for their cost. The ore is removed in successive levels, beginning from below wherever it is found. The walls are left.

Minion. In Printing, the name of a kind of type, one size smaller than that used in this work. [TYPE.]

Minister (Lat.). In Politics, a servant of the sovereign executive power in a state: generally speaking, the head of a department or branch of government. Usage, in different countries, fixes very differently the limits of that higher class of servants to which the term is applied. In the British Empire, none but the heads of administrative departments are termed ministers: part of whom belong to the cabinet; and part are not included in it. The cabinet ministers have varied under different administrations; and as our government is of mixed organisation, partly to serve the actual necessities of state, and partly retaining ancient distinctions of office founded on usage only, some of the ministers hold merely sinecure appointments. In France, where the forms of government are established more on the principle of utility, there were under the Restoration eight ministers so called: 1. of the interior; 2. of finance; 3. of justice; 4. of public instruction and ecclesiastical affairs; 5. of commerce and public works; 6. of the marine and colonies; 7. of war; 8. of foreign affairs; to which the empire has added a 9th, *of the Imperial household*. In England, ministers sit and vote in either house of parliament—by hereditary right, if peers; as representatives only, if commoners. In France, ministers have also, by virtue of their office, a right to sit and take part in the debates in either chamber. In the United States, no minister (or secretary, in the language of that government) can be either representative or senator. In

some European countries (as Russia), a distinction is established between the private affairs of the sovereign and foreign affairs, on the one hand, which form the combined duties of the cabinet ministers; and the affairs of the interior, which are intrusted to ministers of state. There are also in some governments honorary or *conference* ministers, without any real department of duty. The representatives of minor sovereigns at foreign courts are usually styled *ministers*, instead of *ambassadors*. The term *minister* is also frequently used in a sense synonymous with *clergyman*.

Minium (Lat.). Red Lead. [LEAD.]

Minnehöfe (Ger.; literally *courts of love*).

The name given by the Germans to the courts of love, famous in the history of chivalry. The subjects brought before these courts were chiefly connected with the Romantic gallantry of the period, and consisted either of questions proposed with the view to entrap the judges into some awkward decision, or of serious complaints, resulting from affairs of the heart, which were discussed with all the formality of a court of law. These minnehöfe were for a long period looked upon as forming an indispensable part in all chivalrous exercises. Knights, ladies, and poets alike participated in their proceedings; and large collections of their decisions are still extant. A certain number of ladies acted as judges in these courts, and conducted the proceedings as counsel; they were attended by a train of nobles, knights, and others, who were invested by the court with gradations of precedence analogous to those conferred by the sovereign. These courts were held periodically at Signes, Avignon, Lille, and Pierrefeu. The last regular court of this kind was celebrated by Charles VI. and his wife Isabella of Bavaria; but they were now and then renewed at irregular intervals, and the last on record took place as late as the reign of Louis XIV. We subjoin a few specimens of the questions proposed in these courts for debate and decision. 1. Which is harder to bear—the infidelity or the death of the beloved? 2. Whether does a man whose wife, or a lover whose betrothed, is unfaithful, suffer most? 3. Who is more culpable—the man who boasts of favours from a lady which he never received, or he who having really received them makes it known?

Minnesingers. The most ancient school of German poets, whose name is derived from the old German word *minne* (*love*). The songs and fame of the Provençal troubadours appear to have penetrated into Germany under the first emperors of the house of Hohenstauffen; in whose time the crusades afforded the frequent Italian wars combined to bring their nation, seated as it is in the centre of Europe, in closer communication with those surrounding it. The minnesingers imitated in German the strains of those early poets, and, like them, made love their principal subject; which was celebrated with much of pedantry and false conceits, but, at the same time, not without

generous and chivalric feeling. The verses of the minnesingers are in the old Suabian dialect of the High German, which, under the Hohenstauffens, themselves of Suabian race, was the court language. As was the case with the troubadours, the minnesingers belonged to two different classes: there were among them many knights, princes, and even sovereigns; while there was also another class of more professional poets—wandering minstrels, who attached themselves to the persons of distinguished chiefs, or wandered from court to court. The oldest of the minnesingers known to us is Henry of Veldeck, about 1170. During the remainder of the twelfth and first half of the thirteenth century this school of poets flourished; afterwards it gradually declined, and was succeeded by the less chivalrous and homelier school of the master-singers. We possess the names of more than 300 poets, and pieces of the composition of a large proportion of them, who sang during the short period in question. The German amatory poets had their high and low minne, like the celestial and popular Aphrodite of the ancients; the former an abstract and chivalric devotion to a beloved object, the latter a less elevated passion. The ancient German national epic, called the *Nibelungen Lied*, and the heroic poetry of the *Heldenbuch*, belong to the same period and dialect, and were works of the same race of poets; as were also other poetical romances, founded on the foreign traditions of France, Brittany, and classical antiquity. (*Edinburgh Review*, April 1862, p. 359; *National Review*, July 1858, p. 74.)

Minnow or **Minim** (Lat. *minimus*, *least*). The name of a species of Cyprinoid fish (*Leuciscus phoxinus*, Cuv.), and the smallest of the British species of that family. It inhabits many of the fresh-water streams and canals in England, and spawns in June, when each female is attended by two males.

Minor. In Music. [MAJOR.]

Minor Determinants. [DETERMINANTS.]

Minor Term of a Categorical Syllogism. In Logic, the subject of the conclusion. The minor premiss is that which contains the minor term. In hypothetical syllogisms, the categorical premiss is called the *minor*.

Minority. In Law. [AGE.]

Minority. In Politics, the period during which the sovereign in an hereditary monarchy is incapacitated from exercising the supreme authority by reason of not having attained the age prescribed by law; also the state of such incapacity. The royal authority, in hereditary monarchies, never dies; and when a sovereign deceases leaving a successor below age, it passes immediately to the person or persons whom the constitution has invested with the authority of regent; as it also does when a king becomes subject to any other incapacity. The term of royal minority is variously regulated by the constitution of different countries. The legal majority of a king of France was fixed at fourteen by an ordinance of Charles V.,

which has been since followed in that country; but, as a year commenced is reckoned as accomplished, the actual period at which a king of France begins to govern is the age of thirteen years and a day. The same period is fixed by the laws of Spain and Portugal. By the constitution of Great Britain the sovereign is of full age at eighteen years, as far as can be collected from the statutes passed at several times to empower the king to name a regent whenever it has been apprehended that the crown was in danger of devolving on a prince under age.

Minos. In Mythology, a son of Zeus and Europa, and king of Crete. After his death he became judge of the infernal regions, along with Eacus and Rhadamanthus. For the meaning of the name, see *MESEU*.

Minotaur (Gr. *μινόταυρος*). In Mythology, a monster, half-man and half-bull, said to be the son of Pasiphaë, wife of Minos, king of Crete, by a bull (*ταύρος*); hence the term *Minotaur*. According to one version of the myth, Minos shut him up in the labyrinth of Dædalus, feeding him with criminals, and afterwards with youths and maidens sent from Athens. Theseus, by the assistance of Ariadne, succeeded in destroying him, and thereby rescued the Athenians from the obligation of sending their children to be devoured. The bull of Minos, whose wife is Pasiphaë, the *giver of light to all*, is seen again in the bull of Indra, as well as in that which bears Europa across the sea. In some myths, as in that of the Marathonian bull, the only idea attached to it is that of devastation; but the Marathonian bull, like the Minotaur, is slain by Theseus, who is also a solar hero.

Minster (Ger. *münster*, Gr. *μναστήριον*). In England this term was originally applied to the outposts of the Christian Church, maintained by bodies of priests living under rule in those isolated stations which have ever since that time retained the maternal title of minster. These minsters were not necessarily parish churches, although they might become the parents of many such churches. Thus every station, in the advance made by the fellow-labourers of Augustine, received the name of *monastery* or *minster*, and retained it long after the place of the monks had been filled up by secular priests. (Earle's 'Gloucester Fragments,' *Edinburgh Review*, Oct. 1862, p. 420, &c.)

Minstrels (Fr. *ménéstrel*, from Old Ger. *minne*, *love*). Minstrels are defined by Percy as an order of men in the middle ages who subsisted by the arts of poetry and music, and sang to the harp verses composed by themselves or others. They appear to have been the successors of the minnesingers, scalds, and bards of different European nations, who, even after the age of chivalry had passed, attempted to gain a subsistence by practising those arts which at an earlier period had procured fame and honour for their predecessors.

In times of peace (to follow the sketch of

MINSTRELS

a writer in the *Edinburgh Review*, vol. lxxiii.) the minstrel, *omnis luxuria interpres*, as Pliny said of Menander, sang of mimic war to the dull barons of dungeon castles, who had ears, although they could not read—who, steeped in the weariness of wealth and want of occupation, listened greedily, like other great men, to their own praises. Minstrelsy supplied the lack of a more refined intellectual entertainment and of rational conversation, as professional gentlemen do now at civic banquets: their harpings lulled the rude Sauls to sleep, which is now done by quarto epics. The person of the minstrel was sacred; his profession was a passport; he was 'high placed in hall a welcome guest:' the assumption of his character became the disguise of lovers of adventure. These advantages raised pseudo-laureates, *idles vagabonds*, according to the Act of Edward I., 'who went about the country under the colour of minstrelsy;' men who cared more about the supper than the song; who, for base lucre, divorced the arts of writing and reciting, and stole other men's thunder. Their social degeneracy may be traced in the dictionary: the chanter of the *gests* of kings—*gesta ducum regumque*—dwindled into a *gesticulator*, a jester; the honoured jogler of Provence into the mountebank, the juggler, the *jockie*, or doggrel balladmonger.

Beggars they are by one consent,
And rogues by Act of Parliament.

They descended by the usual stages of things of mere fashion; at first the observed of all observers, and therefore imitated, until they became common—vulgar; a step which is at once the test of merit and universal acceptance, and the forerunner of disgrace. In Spain, particularly, this fall occurred very soon. The really good clergy were shocked at their abuses, while the interested grudged the money earned by rivals who interfered with their monopoly of instructing the people in pious or of amusing them with alexandrine

1. Their Latin synonym for *scald* is—*sourra mimus*, &c.—will outlive their sculptured caricatures, in which mendicant monks, minstrels, fools, and monkeys, are pilloried on pinnacle and gargoyle, in cloister and cathedral. The itinerant monks and mountebanks repaid all this, like Falstaff, by showing up the irregularities of regulars and seculars, 'in ballads to be sung to filthy tunes.' They undermined their influence. Preachings and songs take part in all national changes; for doctrines precede actions. They were the popular press of the time; opposed by the privileged orders, and watched by statesmen, as Bury afterwards employed agents to listen to street songs—the thermometer of the people's temper. In all these alterations for the worse, the primitive principle 'to entertain' remained unchanged. To this original ballad was sacrificed; passing from one to another, each minstrel begged, borrowed, or stole from all

MINT

quarters. As late as the beginning of last century the houses of many leading families, especially in the northern parts of the empire, were provided with minstrels, who were employed in various duties; all of them, however, in some degree connected with their original occupation. [BARD; SCALD; MINNESINGERS; BALLAD.]

Mint (Ger. *münze*, Dutch *munte*). The place in which the coin of the realm is manufactured. The whole of the British coin is issued from and manufactured at the Royal Mint in London. The general details of the business of the Mint are briefly stated under the article COINAGE.

The Royal Mint received its constitution of superior officers in the eighteenth year of the reign of Edward II., and continued nearly as then established to carry on its operations within the Tower of London.

Between the years 1810 and 1815 the present building was erected 'on Tower Hill, at the suggestion of a committee of the king's privy council, appointed in 1798 'to take into consideration the state of the coins of the kingdom, and the establishment and constitution of the Mint;' and in 1815 a new constitution was introduced, founded upon a report drawn up by Lord Maryborough, who was then master.

Under that constitution the chief officers of the Mint were the master, the deputy master, the comptroller, the king's (or queen's) assay master, the clerk of the papers, and the clerk of the irons and superintendent of machinery: these constituted the *Mint board*, and met as often as required, to transact all the general business of the establishment. The manufacture of the coin was carried on by contract under the direction of a distinct branch of the establishment known as the *Company of Moneyers*. The other officers were the master's assayer, the melter, the chief engraver, the weigher and teller, the surveyor of the meltings, and the solicitor. The duties of these officers are fully set forth in the *Mint indenture*. On the general history of the coinage, the reader is referred to Ruding's *Annals of the Coinage*, and to the article 'Coinage' in the *Encyclopædia Britannica*, which gives an account, illustrated by engravings, of the machinery employed in the Mint. A mass of valuable information, and details respecting the establishment, will also be found in the *Parliamentary Report of the Select Committee on the Royal Mint*, and its Appendix, published by order of the House of Commons, June 30, 1837. In consequence of this report, important changes were made in the mode of carrying on the business of the Mint, more especially affecting the duties and position of the master, and involving the discontinuance of the moneyers' contracts.

MINT (Lat. *mentha*). A name given to several herbaceous aromatic plants belonging to the natural order *Labiata*, and genus *Mentha*. Spearmint, or *Mentha *viridis**, is that which is generally used in cookery. Peppermint, or *Mentha *piperita**, yields the water and the es-

sential oil of pharmacy. Horsemint and others are also — of the same genus. [MIRZA.] (Fr. menuet). A species of dance performed in slow time and with measured steps, formerly very popular, but now rarely if ever met with.

Minute (Lat. minutum, part. of minuo, 1 diminutiv). In the measurement of time, the sixtieth part of an hour; it is represented by the letter *m* in modern astronomical works. In the measurement of an angle, a minute, denoted by a dash or acute accent, is the sixtieth part of a degree, and consequently the 8,400th part of a right angle. It is the angle subtended at the centre of a circle by the 21,600th part of its circumference.

Minute. In Architecture, the sixtieth part of the diameter of a column, by which subdivision architects measure the smaller parts of an order; the diameter is chosen at the lower end of the column.

Minutes. Originally the rough draft of a public instrument drawn up by a notary; so termed because usually written in a smaller character than the instrument itself. The term is now applied to a brief report of the proceedings of a society drawn up by the clerk or secretary: in which sense it is nearly synonymous with *PROCEEDINGS* [which see].

Miocene or Middle Tertiary. The name given to a large and important division of the Tertiary series of rocks, almost absent in the British islands, but extensively developed in the east of Europe, and well shown in France and Belgium. The *Faluns* of the Loire are the typical Miocene beds. The *Sawalik* beds of the north of India are partly at least of this period. The *NAGEL FLUHS* and *MOLASSIN* Swiss deposits are referred to the same age; and several large and important portions of Eastern Europe, especially in the valley of the Danube, consist of rocks of this period.

In Western Europe the Miocene deposits are not of much economic importance, but advancing eastwards, they are not only more extensive, but contain large deposits of mineral fuel, chiefly lignite. The great plains extending from the foot of the Eastern Alps to the foot of the Carpathians are lacustrine deposits of this period, rich in fossils in some localities.

Miquelets. In Modern History, partisan troops raised in the north of Spain, and chiefly in Catalonia. The Miquelets became first known in the wars between Spain and France in the seventeenth century. At several periods (in 1689, 1789, and again in the wars of Napoleon) the French have endeavoured to organise similar corps, to oppose to the Miquelets in the mountain warfare of those districts.

— [SUPERNATURAL.]

(Fr.). An optical illusion very common at sea, especially in high latitudes, and sometimes also witnessed on land, particularly in Egypt and Persia, and on the margin of rivers and lakes, or on the seashore. It arises from the total reflection of the rays of light

from the lower surface of a stratum of air. This can occur when, from any cause, such a stratum of air possesses a higher refractive power than the one immediately below it. Such a condition of the atmosphere causes remote objects to be seen as if reflected in a mirror, or to appear as if suspended in the air. When the effect is confined to apparent elevation, the English sailors call it *looming*; when inverted images are formed, the Italians give it the name of *FATA MORGANA*. Ships in the whale-fisheries are often described, and sometimes known, by means of the mirage, at considerable distances. Captain Scoresby recognised his father's ship at the distance of more than thirty miles, and consequently when below the horizon, by its inverted image in the air, though he did not previously know that it was cruising in that part of the fishery. The mathematical theory of the phenomenon is given by Biot, in the *Mémoires de l'Institut* for 1809. (Caddington's *Optics*; Biot's *Traité de Physique*, tome iii.; Brewster's '*Optics*,' *Cabinet Cyclopædia*.)

Mirmillones. In Roman Antiquity, a species of gladiators, who fought completely armed against the *Retiarii*. Their arms consisted of a sword, headpiece, and shield. On the top of the headpiece they wore a fish embossed, called *mormyr* (Gr. *μωμύρας*); whence the name. The Mirmillones were also termed *Galli*, from their wearing Gallic armour; and *Scutatores*, from the shield by which they were defended.

Mirror (Fr. miroir). A speculum or looking-glass, or any other polished body capable of reflecting the images of luminous or illuminated objects. Silver is the most powerful reflector, absorbing only 9 per cent. of the incident light; whilst speculum metal reflects only about 63 per cent. of the incident rays. In the very early ages of the world, polished metallic specula, especially of brass, were employed as mirrors by the Jewish and Egyptian women; but in modern times, plates of glass coated on one side with an amalgam of tin are alone used as mirrors for ordinary purposes. [MERCURY; TIN.]

Concave mirrors are sometimes used to concentrate the rays of the sun or of ignited bodies to a focus, and thereby produce intense heat. The surfaces formed by the revolution of the ellipse, parabola, and hyperbola are such that the first accurately reflects divergent rays to a focus, the second parallel rays, and the third divergent rays. The great difficulty of constructing these surfaces has led to the employment of spherical segments, which, though not accurate, yet under proper restrictions are approximately so. For the mathematical theory, see REFLECTION; see also BURNING GLASS; SPECULUM; TELESCOPE.

Mirza (a corruption of the Persian title *Emir-Zadeh*, *sons of the prince*). The common style of honour in Persia, when it precedes the surname; when appended to it, it signifies prince.

MISCHNA

Mischna. The text of the Jewish Talmud, on which the *Gemara*, or second part, is a commentary. It consists of traditions and explanations of Scripture. The former are supposed by the Jews to have been delivered to Moses on the mount, and from him to have passed, through the keeping of a succession of prophets and sages, to Rabbi Juda of Tiberias, who committed them to writing. Their compilation is supposed by modern commentators to have taken place about A.C. 150 or 190. (Frideaux, *Connection*, vol. ii.; and Lardner, *Collection of Jewish and Heathen Testimonies*, vol. i.)

Misdemeanour. In Law, any offence which is the subject of indictment and punishment, not of a felonious character; such are seditious acts, perjury, battery, libels, conspiracies, attempts, and solicitations to commit felonies, &c. Over these offences the justices of the peace at quarter sessions have a general jurisdiction, although they may be removed by certiorari to the Queen's Bench; and in the trial the defendant had at least for a long period of time one remarkable privilege, viz. that his counsel might address the jury, which was equally the case in treason, but not until the year 1837 in any sort of felony. The ordinary punishment of misdemeanours is by fine and imprisonment. [LAW, CRIMINAL; MISPRISON; SESSIONS.]

Misénite. A hydrated sulphate of potash found in the form of white silky fibres in a cavern near Misene in the Campagna.

Misericordia (Lat. *pity*). A dagger, so termed in the middle ages because it was the weapon used by a knight against a dismounted adversary when he enforced him to cry for mercy. [DAGGER.]

Misnomer. In Law, the description of a person by a wrong name. This error was fatal under the rigour of ancient English law in various instances, but may now generally be amended in proceedings both civil and criminal.

Mispickel. Native arsenide with bisulphide of iron, of a tin-white colour, with a metallic lustre. It occurs chiefly in lodes in crystalline rocks, and was formerly worked in Cornwall as an ore of arsenic, much of the white arsenic of commerce being obtained from it. (Bristow's *Glossary of Mineralogy*.)

Misprision (from the Fr. *mespris*, *contempt* or *negligence*). In Criminal Law, in its larger sense, this term is used to signify every considerable misdemeanour which has not a certain name given to it in the law; and it is said that the offence of misprision is involved in every treason or felony whatsoever. Generally, however, by the word *misprision* is understood the contempt or neglect, that is, the non-disclosure or concealment, of any treason or felony, committed or to be committed, which a man is cognisant of, but has never assented to; for if he expressly assented, this makes him, in a case of treason, a principal, and in a case of felony either a principal or accessory, according to circumstances. Misprision of treason was made punishable under ancient statute by loss

MISSIONS

of the profits of lands during life, forfeiture of goods, and imprisonment for life. Misprision of felony in a public officer is punished by imprisonment for a year and a day; in a common person, by imprisonment generally; and in both by fine.

Missal (Low Lat. *missale*). The book containing the ritual for the celebration of the various masses of the Roman communion. The missals in use in different churches are not identical in all respects; but the most important part of them, the canon of the mass, as delivered in the Sacramentary of Gregory the Great, which was taken from that of Pope Gelasius in the fifth century, and which is affirmed by Roman Catholics to be a faithful representation of the ritual of the primitive church, is common to all.

Missionaries (Lat. *missio*, a *sending*). In ordinary language, ministers who go abroad to preach the Gospel to infidel nations. For the fields of labour, titles, and operations of the principal missionary societies now existing in and out of Great Britain, see SOCIETY.

Missions. Stations of missionaries in infidel countries. In Geography, the extensive districts formerly under the control of missionaries of the church of Rome, on the borders of the Spanish and Portuguese settlements in America, were so called. These missionaries chiefly belonged to the orders of the Capuchins, Dominicans, and Jesuits; but the latter were the most celebrated and the most successful. Their settlements in Paraguay comprehend a vast province, which they governed with independent authority: in Brazil they had also extensive districts under their control. The downfall of the order was followed by the destruction of these settlements: those of Paraguay were wholly ruined; those of Brazil, by regulations of the marquis de Pombal, were taken from their spiritual governors and placed on a new footing. Trifling relics of the missions of the other orders are still found on the banks of the Upper Amazon and Orinoco; but they have undergone severe losses from the revolutionary wars. The success of the experiment of governing the American Indians by missionaries has been the subject of much controversy. It is certain that the Jesuits succeeded better than any other governors have done in rendering them industrious, and subjecting them to discipline. But it is contended that this was only effected by an artificial system, which rendered them the servile and childish dependants of their spiritual masters, and that this slavish state was injurious to them, not only in a moral but a physical point of view, inducing premature decay; inasmuch that, it is said, the population of all the missions was continually decreasing, although endeavours were made to keep it up by violent seizures of free natives, who were brought by force within their boundaries. See Charlevoix, *Histoire du Paraguay*; the *Lettres Édiifiantes*; Raynal, *Histoire des Indes*; and Southey's *History of Brasil*: the two last writers espou-

MIST

cially for philosophical views on the subject, although the latter is perhaps too favourable; Marshall's *Christian Missions*; Humboldt's *Personal Narrative*, for those on the Orinoco; Forbes's *California*, for a very unfavourable view of the condition of those in the latter country, prior to the American annexation of the greater part of it. American missionaries have established a government, somewhat similar to those of the Roman Catholic orders, in some of the South Sea Islands. See Ellis's *Polynesian Researches*; the *Voyages* of Adm. Beechey, Capt. Erskine, and others.

Mist. [Fog.]

Mistletoe (A.-Sax. *misteltan*). A parasitical plant inhabiting the branches of many kinds of trees in the north of Europe. It is the *Viscum album* of botanists. Its connection with Druidical ceremonies is well known; but, as tradition tells us that the priests of that superstition only employed the mistletoe of the oak, some doubt had been entertained of the plant now so called being really that of our ancient chronicles, because it had not been found upon the oak for many centuries. It has, however, been recently discovered upon that tree in the west of England; and this leaves no doubt upon the subject. The powder of the leaves or shoots of the mistletoe has been used in epilepsy. [*Viscum*.]

Mistral. The name given to a cold north wind, which, blowing from the Alps, forms one of the scourges of Provence and the valley of the Rhône. It blows with great violence during the winter and spring months.

Misay. An impure sulphate of iron, occurring in opaque pulverulent masses of a yellow colour at the Rammelsberg mine in the Harz.

Mites (Fr. *miton*, Old High Ger. *miza*, Gr. *μῖτα*). A tribe of minute Acaridan Condylolops, which do not suck their food. [*Acarus*.]

Mithras. The sun-god of the Persians, to which they paid adoration as the purest emblem of the divine essence. The worship of Mithras was introduced into Rome, seemingly not long after the fall of the republic, and soon spread over all parts of the empire. It was one of those which resisted Christianity the longest. The god is commonly represented as young, and kneeling on a bull which he has thrown on the ground, and which is also attacked by a dog, a serpent, and a scorpion. A specimen of such a group is preserved in the British Museum. The bull reappears in the legends of India and Europe; the serpent in those of Heracles, Vritra, Orpheus; and the dog in those of Artemis, Kephelos, Procris, &c. all solar myths. (Beugnot, *Destruction du Paganisme en Occident*; Milman's *History of Christianity*.)

Mithridate. A celebrated medicinal confection, said to have been invented by Damocrates, physician to Mithridates, king of Pontus, and supposed to be an antidote to all effects of poison and contagion; it contained seventy-two ingredients. This many-headed monster of Pharmacy is (says Dr. Heberden) a farrago

MIZZEN MAST

that has no better title to the name of Mithridates than as it resembles the numerous undisciplined forces of a barbarous king, made up of a dissonant crowd, mighty in appearance, but in reality an ineffective multitude that only hinder each other. (*Antithieriac*, 1746.) An amusing account of this once celebrated remedy will be found in the Introduction to Dr. Paris's *Pharmacologia*.

Mitral Valves. The valves of the left ventricle of the heart.

Mitre (Lat.; Gr. *μίτρα*, a head band, or *diadem*). The episcopal coronet. It appears to have been an ecclesiastical head covering from the earliest ages of antiquity. Pellerin says that it was worn by the regal pontiffs of the Hebrews, and with a few slight modifications was afterwards adopted by the Oriental kings and pagan high priests under the name of *cidaris*. Among the Romans the mitre was originally a sort of head-dress worn by ladies; and Servius makes it a matter of reproach to the Phrygians that they were dressed like women, inasmuch as they wore mitres. There is every reason for supposing that in England the mitre was worn by the bishops on the first introduction of Christianity into the island; and it is supposed (Gough's *Sepulchral Monuments* vol. i. p. 153) that the practice was borrowed from the apex or tutulus of the Flamen Dialis in ancient Rome. As an heraldic ornament, the mitre of a bishop is surrounded by a fillet set with precious stones: the archbishop's mitre, on the other hand, issues from a ducal coronet.

Mitre. In Architecture, a junction of two pieces of wood or other material at an interior angle, by diagonal fitting.

Mitre Wheel. In Machinery, the term *mitre wheel* is applied to wheels that have their teeth set at 45° with the spindle, so as to transmit the motion to another mitre wheel and shaft placed at right angles to the first wheel.

Mittimus (Lat. *we send*). In Law: 1. A writ for transferring records from one court to another; 2. A precept under the hand and seal of a justice of peace committing an offender to his charge. [*Commitment*.]

Mixed Cadences. In Music. [*Cadence*.]

Mixed Differences. [*Equation of Mixed Differences*.]

Mixed Number. In Arithmetic, the sum of a whole number and a fraction. In the symbol for a mixed number the sign + is usually omitted; thus $3\frac{1}{2}$ denotes $3 + \frac{1}{2}$. A mixed number can always be expressed as an improper fraction, and vice versa.

Mizzen Mast. The name given in a three-masted vessel, or in a ketch or yawl, to the mast which supports the after sails, being nearest the stern of the ship. The word occurs in Italian as *mezzana*, a lateen sail, and in French as *misaine*, a foresail, and must be traced to the Latin *medius*, and the Greek *μέσος*; its application arising from the mizzen sail in a galley being in the *middles* line of the ship, while the other sails were carried across the deck.

MNEMONICS

(Gr. *μνημονικός*, from *μνήμη*, *memory*). The art of refreshing the memory in particular things by artificial aids. The common processes of tying a knot in a handkerchief, &c., will exemplify the simplest species of mnemonics, in which we endeavour to connect certain arbitrary acts with peculiar associations, so that the memory of the former may call up the latter. Some persons have taken the precaution, before delivering an address by heart, of entering the room in which it was to be spoken, and connecting in their own minds particular portions of their intended language with certain visible objects in the room. The well-known solemnities observed on the perambulation of parish boundaries, &c., form another instance of practical mnemonics, the object being to fix the memory of particular spots in the mind of those who are present. For the purpose of facilitating the remembrance of dates, names, &c. various methods have been devised by different writers (especially Feinagle and Gray in England) under the names of *Memoria Technica*, or *Artificial Memory*.

Mnemosyne (Gr. *μνημοσύνη*, *memory*). In the Hesiodic *Theogony*, a daughter of Uranus (the heaven) and Gaia (the earth), who became by Zeus the mother of the nine muses.

Moot (Ital. *mots*). A ditch made round the old castles, and filled with water. In some cases these moats still remain, as at Bodiam Castle; whilst in others they are drained and planted, as at Eltham Palace. For the most part, however, all traces of them have disappeared.

Mobility (Lat. *mobilitas*, from *moveo*, *I move*). One of the general properties of matter, in virtue of which every body at rest can be put in motion by the action of a source adequate to overcome its inertia.

The term is also frequently used to denote the absence of viscosity or oiliness in liquids; thus water, alcohol, and ether are said to be mobile, whilst castor oil and molasses are viscid liquids. [MATTER.]

Moccasins. The native name for the shoes of the American Indians. They are generally made of deer skin or other soft leather, without a sole, but ornamented on the upper side.

Mocha Stone. A white translucent kind of Agate with brown markings resembling trees and vegetable filaments. The name is, probably, a corruption of *Moschus* (or moss) Stone.

Mocking Bird. A name given to one of the family of thrushes, the *Turdus polyglottus* of Linnaeus, on account of the surprising facility and accuracy with which it can imitate almost any sound. It is also the finest of song-birds; and the vocal organs, which are well developed in all the thrush tribe, find their highest perfection and complication in the mocking bird.

This species, in modern ornithological systems, forms the type of a genus (*Mimus* of Boié): it includes other species besides the *M. polyglottus*, all of which are natives of America. [MIMUS.]

MODELLING

Modality. In Logic, a term applied to designate propositions in which the copula is accompanied by some phrase which adds to or restricts its meaning. Some of those phrases may be thrown into a logical shape by altering the form of the proposition. Thus the modality expressed by *must* is only the expression of a universal statement, 'Body must occupy space' being equivalent to the proposition 'All bodies occupy space.'

Mode (Lat. *modus*). A term used by Locke to denote 'such complex ideas which, however compounded, contain not in them the supposition of subsisting by themselves, but are considered as dependencies on or affections of substances.' Of these modes there are two kinds—*simple* and *mixed*. Simple modes are 'only variations or different combinations of the same simple idea, without the mixture of any other, as a *dosen* or a *score*, which are nothing but the ideas of so many distinct units added together.' *Mixed modes* are those 'compounded of simple ideas of several kinds put together to make one complex one—e. g. *beauty*; and consisting of a certain composition of colour and figure, causing delight in the beholder.' It need hardly be said that this distinction is founded on a very imperfect and false analysis. The term is now universally laid aside by writers on mental philosophy.

Mode. In Music, the melodious constitution or arrangement of the scale of the octave. Thus we speak of the major mode when the notes of the octave are arranged according to the major scale, and of the minor mode when they are arranged according to the minor scale.

Model (Fr. *modèle*, Ital. *modello*, from Lat. *modulus*, dim. of *modus*, a *measure*). In the Fine Arts, that which is an object of imitation. In Painting and Sculpture, it is the individual whom the artist procures for getting up his proportions, details, play of the muscles, &c. In Sculpture, the term is applied to the small sketch in wax or clay for a work of art. In Architecture and in manufacturing art, it is a small pattern in relief, either of wood, plaster, or other material, of the building proposed to be executed.

Model. In Mechanics, a small or miniature representation of the structure of a machine, so as to exhibit its mode of working, &c. Owing to the effect of increased mass in making the machine itself, the results obtained from the model exceed those of the machine in a greater ratio than the linear dimensions of the two works.

Modelling. In the Fine Arts, the art of forming figures in wax or in clay for making the mould from which works in plaster or other material are to be cast. In modelling in clay, that is potter's clay, the tools used are made of wood and of wire, but no tool is so good as the fingers. The clay, kept of a certain uniform moisture by constant sprinkling, or by being covered with a wet cloth or with oil-silk or an air-proof bag, is placed on a banker with

MODERATORS

a circular revolving plinth, for the convenience of the manipulator. Clay models require interior supports, composed of a strong iron upright, and sometimes even wood also with cross bars, or the work is liable to sink or even fall to pieces, from the weight of the wet earth: the proper construction of these skeleton supports is a very essential part of modelling in clay.

Goldsmiths and medalists use wax for their models, which are commonly of a comparatively small size: the same material was used by the ancients for their small bronzes. Modelling wax consists of bees-wax melted with a small quantity of Venice turpentine, with which a little flake white in powder, or other powdered colour, is mixed, according to the tint or colour required. In wax modelling, ivory tools as well as wood are used.

Moderators, Senior and Junior. In the Universities of Oxford and Cambridge, certain public officers appointed annually to perform various duties. Their name is derived from their old office of moderating or presiding in the exercises publicly performed in the schools between undergraduates candidates for the degree of bachelor of arts. These disputations, relics of the old university system, are now reduced to little more than matters of form. *Moderator* is also the name applied to the president for the time being of the General Assembly of the Church of Scotland, and of the other inferior church courts, the synods, and presbyteries.

Modillion (Fr.). In Architecture, an ornament sometimes square on the profile and sometimes scroll-shaped, thus , with the intervention of one or two horizontal members, placed at intervals under the corona in the richer orders. They should stand centrally over columns when the latter are employed. They are simplest in the Ionic and Composite orders, much more carving being bestowed on them when they are introduced in the Corinthian. The mutule of the Doric order, which should always stand over the centre of a triglyph, is the same sort of thing as the modillion, and occupies the same place in the entablature.

Modular Focus of a Quadric Surface. In Geometry, a point-sphere which has double contact with the quadric of such a kind that the planes of contact and intersection are imaginary. The locus of all such points is called a *modular focal conic*. When the planes of contact are real, the point-sphere is often termed a *non-modular* or *umbilical* focus. MacCullagh first introduced these terms in his theory of the *modular generation of a quadric*, which theory was afterwards completed by Dr. Salmon. [FOCUS.]

Modulation (Lat. *modulatio*, a measuring). In Music, the act of moving through the sounds in the harmony of any particular key to those of another; or the transition from one key to another.

(Lat. *modulus*). In Architecture,

MOHAMMEDANISM

measure equal to the semidiameter of a column. It is by some writers exclusively applied to the Doric order; but its application

Modulus (Lat.). A term often, and sometimes loosely, used in Mathematics; in general it denotes some constant, multiplier, coefficient, or parameter involved in a given function. Thus we have the *modulus of a system of logarithms*, the *modulus of a congruence*, the *modulus of an elliptic function*, the *modulus of linear transformation*, &c., all which terms will be found defined more strictly in their respective places. Again, the positive square root of $a^2 + b^2$ is often termed the *modulus of the imaginary expression* $a + b\sqrt{-1}$; in the theory of numbers, however, $a^2 + b^2$, the square of this modulus, is called the *norm*. [INTEGER.]

Modus (modus decimandi, or special manner of tithing). In Law, a term used where lands, tenements, or some certain annual sum or other profit, hath been given time out of mind to a person and his successors in full satisfaction and discharge of all tithes in kind. It is in some cases a pecuniary compensation, in others compensation in work and labour. [TITHES.]

Moeres. [MOIRA.]

Mograbians or **Men of the West.** A name formerly given to a species of Turkish infantry composed of the peasants of the northern parts of Africa, who sought to better their condition by entering into foreign service.

Mogul, Great. The name by which the chief of the empire so called, founded in Hindustan by Baber in the fifteenth century, was known in Europe. The last person to whom this title of right belonged was Shah Allum; and the Mogul empire having terminated at his death in 1806, his vast possessions fell chiefly into the hands of the East India Company.

Mohair (Ger. *mohr*, Fr. *moire*, Ital. *moerro*, Span. *muer*). The hair of a variety of the common goat, famous for being soft and fine as silk, and of a silvery whiteness. It is not produced anywhere but in the vicinity of Angora, in Asia Minor. The exportation of this valuable and beautiful article, unless in the shape of yarn, was formerly prohibited; but it may now be exported unspun. The production, preparation, and sale of mohair have long engrossed the principal attention of the inhabitants of Angora; and it used to form an important article of Venetian commerce. It is manufactured into camlets and other expensive stuffs. Hitherto but little has been imported into England.

Mohammedanism. One of the most celebrated systems of religion in the world; so called from Mohammed, its author and founder, who was born at Mecca, in Arabia, in May 571. This founder of a new religion and of a political power, which even in his lifetime extended over his native country, and which under his successors threatened to overrun the world, traced his genealogy in a direct

MOHAMMEDANISM

line through eleven descents from Koreish, the founder of the powerful tribe that bore his name, and who again was affirmed to be in direct descent from Ishmael, the son of Abraham. The future prophet sprang, therefore, from the noblest tribe of the Ishmaelitic Arabs; and his grandfather was at the time of his birth sovereign of Mecca, and guardian of the *Caaba* (which from time immemorial had been identified in the minds of the Arabs with every sacred feeling); consequently, from the sanctity of his territory and his office, a prince of great power and influence. But though descended from so powerful a family, Mohammed's early life was spent in comparative dependence. He was a younger son of Abd al Motaleb; and having in his early infancy lost both his parents, his only inheritance was five camels and a female slave. On his paternal grandfather was devolved the guardianship of the future prophet; but of this protector he was deprived by death when only eight years of age. In a dying charge Motaleb confided this tender plant of the ancient stock of the Koreish to the hands of Abu Taleb, his eldest son, and the successor of his authority, who amply redeemed the trust reposed in him by continuing throughout life the steadfast friend of his ward amid all the difficulties and dangers to which the latter was exposed in the promulgation of his doctrines. His education, however, is said to have been extremely scanty; and at the early age of thirteen, being intended for a commercial life, he accompanied his uncle's trading caravan into Syria. He afterwards entered into the service of Khadijah, a rich widow of Mecca, to whom his skill in commerce or his other accomplishments so far endeared him that at the end of three years she bestowed upon him her hand and fortune—an alliance which restored him to the station of his family. At this period he was twenty-five, and his wife forty years of age.

During the first thirteen years of his marriage little or nothing is known of his history; but at the end of that period he withdrew from society to a cave near Mecca, where he gave himself up to contemplation. In this retirement he gave out that for two years he was in daily communication with the Deity.

In his fortieth year he assumed the prophetic office, and displayed his views and principles to his domestic circle. His first convert was Khadijah, whom he always regarded with affection, and even reverence, and whom he placed, after her death, among the only four perfect women the world ever saw; the other three being Miriam, the sister of Moses; the Virgin Mary; and Fatima, the youngest of his own daughters. The progress of the new sect was at first very slow. Three years were silently employed in the conversion of fourteen (some say nine) proselytes; but in the fourth year he extended the theatre of his preaching, and proclaimed his doctrines publicly to his fellow-citizens. The faith which, under the name of Islam (i.e. salvation), he preached, was compounded substantially of two great principles,

which, as Gibbon says, involve an eternal truth and a necessary fiction; namely, that 'there is only one God, and that Mohammed is His prophet.' He did not, however, aim so much at founding a new religion as reforming the old, as declared by the former prophets, Adam, Noah, Abraham, Moses, and Christ, by putting an end to those superstitions and idolatries by which the true faith had been corrupted. Being urged to confirm the reality of his divine mission by miracles, he declined the attempt, appealing to the internal evidence of his doctrines, and declaring that miracles would depreciate the merit of faith. The only miracle which he professed to have accomplished is a nocturnal journey from Mecca to Jerusalem, and thence through the heavens, on an imaginary animal called Borak, i.e. lightning; but the words of the *Koran* are often regarded as figurative and allegorical. The citizens of Mecca listened to the exposition of his principles with patience till he attacked the idols of the *Caaba*. This, however, raised such a storm against him, particularly on the part of the Koreishites, that, notwithstanding the protection of Abu Taleb, who, though not converted to Islamism, continued the warm and steadfast protector of his nephew, many of his followers fled to other countries, chiefly to Ethiopia. This happened in the sixth year of his mission, and is called the *first Hégira*, or flight.

In the tenth year of his mission he lost both his wife Khadijah and his uncle Abu Taleb. The death of the latter being the severest blow that the new faith had yet sustained, this year is known in the Mohammedan annals as 'the year of mourning.' The death of Abu Taleb removed the only check to the virulent enmity of the Koreishites; and a stranger having succeeded to the sovereignty of Mecca, Mohammed (after a troubled residence of three years, marked, however, by the accession of many proselytes), on the invitation of a deputation from Medina, fled to that city; and instantly, as if by magic, the proscribed and condemned exile became a powerful, and, as it soon appeared, an all but invincible monarch. This flight from Mecca to Medina [*HEGIRA*] is the epoch from which the Mohammedans date their era. It occurred in the fifty-third year of Mohammed's age, and the thirteenth of his mission, and coincides with July 16 A. D. 622.

Hitherto Mohammed had used only persuasion and argument in propagating his religion. Throughout the eighty-five chapters of the *Koran*, published at Mecca, he exhorts his followers to bear with meekness the injuries to which their principles might expose them, declaring that he had no authority to compel anyone to embrace his creed. In the eighteen chapters published at Medina, on the contrary, he taught a very different doctrine, and announced that God had commanded him to extirpate idolatry by force of arms. The enjoyments of paradise were promised to 'those who fight for the cause of God, whether they be slain or not.' (*Sura*. 11. 4. 9.) Nor were those

MOHAMMEDANISM

mere words of course; they were soon reduced to practice. Mohammed, soon after his arrival in Medina, assumed the exercise both of the sacerdotal and regal office. The option of friendship, or submission, or battle, was proposed to the enemies of Islamism. His petty excursions for the defence or attack of a caravan prepared his troops for the conquest of Arabia. But what established his power, and laid the foundation of future conquests, was the issue of the battle of Bedr, near Medina, fought in the second year of the Hegira, between the troops of Abu Sophian, the new sovereign of Mecca, and his own, in which the latter, though only a third of the number of the enemy, gained a complete victory, with the loss of only forty men. From this period the progress of Mohammed, if not a complete triumph (for he sustained some defeats), affords an example of perhaps the most rapid success on record; and after the lapse of six years, in the eighth Hegira, his victorious troops entered the city of Mecca—an epoch from which may be dated the final establishment of the Mohammedan faith in Arabia. The few contests that followed were merely the last struggles of an expiring opposition, and were mostly terminated by Mohammed's generals; while the prophet himself was employed in destroying the idols enshrined in the Caaba, and in consecrating the temple to the worship of the sole God. The year following is known in Mussulman history as the 'year of embassies;' because missions were sent to the prophet from a majority of the Arabian tribes, giving in their adhesion to his creed; and recognising his authority, both sacred and civil.

But while his religion was thus triumphant, and was destined to spread still farther, the prophet's own days were drawing to a close. About three years before his death his health had been declining, in consequence of poison administered to him by a Jewess of Chaihor, in order to test the validity of his divine knowledge. But his death was occasioned by a fever of fourteen days, on June 6, 632, in the 10th Hegira, in the sixty-third year of his age. His remains were buried in Medina, in the room in which he breathed his last; and though the house itself has long since disappeared, a simple unadorned monument marks the spot where his body reposes. The pilgrim, on his way to Mecca, increases the worth of his pilgrimage if he turn aside to visit also the city which contains the ashes of Mohammed.

During the life of Khadijah, Mohammed did not avail himself of the right of polygamy: after her death, however, the restraints which policy or affection had imposed on him were laid aside, and the utmost license marked his subsequent career. While he limited the number of wives to four in the case of others, he claimed an exemption to himself on divine authority; and married no fewer than seventeen according to some authorities, and nine according to others: strangely enough, all widows except one—

Aysaha, the daughter of Abu Baker. By Khadijah he had four sons, and as many daughters; and by an Egyptian concubine a fifth son; but his sons all died in infancy; and of ten daughters none survived him except Fatima, who was married to her cousin Ali. From this marriage sprang an illustrious offspring; the ancestors of the numerous existing scherifs, or sons of the prophet.

The religion of Mohammed is contained in the *Koran* (i.e. book), the contents of which, according to Mohammedan belief, are uncreated and eternal, subsisting in the essence of the Deity, and inscribed with a pen of light on the table of the everlasting decrees, and communicated at different times by the angel Gabriel. Its author appeals to the beauty of its style as a proof of its inspiration.

The object of Mohammed seems to have been to recal the inhabitants of the populous country of Arabia to a monotheistic worship, and to unite idolaters, Jews, and Christians in the same creed. He taught that the chain of inspiration was prolonged from Adam to the promulgation of the *Koran*; that Christ did not die on the cross, but that a phantom, or a criminal, was substituted in His place, and that He was translated to the seventh heaven; that Christ rejoiced in the assurance of a future prophet more illustrious than Himself; and that the promise of the *Paraclete*, or Holy Ghost, was prefigured in the name, and accomplished in the person, of Mohammed, the last and greatest of the prophets. He taught the existence of angels good and bad, and of the Devil or *Eblis*; describing the latter as having been expelled from heaven, without hope of recovery, for refusing to pay homage to Adam at the divine command. As to the Christian Scriptures, he acknowledged the Pentateuch, the Psalms, and the Gospel. The doctrine of the resurrection and the day of judgment formed part of his faith. He taught that every man shall be judged according to his works; but that the believers in Islamism shall not be subjected (like the wicked idolaters or infidels) to endless tortures, but that, after undergoing a purifying punishment, they shall be translated into the regions of bliss. He inculcated the absolute and unalterable predestination of all things. He called prayer 'the pillow of religion,' and 'the key of Paradise;' and prescribed five different stated periods of prayer daily, accompanied with as many ablutions or purifications of the body. During prayer he first insisted that the face should be turned to Jerusalem, in compliment to the Jews; but afterwards bestowed that honour on Mecca. Alms, fasting, and pilgrimage to Mecca, are the remaining duties of practical religion enjoined on all good Mussulmans. Of the last, the most holy was that of Ramadan, instituted in honour of the month in which Gabriel appeared to him in Mecca. Friday was ordained as the Moslem sabbath, because on that day he made his flight to Medina. He continued the rite of circumcision in compliment to the

prejudices of his countrymen, condemned usury, and forbade the drinking of wine.

The grossly sensual character of Mohammed's paradise constitutes, perhaps, the greatest blemish in his religious system, and has exerted a debasing influence over all the countries where it has acquired an ascendancy.

After his death the rival pretensions of Abu Beker and Ali, the latter of whom called himself 'the first believer,' to succeed Mohammed in the empire he had founded, both gave a temporary check to the progress of the religion, and produced a schism which exists till the present day. [SONNITES; SCHITES.]

Notwithstanding the high pretensions of his competitor, Abu Beker was elected to the office of supreme head of the Mussulman religion and power under the title of *caliph*, or *khalif*, i. e. successor of the prophet. Under his sway, and that of his two immediate successors, the most brilliant victories were achieved by the Arab arms. Indeed, by the 20th Hegira, or within ten years of the death of the prophet, Syria, Persia, and Egypt, being conquered, adopted the new faith. Ali was chosen the fourth khalif, but achieved nothing very memorable. At his death, which took place by the hands of an assassin, the throne was usurped by a son of Abu Sophian, whose descendants are called the Ommiad race of khalifs. They held the sovereignty for nearly 100 years; during which time the whole of Africa was overrun, and so far colonised by tribes of Bedouins that it has since remained, in language, manners, and religion, an Arab country. The Islam faith spread nearly as rapidly in the East; at least within eighty years from Mohammed's death it embraced all the countries between the Indus and the Atlantic, and from the Indian Ocean to the steppes of Central Asia. It has since penetrated even into China, and found its way into many of the islands in the Indian Archipelago. Spain was taken in 711. The Arabs were, for a short time, masters of the South of France, but were finally driven across the Pyrenees in 732. The Ommiad khalifs were, in the 133rd Hegira (A. D. 750), superseded by the descendants of Abbas, one of the uncles of Mohammed. This last dynasty is known in history as that of the Abbasside khalifs.

Meanwhile the seat of the khalifat was removed from Medina to Damascus, and latterly to Bagdad. Nor did the khalifat itself last long. It had been tottering for years; but it fell in the 566th Hegira (A. D. 1258); a Tartar army having taken Bagdad, and put an end to the nominal sacerdotal and regal power of the khalifs, the real power having, for a long time, resided in the Turkish sultans of Asia Minor. The title of khalif is now recognised as one of the attributes of the Turkish sultan as successor of Mohammed, and of the sophi of Persia as successor of Ali; but it no longer implies the discharge of any religious functions.

But neither the foreign conquests of the

Mussulmans, nor the downfall of the khalifat, made any essential change in the political state of Arabia. The people adhere to Mohammedanism as the true faith, but otherwise are divided into petty tribes, and communities, as before the birth of the pretended prophet. Of the two attempts made in Arabia to reform the Moslem faith, all traces of the first (A. D. 809), the object of which was to rescind the prohibition of wine, and to prevent the pilgrimages to the holy ashes, have disappeared. The other took place in more recent times; namely, in the beginning of the last century. It was made by Abdul Waheb, who proclaimed himself a prophet sent by God to reform the abuses which had been gradually engrafted on the religion of Mohammed. The chief of the Wahabee doctrines, so called from their author, was, that God was to be worshipped in the strictest unity; and that no adoration should be paid to Mohammed, or any created being. [WAHABEISM.] But while these doctrines were rapidly spreading, and while the cities of Mecca and Medina had fallen into the hands of the new sect, Mehemet Ali, in the name of the sultan, gave an effectual check (1813) to their farther progress, and restored the holy cities to the nominal authority of the Porte. Since that time the Wahabee tenets have maintained or even increased their influence, even in Nedjed, the native province of the founder. (Abulfeda, in *Vita Mohammed*; D'Herbelot, *Bibliothèque Orient.*; Green's *Life of Mahomet*; the *Travels of Niebuhr* and others; Ockley, *Life of Mohammed*, and *History of the Saracens*; Burckhardt's *Notes on Bedouins and Wahabees*; Rycant's *Present State of the Ottoman Empire*; *Lives of Mohammed* by Boulainvillier and Gagnier; Washington Irving, *Lives of Mahomet and his Successors*; Gibbon's *Roman Empire* ch. l.; Milman, *History of Latin Christianity* b. iv.; Neil's *Mohammed*; Sprenger, *Life of Mohammed*; Mill's *History of Mohammed*; Forster's *Mohammed Unveiled*; Muir's *Life of Mahomet*; *National Review*, July 1858, p. 137; Palgrave's *Journey through Central and Eastern Arabia*; M'Culloch's *Geographical Dictionary*, art. 'Arabia.')

Mohasite. A crystallised titaniferous iron from Dauphiny; named after Professor Mohs, the crystallographer.

Moldore. A Portuguese gold coin, in value 27s. sterling.

Moira (Gr. *a share*). In Greek Mythology, the deity who assigns to every man his lot. [FATES.] The mention of Moera in the plural occurs only once in the Homeric poems (*Il.* xxiv. 29), which speak of Moira generally as spinning, but assign to her no other attributes to distinguish her from Aisa; they further describe her not as an inflexible destiny, but as strictly under the control of Zeus, and influenced to a certain degree by the free will of men. In the Hesiodic *Theogony*, the Moerae have grown into three persons (Clotho, the spinner, Lachesis, the dispenser, and Atropos, the insurmountable), who are described as the daughters of Night. According

MOIRÉE MÉTALLIQUE

to later poets, *Zeus* and all the gods are obliged to submit to their irresistible power. [NOBLS.] **Métallique** (Fr.). Called in this country *crystallised tin-plate*. It presents a variegated and flowered appearance, produced upon the surface of tin-plate by applying to it in a heated state some dilute hydrochloric acid for a few seconds, then washing it with water, drying, and coating it with lacquer. The figures are more or less beautiful and diversified, according to the degree of heat and relative dilution of the acid. This mode of ornamenting tin-plate is much less in vogue now than it was some years ago.

Molars (Lat. *molaris*, *grinders*). Teeth generally having a flattened triturating surface, and situated behind the incisors, and canines, when these are also present. In some Mammals, as the Cape ant-eater, all the teeth are molars. They are generally of two kinds; viz. those which are liable to be displaced and succeeded by others in the vertical direction; and those which are succeeded, and sometimes, as in the elephant and kangaroo, displaced by others developed at the back of the mouth, and advancing forwards horizontally: the first are termed *premolars* or *false molars*, the second true molars.

Molasse. The Swiss name for an extensive middle tertiary or miocene deposit widely spread in Central Europe. It is partly marine, partly fresh-water, and often contains lignite and land vegetation, especially of palm-trees. The molasse is so called as being generally a loose sand, but it varies much in texture and appearance, and not less so in its component parts.

Molasses (Port. *melasses*). A brown viscid uncrystallisable sugar. [SUGAR.] It is sometimes used in England in preparing the coarser sort of preserves, and on the Continent extensively in the manufacture of tobacco. It has a burnt but not a disagreeable taste.

Moldavite. Obsidian of a very dark green colour, from Moldanstein in Bavaria.

Mole (Dutch *mol*, Ger. *maulwurf*). A species of the genus *TALPA* [which see], common in this country and other parts of Europe. This quadruped exhibits in perfection that modification of structure by which the Mammiferous animal is adapted to a subterranean life. Its head is long, conical, and tapering to the snout, which is strengthened by a bone, and by strong gristles worked by powerful muscles. The body is almost cylindrical, thickest behind the head, and gradually diminishing to the tail. There is no outward indication of a neck, that part being enlarged to the size of the chest by the massive muscles which act upon the head and fore-legs. These, which are the principal instruments by which the mole excavates its long and intricate burrows, are the shortest, broadest, and strongest, in proportion to the size of the animal, which are to be met with in the Mammiferous class. The rapidity with which the mole can make its way through a favourable soil is such, that it may be said to swim in the earth; and, since

MOLECULE

it must displace matter so much denser than water, so do its fore-limbs display a mechanism correspondingly superior in strength to the analogous extremities or pectoral fins of the dolphin. The food of the mole consists of worms and insects: its voracity is great, and it soon perishes if food be scarce or wanting. The ardour of the sexual appetite is not less intense and characteristic of this curious quadruped. The sense of sight is very feeble, the eyes being minute and rudimental; but the other faculties of smell and hearing, as being more serviceable in its dark retreat, are extremely acute.

The female prepares a nest of dry herbage, roots, and leaves, in a chamber commonly formed by excavating and enlarging the point of intermission of three or four passages. The young are brought forth, to the number of four or five, in April, and sometimes later.

The farmer views the operations of the mole as destructive to his crops by exposing and destroying their roots, or by overthrowing the plants in the construction of the mole-hills; his burrows, moreover, become the haunts and hiding-places of the field-mouse and other noxious animals. The mole is also accused of carrying off quantities of young corn to form its nest. Hence, every means are devised to capture and destroy it, and men gain a livelihood exclusively by this occupation. Some naturalists, however, plead that the injury which it perpetrates is slight, and that it is more than counterbalanced by the benefit which it produces by turning up and lightening the soil, and especially by its immense destruction of earth worms, and many other noxious animals which inhabit the superficial layer of the ground, and occasion great injury to the roots of grass, corn, and many other plants. The soundest practical conclusion lies probably in the mean of these opinions; and the enlightened agriculturist, while he takes prompt measures to prevent the undue increase of the mole, would do well to reflect on the disadvantages which might follow its total extermination.

MOLS (Ger. *mahl*, Swed. *mål*, a *mark* or *spot*; hence perhaps the English form *iron-mold*: Wedgwood). Different productions of and excretions from the uterus so called by medical writers. Small soft excrescences of the cuticle are also termed *moles*.

MOLÉ (Lat. *mole*, a *mass*). In Engineering, a massive work formed of large stones placed in the sea by means of coffer-dams, extended either in a right line or an arc of a circle before a port, which it serves to close, and to defend the vessels in it from the impetuosity of the waves, &c. It is sometimes used synonymously with *harbour*.

MOLECULE (Lat. *molecula*, dim. of *mole*, a *mass*). This term is frequently misused as synonymous with *atom*. In its strictly chemical sense, however, it means the smallest quantity of an element or of a compound that can exist in the free state. This quantity is, in the case of compounds, sometimes a

MOLINISM

single atom; thus ammonia (NH_3) is both a molecule and an atom. But the molecule of most, probably of all, elements consists of two atoms; and this is also generally the case with so-called compound radicals, which play the part of elements; thus the molecule of hydroxyl (O, H_2) consists of two atoms of O, H . The molecule of ethyl is also double,

Molinism. In Roman Catholic Theology, a system of opinions on the subjects of grace and predestination somewhat resembling those of the Arminian party among Protestants. It derived its name from the Jesuit Louis Molina, professor of theology in the university of Evora in Portugal, who laid down a series of propositions on these debated questions in his work entitled *Liberi arbitrii cum gratia donis, &c., concordia*, which appeared in 1588. He was attacked by the Dominicans on the charge of having advocated in it Pelagian or semi-Pelagian sentiments, and accused before the Inquisition: he appealed to Rome, and the cause was debated for twenty years in the congregations, and left at last undecided by a decree of Paul V. in 1607. Since that period Molinism has been taught as an opinion which believers are free to embrace in Roman Catholic schools, and generally supported by the Jesuit and attacked by the Jansenist party. It must not be confounded with *Molinism*—a name which the doctrine of the Quietists has received from the work of a Spanish enthusiast (Molinos) on *Mystical Life*, condemned in 1687 by Innocent XI. The French Quietists professed to abjure and oppose the errors of Molinos. [**QUIETISTS.**]

Mollesce. [**THEOL.**]

Mollaste. A mineralogical synonym of the crystallised titaniferous iron of Dauphiny.

Mollah. The title of the higher order of judges in the Turkish empire. After the three first magistrates of the empire (the two eadî leshers of Roumi and Anatolia, and the istambol-cadissy or chief ordinary judge of the capital) follow fourteen mollahs, who preside over the fourteen principal seats of justice in the empire; among these, the mollahs of Mecca and Medina have the highest rank. The place of mollah, like all others in the Turkish empire, is held only at the will of the sovereign, and is now granted annually (D'Ohsson, *Tableau de l'Empire Ottoman*, vol. iv.); but displaced mollahs preserve their rank in the Ülema above their successors. The Turkish mollah must not be confounded with the Tartar mulla.

Molluscs or Mollusca. (Lat. from mollis, soft). The name applied by Cuvier to the great primary division of the animal kingdom which includes all species having a gangliated nervous system, with the ganglions or medullary masses dispersed more or less irregularly in different parts of the body, which is soft and inarticulate. The pulmonary or branchial circulation is separate and distinct, but is aided by the direct propulsion of a heart in one class

MOLOCH

only. There is always a heart for the systematic circulation, and it mostly consists of one ventricle and one auricle. Some of the molluscs breathe air, but the greater part respire through the medium of salt or fresh water. The blood of the molluscs is white or bluish. In one class only is there a rudiment of an internal skeleton giving attachment to a part of the muscular system; in the rest it is absent, and the muscles are attached to various points of the skin. Their contractions produce inflexions and extensions of their different parts, and, alternating with relaxations, enable the species to creep, climb, swim, burrow, and seize upon various objects, as the form of these parts may permit; but as the locomotive organs are not supported by articulated and solid levers, the molluscs cannot leap or advance rapidly on dry land. Many of the aquatic species are encumbered with a heavy shell. Nearly all the molluscs have an extensive fold of the skin reflected over their body, which it covers like a mantle; it is sometimes produced into a breathing-pipe, or extended and divided in the form of fins. When the mantle is simply membranous or fleshy, or when a horny or testaceous rudiment of a shell is developed, but remains concealed in the substance of the mantle, the mollusc is said to be *naked*. When the shell is so much enlarged that the contracted animal finds shelter beneath or within it, the species is said to be testaceous. [**CONCHOLOGY.**] The masticatory or oral organs present all the various modifications for predatory, omnivorous, or herbivorous habits; and the stomach may be simple, multiple, or complicated with a peculiar armature.

Some of the molluscs are unisexual, others androgynous, a few dioecious. With few exceptions, their habits and economy present comparatively little variety or interest, and they are only preserved by their fecundity and vital tenacity. [**MALACOLOGY.**]

Moloch. The name of the chief god of the Phœnicians, frequently mentioned in Scripture as the god of the Ammonites. Human sacrifices were offered at the shrine of this divinity; and it was chiefly in the valley of Hinnom, to the east of Jerusalem, that this brutal idolatry was perpetrated. The Topheth (for it is always mentioned with the article) was a place in the east end of this valley, where the children were first killed, and then thrown into the abyss of fire, under an image of Moloch. Solomon built a temple to Moloch upon the Mount of Olives, and Ahas, Manasseh, and other kings imitated his impiety by making their first-born sons pass through the fire kindled in honour of this horrid king. At Carthage, during the invasion of Agathocles, either 200 or 500 children were offered in a single sacrifice to Moloch. (Grote's *History of Greece*, part ii. chapter xcvi.) The word *moloch*, signifying king, occurs commonly in the composition of Hebrew names, as in Melchizedek, Melchishua, &c., and reappears in Milcom, and in Adrammelech, and Anammelech, the gods of Sepharvaim.

MOLOSSUS

The frequency of human sacrifices in Jerusalem is proved by the incessant remonstrances of the prophets, who, upbraiding their countrymen for the shedding of innocent blood, stigmatised Jerusalem as a bloody city.

(Gr. *μολοσός*). In Greek and Latin poetry, a foot consisting of three long syllables, as *ἄσπερ δὲν, regnabant*.

Molybdenite. Native sulphide of molybdenum.

Molybdenum (Gr. *μόλυβδος, lead*). This name was originally applied to the native sulphide of molybdenum, which was considered to be an ore of lead, but was afterwards shown to contain a peculiar metal. Molybdenum is white, brittle, and very difficult of fusion. It forms two oxides and an acid (*molybdic acid*). The compounds of the latter are called *molybdates*. The molybdate of lead has been found native.

Molybdine. Native molybdic acid.

Moment (Lat. *momentum*, from *movere*, to move). Confusion rather than clearness would be the result of an attempt to explain the various significations of this term as used by older writers on mechanics; we shall, therefore, give separately the more modern interpretations of the term in its various combinations.

As applied to *time*, the term *moment* is synonymous with *instant*, and denotes a brief but indefinite period.

Moment of a Couple. The product of either of the two equal and opposite forces, of which the couple consists, into the distance between their lines of action. [COUPLE.]

The *moment of a force with respect to a point* is the product of the force into the distance of the point from its line of action.

The *moment of a force with respect to a plane* is the product of the force into the distance of its point of application from that plane.

The *moment of a force with respect to a line* is found by first resolving the force into two components, one parallel and the other perpendicular to the line, and then taking the product of the latter component into its distance from the line.

Moment of Inertia. [INERTIA, MOMENT OF.]

Moment-axis of a Couple. The finite line which represents, by its magnitude and direction, the moment and *rotation-axis* of a couple. [COUPLE.]

Momental Ellipsoid. [INERTIA, MOMENT OF.]

Momental Plane. In Statics, the plane of the couple which, together with a force of translation, is equivalent to a given system of forces, is called the *momental plane* of the point (*moment-centre*) in which it is intersected by the force. [FORCES, COMPOSITION AND RESOLUTION OF.]

Momentum (Lat.). In Mechanics, denotes the product of the mass of a body into the velocity with which it moves. It is also called the *quantity of motion*.

MONACHISM

(from the Fr. *monerie*, Ang. *munimery*). The name by which certain religionists of the so-called Evangelical party have been designated in Switzerland, and some parts of France and Germany, since 1818. They appear originally to have resembled the Methodists of our own country; for, like the latter, they at first embraced no tenets distinct from those of the established church, and were only distinguished from its members by more frequent religious exercises. But they did not long continue to harmonise with the preachers of the establishment. One of the most vehement of the party, in a pamphlet published in 1818, accused the latter of denying the divinity of our Saviour, and of a thorough backsliding from the doctrines of Calvinism; and the Geneva clergy (*la vénérable compagnie*), having passed a resolution prohibiting any theories on the doctrinal points of religion from being propounded in the pulpit, and having counselled the clergy to avoid disputed points as much as possible in their discourses, the smouldering embers of their hostility burst into a flame. They now began to attack the clergy in the pulpit and in pamphlets. But all their efforts to bring the latter into contempt were unsuccessful: the Genevese remained faithful to their pastors; and in the year 1836 the Momiers possessed only about 200 adherents.

In other parts of Switzerland, however, and more especially in the canton de Vaud, the zeal of these sectaries was attended with more success. After a few years' toleration of their preaching and proselytising, during which it was alleged the Momiers had caused the greatest discord among the inhabitants of the canton, the government at last saw the necessity of interference; and in the year 1824 promulgated some vigorous ordinances to put them down. These enactments, as might have been expected, failed of their effect. The enthusiasm of the Momiers was redoubled: they were now surrounded with the glory of martyrdom; and many who before had viewed their zeal with indifference now sympathised in what they could not but regard as an attack upon the liberty of conscience. In consequence of the general disgust that ensued on their promulgation, these ordinances were at first gradually relaxed, then suffered to lie dormant, and at last repealed in 1831. Since that period the number of the Momiers has gradually diminished; and in 1839 the clergy of this canton resolved by a large majority to revert to the ancient system of the church. (*Edinburgh Review*, vol. xlii.)

Momus (Gr. *μῆμος, derision*). The god of raillery and ridicule, said by Hesiod to have been the progeny of night.

Monachism, Monk, Monastery (all derived from the Gr. *μῆνος, alone*). Words indicative of certain important features in ecclesiastical history. The word *monachus*; or monk, properly signifies one who lives a solitary life, and was applied in the first instance to the

MONACHISM

many persons who began in the second and third centuries to retire from the occupations of the world, and devote themselves in the deserts of Egypt and Syria to a contemplative and religious life. It was not till the middle of the third century that the monkish system, properly so called, was established, by which many persons were congregated together, and bound by vows to the performance of various religious duties. These monks are distinguished by the appellation of *Cenobites*, or *Associates*, from the *ascetics*, *anachorites*, and *hermits*, who lived apart not from the world only, but from each other. The inmates of the primitive monasteries were bound by the profession of four objects: solitude, labour, fasting, and prayers. But although the objects at which they aimed were theoretically the same, the history of monachism was very different in the East and the West, and exhibits commonly a succession of varying phases in each country where it took root. The great type of Western monachism is St. Bernard, that of the Eastern is St. Anthony; but while the monachism of the latter differs little or perhaps not at all from that of the wildest Oriental fakir, the former guided the world to which professedly he did not belong, and wrote from his cell letters of counsel to the vicar of Christ, of rebuke to kings and statesmen, and of warning to the faithful and the unbelieving. The monachism of the East had its origin in that idea of DUALISM which underlies almost every form of Oriental philosophy. It sprang not from any abstract love of solitude, but from a belief in the absolute and hopeless corruption of matter. So far from holding with Christian theologians that material corruption was the effect of moral disobedience, the disciples of Anthony, like those of Buddha [BUDDHISM], looked upon matter as evil, not as having been defiled by a perverted use, but as being in itself the work of an evil god, the principle of defilement to everything associated with it. The Nitrian anchorite fled from society not so much because solitude was necessary, as because only in solitude he could preserve unsullied the treasure of virginity, which seems almost the one idea infused by Christianity into the monastic theory. But the western monks were the members of a society, the soldiers of an army which was to fight the battles of the King of kings; and thus their most prominent characteristic, in contrast with the grovelling asceticism of the East, is power. This power has been one of the greatest props, at one time it may be said to have been the only prop and safeguard of the Papacy. With the rise or degeneracy of the great orders rose or fell the dignity and power of the popes, who with a true instinct took into their special favour the men whom they knew to be the chief bulwarks of their supremacy; and in its turn the character of the popes, or rather of their designs, and the condition of their spiritual empire, exercised a corresponding influence on the monastic orders. While, then, the common asceticism of the learned Benedictine and

of the hermit who gloried in his ignorance connects the theory of Christian monachism in every shape with the remote philosophy of the East, the circumstances of European society soon turned into a different direction the fire which had been kindled by the eloquence of Athanasius. From him came the impulse which sent the descendants of the old *Fabii* and *Claudii* to a life of prayer and penitence at Bethlehem; but while Jerome drew his spiritual colony to Palestine, Ambrose and Martin of Tours were infusing fresh life into the monasticism of the West. The wildest recesses of Gaul were peopled by fervent hermits, who only thought the fare too soft which kept in life the eremites of Egypt. The philosophy of Cassianus drew down suspicion on the convent of St. Victor at Marseilles; while on the heights of Jura Lupicinus rebelled against the light austerities of his brother Romanus. 'Into one cauldron he threw a meal of fish and vegetables which the monks were preparing separately with some neatness and care: and twelve of the brethren left the convent in indignation. "Better were it for thee not to have come here," said Romanus, "than thus to drive away our monks." "It matters not," was his reply; "it is the chaff separating itself from the wheat: God has no portion in them."'

Thus far the growth of Western monachism was rapid but irregular. The abbeys were isolated units with no common centre of action; and if the monks were to carry the world through the dissolution of the old society, it could only be done by their assuming the compact organisation of an army. The crisis was momentous; and it produced St. Benedict. In his wild Nursian retreat he framed a rule for the disciples who thronged to him; and that rule made the act of profession the last exercise of a personal will permitted to the monk, while the perpetuity of the organisation was secured by an absolute and irrevocable renunciation of all property. This form of organisation attracted into the monastic army the first monk who sat on the throne of St. Peter. Thus disciplined, Gregory the Great was enabled practically to seize the prerogatives of the Western emperors, while Maurus issued from Mont-Cassino to carry the Benedictine rule into the North. In Gaul the abbeys of Marmoutier and Condat, and the names of German and Gregory of Tours, of Gall and Columba, attest the activity of the monastic principle in the age of Thierry and Brunehaut, Agilulf, and Clotaire.

But if the monks of the earlier centuries had vastly extended the sway of the papacy, monachism again came to the rescue when its vices seemed to be growing too heavy for the world to bear. The crusades against Albigensians and Waldensians, and the slaughter of Arnold of Brescia for denouncing the unblushing profligacy of the time, would alone suffice to show the gravity of the crisis. Men were gradually becoming tired of the lavish use of fire and sword as the regular arguments to be

MONAD

employed against heretics and unbelievers by priests whose lives were a disgrace to Christianity and humanity alike. In this hour of peril Dominic and Francis came forth to fight with other weapons; and the vow of absolute poverty was added to the vows enjoined by all existing monastic rules. [ORDERS, MENDICANT.] But if the Mendicant order so established became mighty props of the papal empire, they also introduced new sources of weakness. Their very institution was a satire on the secular clergy, and even on the great monastic bodies. The jealousy of faction took the place of former unity; and the celibate secular clergy, the great army of Hildebrand, found their loyalty cooling down, as they were confronted by these professors of a more austere and less worldly system. But the history of the old orders was in the issue repeated in that of the Mendicants. They had forsworn power: they grasped it with greater tenacity than any who had gone before them. Spacious buildings sheltered men who had sworn to live without house or home. They had abjured art and learning; and from their ranks came forth men famed throughout the world for their skill in the former and their attainments in the latter. Over the bones of Francis rose the church of Assisi, rich with gold, azure, and vermillion; and men gazed with devotion on the angelic countenances and placid forms which looked down upon them from walls and tablets, or stood astonished at the science of Thomas Aquinas and Albert the Great.

It is unnecessary to prolong the tale. It has become almost a truism to say that the church and the monastic orders alike exhibit periods of energy followed by ages of sloth, to be succeeded perhaps by an era of renovation. The story of these changes is vividly related by Dean Milman (*Latin Christianity*) and M. de Montalembert (*Les Moines d'Occident*). (*Edinburgh Review*, Jan. 1858, p. 78 &c. and Oct. 1861, art. 'Monks of the West'.)

Monad (Gr. *μονάς*, a unit). In Metaphysics, this word has been used by Leibniz and his followers, partisans of what has been called the Monadic Theory. 'After studying,' says Stewart, 'with all possible diligence, what Leibniz has said of his *monads* in different parts of his works, I find myself quite incompetent to annex any precise idea to the word as he employed it.' He then quotes the following as 'some of his most intelligible attempts to explain his meaning:—'A simple substance has no parts: a compound substance is an aggregate of simple substances, or of *monads*. 'Monads, having no parts, are neither extended, figured, nor divisible. They are the real atoms of nature; in other words, the elements of things.' 'Every monad is a living mirror, representing the universe, according to its particular point of view, and subject to no regular laws, as the universe itself.' 'Every monad with a particular body makes a living substance.' (*Ency. Brit. Preliminary Dissertation*.) The groundwork of the mo-

MONAZITE

nadic theory is to be found in the different philosophical systems of Zeno, Leucippus, Democritus, and Epicurus; but Leibniz was the first who reduced it to a system.

Monadelphous (Gr. *μῆνερ*, and *ἀδελφός*, a brother). In Botany, a term applied to stamens the filaments of which are combined into a single mass, as in the Common Mallow. *Monadelphia* is the name of one of the classes in the Linnæan system.

Monandrous (Gr. *μῆνανδρος*). In Botany, a term applied to a flower having but one stamen. *Monandria* is the name of the first class in the Linnæan system.

Monarchians. In Ecclesiastical History, a name given to a theological party in the third century, which asserted one immutable primary principle in the Godhead, and charged those who could not define the subordination of the Son to the Father as being ditheists or worshippers of two Gods. Their opponents accused them of believing that the Father must have suffered on the cross, and hence branded them also with the name of Patripassians. (Milman's *Latin Christianity*, book i. ch. i.)

Monarchy (Gr. *μοναρχία*, the rule of one). The government of a single person. Monarch and monarchy are equivalent in common speech to king and kingdom; so that we often read of the Spartan monarchs, &c., although the government of Sparta was under a double race of kings reigning at the same time. Monarchies are usually said to be of four kinds—*absolute*, *limited*, *hereditary*, and *elective*, which are self-explanatory terms. The only elective monarchy in Europe was that of Poland. All absolute and limited monarchies have adopted the hereditary principle. [LAWRETT.]

Monas (Gr.). A genus of extremely minute polygastric Infusores.

Monastery (Gr. *μοναστήριον*). The general name for religious houses appropriated to the reception and maintenance of monks and nuns, but especially of the former. For an account of the origin and object of monasteries, see **MONACHISM**, and the authorities there referred to; and for the habits, rules, and peculiarities of the different orders of monks and nuns, see the respective articles, but more especially **ORDERS, RELIGIOUS**. The English term *monastery* was variously rendered by the Greek fathers; thus we find it expressed not only by *μοναστήριον* and *μονή*, but by *εὐμύριον*, a holy place, *μυδρα*, an inclosure, *φορτιστήριον*, a place of meditation, &c. The suppression of monasteries was one of the first consequences of the Reformation in all the countries that abandoned the Popish faith. But even in Roman Catholic states, with the exception of Italy, they have long been on the decline although since the relaxation of the penal laws several monasteries and nunneries have been established in various parts of Great Britain. [MINSTER.]

Monazite (Gr. *μόναζε*, I live alone). A native phosphate of cerium, lanthanum, and thorium, found near Elatoust in the Ural.

MONDAY

Monday. The second day of the week is so called, and means, literally, the *day of the moon*. Its equivalents in French and German are respectively *Lundi* and *Montag*, signifying also *day of the moon*.

Moneta. In Latin Mythology, an epithet by which Juno was described as the protectress of money. The name may perhaps belong to the same root with *MINERVA*.

Money (so called from the temple of Juno *Moneta*, in which money was first coined at Rome). In a previous article, *CURRENCY*, we have called attention to the causes which led all civilized societies into the selection of certain articles as media of exchange, or as representatives of value. These articles are not necessarily metals, for salt, it is said, is used as a medium in Abyssinia; dried cod in Newfoundland; and for ages a small univalve shell, under the name of *cowrie*, has been employed as a medium of exchange in the Indian peninsula. But where metals can be obtained in sufficient plenty for the purpose they have been invariably employed; and among metals, gold, silver, and copper have been almost universally selected, the principal reason for the choice being, that these articles are generally procurable in nearly equal quantities at nearly equal cost, and therefore present, at times not too remote, nearly equal intrinsic or market values; the market value of a commodity, as measured by itself only, being determined entirely by the cost of production. This rule applies in early metallurgy to copper as well as to gold and silver: for of all metals, gold excepted, none is found native so frequently as copper; and gold, though a metal of very wide geological distribution, has not been found, or not been found in any quantity, in those countries which, like ancient Rome and Sweden, originally adopted a copper currency as the basis of their monetary system.

So essential is the adoption of a currency, and, when the choice is given, of a metallic currency, to commercial progress, that we may lay it down as a principle, that just as the development of language is essential to the intellectual growth of a people, so is a medium of exchange essential to civilisation. In fact, no community has ever been capable of reclamation, or of political existence by the side of other men, which fails to adopt, or is incapable of appropriating, a means of exchange. There is, too, a peculiar fitness in the selection of gold and silver. In the first place, gold is generally discovered superficially in a metallic form, and after laborious search, the area over which it is produced being ordinarily limited to the detritus of primitive rocks, or in smaller quantities in the substance of the rocks themselves, from which it must be extracted by great labour. No deep gold mines have, it appears, ever been found. On the other hand, the geological area of silver is much wider. It is less frequently found native, is commonly associated with the ores of other metals, though generally reduced with ease, and is often

MONEY

procured by deep mining. Sir R. Murchison has called attention to this physical relation of the precious metals, and noticed the language of the book of Job as illustrating the different geological sources of gold and silver with exact precision. 'Surely there is a vein for silver'—'the earth hath dust of gold.' (Job xxviii. 1-6.) Hence while sudden accessions have been made from time to time to the quantity of gold in circulation and for employment in the arts, the working of silver mines, and especially the extraction of this metal from argentiferous galena, one of its most prolific sources, has been carried out simultaneously, and to such an extent, as rapidly to counterpoise any disturbance of the mutual values of gold and silver. For although there is not and never can be any precise ratio of intrinsic value possessed by each of the two precious metals, yet, in modern times at least, the margin of oscillation is so narrow, that with due precautions both may be used simultaneously as media of exchange, the one for large, the other for small values. The double or triple circulation of the metals gold and silver, or gold, silver, and copper, may be effected by adopting the rule employed in this country, of taking one among these metals, either gold or silver, as the commodity in which values are expressed and obligations created, and by bestowing on the other metals, when put into circulation, a larger value than that which they naturally possess or could possess, and depriving them of what is technically called the privilege of legal tender, that is the being presented compulsorily in liquidation of a debt.

Besides the quality essential to the function of a means of exchange, that of its being produced in nearly equal quantities at nearly equal cost, the precious metals have other characteristics second in importance only to that which has been already named. They are comparatively speaking indestructible, and therefore can be at once treasured up for an indefinite period, and by transfer from hand to hand are capable of effecting an indefinite number of exchanges. No perishable commodity could form a monetary unit; the acceptance of money being founded on the condition that the recipient can at a future period employ it for as many, or nearly as many, commodities as he could have obtained with it when he first accepted it in satisfaction of an obligation. The fundamental characteristic of money would be lost, if it were liable to spontaneous alteration, waste, or decomposition. Again, it must be homogeneous, or of equal value throughout its whole substance. Next, it must be easily susceptible of division and reunion. Precious stones might for certain purposes be made media of exchange, possessing as they do high value in small compass, and therefore the characteristic of easy transport from place to place. But the mass of gold or silver may be divided into small portions, and so be made available for small transactions; and as these portions may be readily reunited by fusion,

MONEY

with no loss in the process beyond that involved in the labour which had previously divided the mass or ingot, the aggregate of small pieces is of no less and of no greater value than the original and undivided quantity. Now as many articles of value do not possess these qualities at all, and as none possess them all, it is no wonder that, since a medium of exchange in order to be perfect requires all these characteristics, all societies have, spontaneously and as if by instinct, adopted the precious metals as their money.

It is generally taken for granted, that in early ages the practice of paying in money by weight is a proof that coins in the strict sense of metallic masses of certified weight and purity were unknown. It is difficult to see, however, how mere masses of bullion could have answered the purpose of payment at all, except as a kind of barter, of a more difficult and precarious character than barter in any other commodity. It cannot, indeed, be asserted that coinage and a metallic currency were contemporaneous; but the mere practice of weighing money is no proof that a coinage did not exist, since the acceptance of money by tale indicates not only confidence in the authority by which it was first issued, but trust in the integrity of the person from whose hands it is received; and it is perfectly certain that the habit of weighing sums of coined money continued for ages after it is notorious that coined masses were issued. Nor is it remarkable that writers have assigned the invention of a coinage to certain definite persons, as to Pheidon in Argos, Darius in Persia, and the like. In ancient history, and, indeed, in modern history too, the disposition to identify a practice with a particular date and a particular individual is so strong, that statements to such an effect are readily made and as unhesitatingly accepted. Of one thing we may be quite sure, that the greater part of the advantages of a metallic currency, or money proper, are lost in the absence of a coinage, and that when the precious metals were first adopted as a means of exchange no long time could have elapsed before the obvious and essential advantages of a coinage were recognised and adopted. It is probable that the use of the precious metals for purposes of exchange had a beginning in historical times; but it is very improbable that the practice should have been adopted, and yet that for centuries nations should have been content with so rude a system of exchange as bartering quantities of commodities for rude ingots, and failed to see the advantage of a coined currency. Nor is the negative argument of the absence of early specimens of coins of any vital significance, unless we conclude that the habit of hoarding and hiding specie is of universal force.

A coined piece of money is a mass of metal issued by an authority which gives a practical guarantee of its weight and fineness. As we have observed, the latter is of greater import-

ance than the former, the practice of weighing the precious metal, even when coined, having long survived after coinage had been familiar to society. But the security given in a coin, that the fineness of the metal is according to an intelligible standard, is so important, and the policy of keeping that standard unchanged of such paramount prudence, that, however much governments have tampered with the weight of the nominal quantity, they have seldom, unless thoroughly demoralised and desperate, ventured on altering or debasing the standard; and when they have done so, the result has been in the last degree ruinous. For although it may be true that after all a coin differs in name and designation only from a mass of bullion, and the barter of commodities for coins is ultimately only an act of simple exchange, yet the coin, if it be issued by a sufficient authority, is effectually a manufactured commodity, the market value of which for the time being is precisely known and generally intelligible, and which owes the readiness of its acceptance to the fact of its being manufactured and appreciable by common understanding.

Hence, in order to obviate the endless confusion and inconvenience that could not fail to arise if individuals were permitted to coin money, from the circulation of coins of all weights and degrees of purity, the government of every civilised country has generally prohibited the issue of coins by private parties, and has itself supplied those in circulation. In accordance with the same policy severe penalties have been inflicted on the forgers of coin, or on those who fabricate counterfeit coins, or coins of less weight than the standard, or made up in whole or in part of some baser or less valuable metal. It is found, however, that the improvement of the fabric of the coins, by the perfecting of the dies and otherwise, is a more effectual means than even the utmost severity of punishment for the prevention of forgery.

Where the use of coins has once been adopted, all values in contracts and other engagements are rated or estimated in money; and it is usual in almost all countries to enact that coins of the legal or standard weight and purity shall be *legal tender*, and to declare that no legal proceedings of any kind shall be instituted on account of any debt or pecuniary obligation against any individual who has offered to liquidate the same by payment of an equivalent amount of the recognised coin of the country. A pound troy, or 12 oz. of the metal of which English silver coins are made, contains 11 oz. 2 dwts. pure silver, and 18 dwts. alloy. This pound is coined into 66 shillings; so that each shilling contains 81.09 grains fine silver, and 87.43 grains standard silver; and the money pound, consisting of 20 shillings, contains 1618.69 grains pure silver, and 1748.6 grains standard silver. From 1600 down to 1816, the pound weight of standard silver bullion was coined into 62 shillings. All the English silver coins have been coined out of

MONEY

silver of 11 oz. 2 dwts. fine, from the Conquest to this moment, except for the short period of sixteen years from the 34th Henry VIII. to the 2nd Elizabeth.

The fineness of gold is estimated by carat grains equivalent to $2\frac{1}{2}$ dwts. troy; gold of the highest degree of fineness, or pure, being said to be 24 carats fine. The purity of our present gold coins is 11 parts fine gold or one part alloy. The sovereign, or twenty-shilling piece, contains 113·001 grains fine gold, or 123·274 grains standard gold. The pound troy of standard gold is coined into 46 sovereigns and $\frac{139}{100}$ ths of a sovereign, or into 46*l.* 1*s.* 6*d.* The Mint or standard price of gold is therefore said to be 46*l.* 1*s.* 6*d.* per pound troy, or 3*l.* 17*s.* 10*d.* an ounce. The alloy in coins is reckoned of no value; it is allowed in order to save the trouble and expense that would be incurred in refining the metals to their highest degree of purity, and because when its quantity is small it renders the coins harder, and less liable to be worn or rubbed. Were the quantity of alloy considerable, it would lessen the splendour and ductility of the metals, and would add too much to the weight of the coins.

The unit of money accounts in all countries seems to be arbitrary and artificial. In Greece, it was the drachma, a silver coin; in Rome, the as, a copper coin. No rational interpretation has been given of this selection, and indeed the weight of the drachma of Greece varied in the Doric and Ionic races. The mina and talent, moneys of account, appear to have been derived from the Eastern world.

In Western Europe, the pound, libra, a weight apparently of Sicilian origin, was almost universally adopted, though the weights assigned to this quantity exhibit considerable variations. It is hardly necessary to say that the pound of silver was never coined in mass, but was only, like the Greek talent and mina, a money of account.

The English system attempted in some degree to unite the traditional pound with a natural system of weights. The pennyweight was defined by law to be 32 grains of wheat taken from the middle of the ear. Mr. Norris (*Phil. Trans.* 1776) subjected this rude estimate to a practical test. He weighed 96 grains of wheat of the harvest of 1773, and found that 32 of them taken at random weighed 22·5 grains troy, and 240 such pennyweights were equal to 6,400 grains troy, the weight of the Saxon pound, which stood to the troy pound in the proportion of 540 to 576, and to the avoirdupois pound in that of 54 to 70. The troy pound was substituted for the Saxon pound by Henry VII.

The moneys of various European countries have been degraded at various successive epochs. The degradations of the English mint will be found in the table given below. The Scotch currency had fallen at the time of the Restoration to a thirty-sixth of its original value; the English to a third. The French, whose franc or livre is the shrunken substitute of the

ancient pound, contains little more than a seventy-fifth of the original quantity. It appears that the degradation has been carried still further in some parts of the Continent. The separate coinage of Scotland ceased at the Union; that of Ireland, in which kingdom the gold and silver coins were nominally rated $8\frac{1}{2}$ higher than their English equivalents, was made identical with the currency of the United Kingdom by the Act 8 Geo. IV. c. 79. It is hardly necessary to say, that so barbarous a system as that of a different currency in three states forming for political purposes a single community ought not to have been retained an instant after the union was effected.

It is generally supposed, that the successive degradations of the monetary unit were the expedients of bankrupt and dishonest governments, who practised on the ignorance of communities, by abstracting a portion of the customary quantity of silver from their new issues, and were thus able by successive diminutions to reduce the metallic value to one-third of its original weight. But it may be doubted that the community was ever so ignorant as to be taken in by so transparent a fraud, or that any government was ever so suicidal as to cripple its future resources for the sake of temporary and slight relief. In all likelihood payments were made by weight, the impress on the coin having no further necessary significance than a pledge of the fineness of the standard. It is, indeed, only on the presumption that accounts in specie were really kept by weight, that we can explain those facts of the fifteenth century which caused so great a difficulty to Adam Smith—the low price of corn, the apparent degradation of the currency by 25 per cent., and the high price of labour. Nor is it likely that the parliament which took so independent a position in the fifteenth century, would have been silent during these successive frauds, when it dwelt with so much freedom on acts of the crown of far less importance; nor that the crown, a large portion of whose revenues was derived from fixed rents, fines, and reliefs, should have met a temporary difficulty by a permanent loss; especially as the new issue would, on the hypothesis of its circulating at the same nominal value as the old, have banished the latter from sight, and have been necessarily received in payment of taxes. We may be quite certain, that there is nothing which is so rapidly, so clearly, and so effectually understood, as any fraudulent issue of a light currency.

The debasement of the currency, that is the issue of base money, has been occasionally practised by governments. Its consequences are in the highest degree and immediately disastrous. Much of the misery which befell France during the fourteenth century was ascribed to this pernicious practice, for at the time the great peers of France possessed the right of coining money, and both monarch and grandes debased the currency without scruple. In

MONEY

England the worst effects followed from the adoption of this expedient by Henry the Eighth and the Protector Somerset. It is probable that no act of government in this country ever produced such wide-spread distress as the gigantic debasement committed by Henry the Eighth. It is certain that there was never in those evil times so gross a deed of monstrous and insolent tyranny. The first subjoined table will inform the reader of the extent to which the debasement was carried. This spurious money was called in by Elizabeth, was purchased compulsorily at even less than its intrinsic value, and fell little short in nominal amount of three-quarters of a million. The modern system of English money dates from the restoration of the currency at the commencement of Elizabeth's reign.

When gold and silver are equally a legal tender, i.e. when the proffer of either in liquidation of debts is a bar to action, it is necessary that their mutual value should be fixed by government; and payment in either should be determined by a fixed proportion. Attempts were made, though without success, to fix such a proportion from the earliest times in which gold has been coined in this country, though finally the regulations have been so far effectual as to induce the substitution of gold for silver as a legal tender or as a standard of value. [CURRENCY, DOUBLE.]

In England the over-valued metal was gold, and apparently the proportion fixed became progressively more unfavourable to silver. Hence the substitution of gold for silver in all large payments, and ultimately its sole recognition as a standard.

In France the reverse error was committed. Silver was over-valued, and in consequence gold disappeared from circulation. But as the proportion established by law remains unaltered, and the option of payment in either metal is still left to the debtor, the large accessions of gold to the circulating medium by the discovery of mines in California and Australia have reversed the phenomenon, and silver is rapidly disappearing from France. Considerable attention has been called to this fact by the publication of a treatise on the gold discoveries, from the pen of M. Michel Chevalier. This work was translated into English by the late Mr. Cobden. It appears, however, that, although the evils of a double currency exist and are very significant, the fears expressed by the author are exaggerated. It is almost impossible to decide on abstract grounds which of the two precious metals is the fittest for a standard of value. Neither seems to possess so marked an advantage over the other as to suggest the abandonment of that metal which has been hitherto habitually used. In this country it needs not to be observed that gold is the standard, silver being purposely over-valued by $6\frac{1}{2}$ per cent. and limited as a legal tender to amounts of forty shillings and under; while copper is over-valued by 50 to 70 per cent. and similarly limited to payments of

twelve pence. These regulations were established at the restoration of cash payments, 56 Geo. III. c. 68.

No seigniorage or duty has been levied in this country on the legal standard, since the commencement of the seventeenth century. There is no necessary objection to a slight duty on coined money, the weight of the coin being reduced by the amount of the duty. A coin is a manufactured article, manufactured indeed for obvious reasons by government, but, by reason of the labour employed upon it, a more valuable commodity than an unstamped and uncertified piece of bullion. Hence as a sovereign is of exactly the same value as its weight in gold of the same fineness, there is nothing to prevent the melting of coin, for purposes of exportation, beyond the trouble of fusion. As, however, in effect, English sovereigns circulate in many parts of the Continent, and are even received as legal tender, it may be doubted whether the melting of English gold coins is carried on to any notable extent. A seigniorage, however, is virtually levied on the silver and copper currency, and amounts to so considerable a sum as to defray the ordinary expenses of the Mint. But a seigniorage on gold coins is levied in France, and the weight of the napoleon is reduced by an equal amount below its nominal value. Hence the French gold currency does not, like the English, answer all the purposes of bullion in a manufactured and certified form.

Since the reformation of the currency in 1816, the statutes prohibiting the export and import of gold and silver coins have been repealed, and transactions in the currency of this and other countries are not only permitted but unregistered. The only possible inconvenience which might be supposed to ensue from the abolition of these restrictions is contained in the supposed ignorance of the amount of specie imported into the country. But even if knowledge on this subject were of any great importance, it is supplied indirectly by the fact, that owing to the perfection of our banking institutions, the greatest amount of all imported specie passes through the bank of England, and is by means of this institution distributed over the world. It is of great, indeed of vital importance, to the monetary system of the country, that accurate knowledge should be possessed of the amount of specie held by the great centre of English commerce, the bank of England; but unless the public were also acquainted with the amount of specie held by the general community, the mere facts of the import and export of bullion could have little more than a scientific or speculative value. It is enough to know the causes which determine the influx and efflux of bullion.

Notice has been already taken of the substitution of metallic currency or money proper under the head CURRENCY, to which the reader may be referred. Care, however, must be

MONEY

taken to distinguish bank paper convertible at the pleasure of the holder, from paper money in the sense of an inconvertible paper issued at the pleasure of government, and not exchanged at the pleasure of the holder into specie. The effects of the latter form of paper substitute are analogous to those which ensue from an issue of a debased metallic currency; with this difference, indeed, that unless the inconvertible paper, so issued, descends, as it too frequently does, to notes of low denomination, the parties who are made subject to the effect of such a paper are better able to understand the depreciation of the security, and to bear the loss. When, however, the metallic currency is debased, the loss for the most part falls on those who live by wages, whose hard earnings are mulcted by a fraudulent issue, and whose inexperience is incompetent to deal with the wrong committed.

The second table annexed to this article contains an account of moneys actually coined and still current in Europe, and in some

places beyond its limits. Some change has been effected in certain German states, to be treated hereafter. Continental countries are rapidly approximating to the use of a common measure; for instance, in adopting the franc through Western Europe, and the thaler over the eastern bank of the Rhine. Such a tendency is not only natural, but highly desirable, for there can be no doubt that the operations of business would be exceedingly simplified, international communication would be made more complete, the maintenance of peace in the world would gain additional strength, and the fluctuations in the rate of exchange be reduced to the narrowest margin, if it could be possible to establish a uniform standard and a uniform currency. The barbarism, too, of a plurality of money measures in communities where commercial relations are daily becoming more intimate, is of comparatively modern origin, for some centuries ago the interpretation of rates of exchange was easy and obvious.

I. ENGLISH COINS.—Account of the English Silver and Gold Coins; showing their Value, the Seigniorage or Profit upon the Coinage, and the Price of the Pound Troy of Standard Gold and Silver, from the Conquest to the Present Time.

Moneyers, Company of. Certain officers of the Mint were thus designated, under whose superintendence and responsibility the various moneys of the realm were manufactured. In the year 1837 the government contracts with this company ceased, and their duties were transferred to other officers under the more immediate appointment of the Master of the Mint. The details of these changes, and of the duties of the moneyers as contractors for the manufacture of the money of the realm, will be found in the Parliamentary Reports relating to the Mint, published in 1837. [MINT.]

Mongolfier Balloon. A balloon filled with atmospheric air considerably dilated by heat, so called from its inventor. A fire-balloon.

MONOCHROME

Moniliform (Lat. monile, a necklace). A Botanical term: it is applied to the pod of the *Hedysarum moniliferum*, from its necklace-like appearance.

Menisaceae (Monimia, one of the genera). An order of diclinous Exogens, of the Menispermatal alliance, consisting of aromatic trees or shrubs, with opposite leaves. They are found mostly in the forests of South America. The order is distinguished by its perigynous stamens, its pendulous seeds, and its small embryo on the outside of copious fleshy albumen.

Monisia (after M. Monis, a botanist of Madeira). A subarborescent genus of *Umbelliferae* found on the island of Deserta Grande, one of the Madeira group, where it is called the *Carrot-tree*. It has a crooked woody stem, one to four feet high, gouty at the base, terminating in a tuft of decomposed broadly triangular fern-like leaves one to three feet long, and small white flowers disposed in compound many-rayed umbels. The orchilgatherers and fishermen, who resort to the island, eat the roots when prevented by weather from getting better food. These roots have long curved horn-like divisions, black outside, farinaceous and white within, and much more fibrous than those of a carrot.

Monkeypot. A name given to the woody pericarp of *Lecythis ollaria*.

Monkshead. The *Aconitum Napellus* of botanists. [ACONITE.]

Monocarpous (Gr. *mónos*, single; *καρπός*, fruit). In Botany, a term invented by De Candolle to designate what gardeners call annual plants, and a few others which, like the American aloe, although they may live for many years, yet perish as soon as they have once borne fruit.

Monochlamydeous (Gr. *mónos*; *χλαμύς*, a cloak). In Botany, applied to those plants which have but one floral envelope.

Monochord (Gr. *μονόχορδος*, with one string). In Music, an instrument consisting of a single string stretched between two bridges standing on a graduated rule, for the purpose of measuring the variety and proportion of musical sounds. The monochord is called the *harmonical canon*, or the canonical rule.

Monochromatic Lamp. When a solution of common salt is added to spirit of wine, the mixture burns with a flame in which yellow predominates almost to the exclusion of the other coloured rays; the consequence is, that objects viewed by this light are all either yellow or black, and deficient in the tints which they exhibit when seen by solar light, or by that of our ordinary combustibles. (Sir David Brewster, *Family Library*, on 'Natural Magic'.)

Monochrome (Gr. *μονόχρωμος*, of one colour). A painting executed in a single colour, but relieved by light and shade. A drawing in chiaro-scuro is a monochrome, whether in black and white or in any colour and white.

MONOCOTYLEDONS

Many of the ancient painters were monochromists, as for instance Zeuxis: the skia-gram or silhouette is not a monochrome, though executed in a single colour. [PAINTING.]

Monocotyledons (Gr. *μόνος*, and *κοτυλήδων*, a cavity). A class of plants having but one cotyledon or seed-lobe in the embryo. They are now more generally called **ENDOGENS** [which see].

Monodelphs (Gr. *μόνος*, and *δελφύς*, a womb). A name given by De Blainville to the first sub-class in his binary division of Mammalia, comprehending those which have no supplementary external pouch or marsupium, but which bring forth the young in a state sufficiently mature not to require such additional protection. It is antithetical to Didelphs.

Monodon (Gr. *μόνους*, one-toothed). The generic name of the narwhal, signifying its supposed peculiarity of having but one tooth, which projects like a horn from the fore-part of the head; a second tooth, however, is always to be found concealed in the adjoining jaw, where it remains in a rudimental state. In the female both tusks are rudimental.

Monody (Gr. *μονῳδία*, a solo). A species of poem of a mournful character, in which a single mourner is supposed to bewail himself: thus distinguished from those pastoral elegies (like the *Daphnis* of Virgil) which are in the form of dialogues.

Monœcia (Gr. *μόνος*; *οἶκος*, a house). In Botany, the twenty-first class in the system of Linnaeus, comprising the Androgynous plants, or those whose structure is both male and female. Thus *monœcious* means having both male and female flowers on the same plant, but separate.

Monogenesis (Gr. *μόνος*; *γένεσις*, birth). Professor van Beneden understands this term as applied to the direct development e.g. of an Entozoon from a parent resembling itself. Prof. A. Thomson uses it as applied to descent of an individual from one parent form, containing both the sperm cell and germ cell, or male and female parent principles.

Monogram (Gr. *μόνος*, and *γράμμα*, letter, or writing). An abbreviation of a name by means of a cipher composed of two or more letters intertwined with each other. Monograms were used on coins in very ancient times, being found on Greek medals of the age of Philip and Alexander of Macedon. The Greek monogram of the name of Christ, which resembles P placed perpendicularly in the middle of an X, thus **Χ**, is found on coins of the age of Constantine. By far the greater number of the ancient monograms are still unintelligible. Among others whose researches on the ancient monograms may be consulted with advantage are: Montfaucon, *Palæographia Græca*; Froelich, *Annal. Reg. Syr.*; Combe, *Museum Hunterianum*; Torremuzza, *Description des Monnaies de Sicile*; Pellerin, *Recueil des Villes des Peuples, et des Rois*; Mionnet, *Traité d*

MONOLITH

la Numismatique. Monograms are frequently found on coins and maps of the middle ages; and they are also to be met with as a substitute for the signature of the princes of that period. This class of monograms is of great importance, and their investigation constitutes a distinct and peculiar branch of diplomatics. In later times monograms were frequently employed by printers and engravers to record their names at the end or on the title-page of a book, or in some portion of an engraving. The Abbé de Marolles, in 1667, was the first who directed attention to this branch of the subject; and to him succeeded Florent Lecomte (*Cabinet des Singularités d'Architecture*, &c.); Orlandi (*Abecedario Pittorico*); Fr. Chrüt (*Anzeige und Auslegung der Monogrammatum*); De Virloy (*Dictionnaire d'Architecture*); and Bartsch (*Peintregraveur*, a work of great accuracy and research). But the most complete and accurate information on this class of monograms is to be found in the editio optima of Brulliot (*Dictionnaire des Monogrammes*, &c., avec lesquels les Peintres, &c., ont désigné leurs Noms, 2 tom. 4to. Munich 1832; a work founded on the principle of considering the first letter of the monogram as the key to its explanation).

Monograph (Gr. *μόνος*, and *γράφω*, I write). A treatise or memoir on a single subject, as, for example, the greater part of the memoirs which are read before learned societies.

Monogynia (Gr. *μόνος*, and *γυνή*, a female). In Botany, the name given by Linnaeus in his system to the first order or subdivision in each of the first thirteen classes of plants, comprising such as have one pistil or stigma only in a flower. Thus *monogynous* means having but one style or stigma.

Monoid (Gr. *μονοειδής*, of one form). A name given by Prof. Cayley (*Proc. of British Association*, 1862) to a surface which possesses a conical point of the highest ($n-1$)th possible order. Such a surface is represented by the equation $Q\omega = P$, where P and Q are homogeneous functions of x, y, z of the orders n and $n-1$ respectively, and $\omega = 0$ is the equation of a plane. The origin is the conical point, or vertex. The cones P and Q are called respectively the *superior* and *inferior cones* of the monoid. Such surfaces are of use in the investigation and representation of curves in space. The hyperboloid of one sheet is a familiar instance of a monoid.

Monolith (Gr. *μόνολιθος*, of one stone). A term recently introduced into England, to signify a pillar consisting of a single stone. Herodotus speaks of a huge rock of this sort in front of a temple at Saïs, which was scooped out, and contained an apartment eighteen cubits in length, twelve in breadth, and five in height. It was said to have been transported from the town of Elephantine by order of king Amasis, and to have occupied 3,000 men for three years in conveying it. Some remarkable monoliths have been found in Egypt; of these the zodiac of Denderah, and the obelisk

MONOLOGUE

of Luxor, both of which have been removed to Paris, are well-known examples.

Monologue (Gr. *μόνος*, and *λόγος*, a discourse). A speech uttered by one of the dramatic personae of a play when alone, or, as it is vulgarly termed, speaking to himself. In the drama of ancient Greece soliloquies are rare; for the passages at the commencement, or *prologues* of plays, where the first actor comes forward and explains his own character and something of the subject of the piece to the audience, can hardly be termed soliloquies. The speech of Ajax before his death, in the play of *Sophocles*, is a celebrated exception.

Monomania (Gr. *μόνος*, and *μαίνομαι*, I rage). Insanity upon one particular subject, the mind being in an apparently sound state in reference to other matters.

Monome or **Monomial** (Gr. *μόνος*, and *μέτρος*, a portion). In Algebra, an expression consisting of a single term. It may or may not contain more than one factor. Thus a , $2ab$, $3ac^2$ are monomials.

Monomerans (Gr. *μόνος*, and *μυρρίς*, a limb). A section of Coleopterous insects, including those in which the tarsi were supposed to be formed of a single joint.

Monomyaria (Gr. *μόνος*, and *μύς*, muscle). Bivalves or conchifers, which have only one adductor muscle, and consequently but one muscular impression on each valve.

Monomourans (Gr. *μόνος*, and *νεῖρον*, nerve). A term applied by Rudolphi to the series or primary division comprehending the animals which he believed to have only the ganglionic system of nerves, as the molluscs and insects.

Monopetalous (Gr. *μόνος*, and *πέταλον*, a petal). In Botany, a term applied to a corolla the petals of which cohere by their contiguous margins, so as to form a tube.

Monophyllous (Gr. *μόνος*, and *φύλλον*, one-leaved). In Botany, a term applied to a calyx the sepals of which cohere by their contiguous edges into a kind of tube or cup. It also denotes anything which has only one leaf.

Monophyodonts (Gr. *μόνος*; *φύς*, I generate; *ὀδούς*, tooth). In Zoology, those mammals which generate one set of teeth, as e.g. the sloths, armadillos, orycteropus, ornithorhynchus, and the true cetaceæ; all other mammals that have teeth generate two sets, called *deciduous* and *permanent*.

Monophysites (Gr. *μονοφυσίται*, from *μόνος*, and *φύσις*, nature). A name given in the fifth century to certain heretics who, in the language of the Athanasian creed, 'confounded the substance,' that is, the divine and human substance, which are united in Christ, but neither absorbed into the other. [INCARNATION; EUTYCHIAN; NESTORIAN.]

Monopleurobranchians (Gr. *μονόπλευρος*, with one side, and *βράγχια*, gills). A name given by De Blainville to an order of his class *Paracephalophora*, comprehending those species which leave the branchiæ more or less com-

MONOPOLY

pletely covered by a part of the mantle, and situated on the right side of the body.

Monopoly (Gr. *μονοπωλία*, from *μόνος*, alone, and *πωλία*, I sell). In the history of English commerce, we shall find that the natural freedom of trade has been greatly interfered with by regulations which, originally enacted as measures of police, or for public defence, have been made, as a portion of the royal or parliamentary prerogative, a source of income to the crown, or of pecuniary advantage to the favourites of a dominant party in the legislature. It is clear that there is a natural right to free exchange, and that any interference with the fundamental privilege of individual action (that, namely, of disposing according to the best of a man's discretion of his personal labour or its products) can be defended only on those grounds of public policy which on any interpretation of the theory of government must override private interest circumstances, in cases where the latter is wholly irreconcilable with the former. It is hardly necessary to observe, that such a clashing of interests is very rarely of other than obvious solution.

In early times the police exercised over craftsmen and traders in towns, and by implication over the apprenticeship of the former and the registration of the latter in a guild or fraternity, stood in the place of that modern method of municipal government which is not less effective than the ancient régime, and far less obstructive in its incidence. The apprenticeship of the artisan and the registration of the trader was a pledge of good conduct, and as the privilege in either case was to some extent a reversal of the feudal system of dependence, the aid of the crown was invoked in order to create and confirm the privileges of the borough towns. As a natural consequence, the right of sole labour and sole sale, which the town achieved as a protection from feudal lords, and the crown sustained as a barrier against feudal insolence or independence, degenerated, when the motive for the institution was abolished, into a narrow monopoly on the one side, and a lucrative prerogative on the other. The first age of monopoly was the monopoly of chartered towns, and their analogues, the great privileged markets or fairs.

This ancient prerogative of the crown was after the Reformation, when society was wholly revolutionised, exercised in favour of individuals. Towards the close of Elizabeth's reign, the grant of monopolies to private traders had become so general, and withal so intolerable, as to provoke angry comments in the House of Commons, where in particular one of the members enquired whether bread had not been made subject to monopoly. These private monopolies were declared illegal at the conclusion of the reign of James I. But in the end the powers claimed by the crown were usurped by parliament.

Charters conferring special rights and sole privileges of trade on companies have their beginning at about the same date with private

MONOPOLY

monopolies, but after the Revolution they were conferred in important cases very freely by parliament. There was indeed this defence for the action of the legislature, that some of these corporations of traders, as, for instance, the Bank of England and the South Sea Company, did considerable public service in negotiating loans, and in securing lower terms for the purchase of public stock than could perhaps have been procured by general subscription. But, as we have learnt since the privileges of these great companies have been invaded or annulled, the effect of the restriction has been exceedingly detrimental to the growth of public wealth. Had not the monopoly of the bank of England been invaded, the benefits of joint-stock banking could not possibly have been afforded to the community; and, still more markedly, if the sole privilege of trade in the East, secured by its older charters to the East India Company, had not been annulled, the vast and flourishing commerce with the regions lying beyond the Cape would have been represented by the languid and unprofitable transactions of the incorporated merchants of Leadenhall Street. All the energy which is now peopling Australasia with the Anglo-Saxon race, would have been lost or rendered abortive if the old monopoly of the Company had been retained.

A fourth phase of monopoly was that which characterised the colonial system. In order to secure the fancied benefits of a sole trade, the government of this country, in return for a rigid system of an exclusive market for its own produce, secured the colonists the questionable boon of imperial protection, and reciprocated their own exclusive right of traffic by prohibiting or visiting with enormous duties the importation of raw produce from independent states, provided the same commodities formed a part of colonial industry. Hence the differential duties on sugar, coffee, timber, &c. It is manifest that under such circumstances the colony and the mother country were equally losers. Both paid higher prices, or, what is the same thing, expended more labour for inferior articles. The merit of refuting theoretically the absurdities of the colonial system must be assigned to Adam Smith; the practical explosion of the reciprocity scheme was found in the immense impulse given to trade by the independence of the American plantations, notwithstanding the gloomy predictions of commercial men with which the commencement of that epoch was accompanied.

In modern language, the term *monopoly* is used somewhat loosely for such special advantages as are assigned or supposed to be assigned to particular interests in the community, and which are held up to odium under the name of class legislation. This is not the place in which any discussion on the nature or the number of such privileges can be fitly introduced; but in general it may be laid down as an economical axiom, that every invasion of absolute freedom in acts of exchange is perpetually open to assault, and can only be defended on the high-

MONOTHEISM

est grounds of public policy; and that it is equally certain, that the advantage given to particular interests is only apparent, and tends by a just law of retribution to the ultimate injury of the favoured class, just as it is assuredly an inexcusable wrong to the general public.

Monopolylogue (Gr. *μόνος*; *πολύς*, many; and *λόγος*, a discourse). A term recently invented to designate an entertainment in which a single actor sustains many characters.

Monopteral (Gr. *μονόπτερον*, with but one wing). In Architecture, a temple, or circular enclosure of columns, without a cell.

Monorhyme. A composition in verse, in which all the lines end with the same rhyme. This species of composition is said to owe its invention to Benin, who wrote in Latin, and dedicated his monorhymes to Pope Alexander III.

Monosepalous. In Botany, having the sepals all united into one body by their edges.

Monostoma (Gr. *μόνῳστόμα*, with one mouth). The name of a genus of Trematode Entozoa, including those which have only a single pore, serving at once for nutrition and adhesion.

Monothalamans (Gr. *μόνος*, and *θάλαμος*, a chamber). This term is applied to those univalve shells which have only one chamber.

Monothelism (Gr. *μόνος*, and *θεός*, God). The belief in the existence of one God, in contradistinction to polytheism, the belief in many gods. The attempt to ascertain the extent or the origin of such a belief must carry us into an examination not only of historical and other documents, but also of human language. If it be the fact that all names or words which now bear an abstruse signification 'had their first rise from sensible ideas,' that words which now denote the Divine Spirit meant originally nothing more than the breath of the sky; if it be true, as Professor Max Müller holds, that the establishment of human relationships succeeded the dawn of a knowledge of numbers, and preceded the conception of a Creator, a Ruler, and Father of men, it would follow that the conviction of the existence of one God was the result not of an intuition but of a gradual education. The question cannot be satisfactorily settled on the ground of authority; for even if it be granted that the third chapter of the Book of Genesis sets forth unmistakably a religion in which the doctrine of the Unity and supremacy of the Godhead was united with that of a coequal and coeternal Trinity, we cannot by reference to such a record account for the growth or decay of monotheistic belief in nations cut off from all intercourse with the Semitic race. If it be maintained that the Hellenic Zeus is a corruption of the Supreme God originally revealed (Gladstone, *Homer and the Homeric Age* ii. 43 &c.), we are met by the difficulty that that which is so perverted cannot become clearer and more definite in the very process of corrupt development. On such a supposition not only must the positive truths imparted at first undergo distortion, but the

MONOTHEISM

ideas involved in them must become weaker and weaker; and thus the personality and power of Zeus would be more distinct and real in the earliest times than in the later, which appears not to have been the case. But if we take the earlier Vedic writings as exhibiting the most primitive workings of the human mind with which we are acquainted, it would seem that the consciousness of their own existence led men to attribute life to every object. This life was not necessarily personal, for they had scarcely reached the distinction between consciousness and personality; it was simply confined to consciousness; and every object became a living reality, and every word a speaking picture. Hence arose the mythical speech which described the daily and annual course of the sun [MYTHOLOGY], the succession of summer and winter, and the phenomena of clouds, lightning, earthquake and storms. In all this there was, it seems, no personification, and still less was there any allegory or metaphor; but while such language expressed a sentiment and a belief, it was not strictly a religion. This first condition of thought, which regarded every object in creation as endowed with life, could have *in itself* only two possible developments. It must issue either in an anthropomorphous polytheism, or a degrading fetish worship; in other words, into a multiplication of deities with human forms and passions, or into an abject terror of inanimate things. The former result is exhibited in the mythological system of the Greeks and Latins; but it cannot perhaps be said with truth that this mythology determined the convictions of any who deserved the name of thinkers. All prayed to Zeus; but if the Homeric poems speak of a Zeus who has many earthly loves and is at once arbitrary and sensual, it is equally certain that Achilles does not pray to a lying god who owns no law for himself and cannot be a law for man. If the Hesiodic poets ascribe to the gods horrible banquets, to which Pindar and Plato refused to give credence, the same poets bid all men to follow after justice, because the gods spend their time not in feasting, but in watching the ways and works of men. In short, an examination of the Hesiodic writings seems to establish the position that the grossness and elaborateness of a mythological system is not necessarily a measure or a test of the real religious convictions of a people, or at all events of the thinking portion of a people. Thus, while familiarly handling these mythical tales, Sophocles (*Od. Tyr.* 863) could speak unequivocally of a purity in word and deed which has its birth not on earth but in heaven, and of which the imperishable law is realised in a god as holy and everlasting. The case of the Jewish people is closely parallel; for while the prophets exhibit a sure and steadfast trust in one God who is the Father and Judge of all men, yet their constant remonstrances are sufficient evidence that the great body of the people could scarcely be characterised by any other name than that of

MONOTHELITES

polytheists down at least to the time of the Babylonish captivity. But a further light is thrown on the subject, if we examine those earlier Vedic writings which form 'the oldest book in existence, irrespectively of their age, for, in Prof. Max Müller's words, 'If this collection had been written but fifty years ago, in some distant part of the world untouched by the general stream of human civilisation, we should still call it more ancient than the Homeric poems, because it represents an earlier phase of human thought and feeling.' These writings exhibit with singular clearness and force the growth or the influence of a monotheistic belief. For many striking illustrations we must refer the reader to Professor Max Müller's *History of Sanskrit Literature*, ch. iv. But we may quote his remark that, long before the Hindus 'began to care for the laws of nature, the return of the seasons, the course of the stars, or any other scientific or practical subject, their thoughts were fixed on the one great and ever recurring question, What am I? What does all this world around me mean? Is there a cause, is there a Creator—a God? or is it all illusion, chance, and fate?' Yet, even while the poet admits that 'he knows not what this is that he is like, and that he walks turned inward, chained in his mind,' he adds, 'when the first born of time comes near me, then I obtain the portion of this speech.' In the same hymn in which these words occur there is one verse which explicitly declares the existence of but One Divine Being, invoked under different names. 'They call (him) Indra, Mitra, Varuna, Agni; then he is the well-winged heavenly Garutmat; that which is One, the wise call it many ways; they call it Agni, Yama, Mātariśvan.' In another hymn, the poet, asking repeatedly, 'Who is the god to whom we shall offer our sacrifice?' answers, 'He who through His power is the only King of the breathing and awakening world, He who measured out the light in the air, He who is God above all gods, the Creator of the earth, the righteous, who created the heaven, and the bright and mighty waters.' The hymns in which these passages occur cannot be assigned to any period later than the ninth century before the Christian era; many being probably very much older: it becomes unnecessary therefore to speak of the expressions of a like belief which have been found in the Orphic fragments, in words attributed to Pythagoras, and in verses said to have been sung in the Eleusinian or other mysteries.

Monothelites (Gr. μονοθελῖται, from *monos*, and *theleō*, I will). A sect of heretics, who, while they avoided the error of the Eutychians, and allowed the two natures of Christ to co-exist distinctly in the unity of the person, conceived the influence of the divine will so to predominate over the human substance as to leave to the latter no action or efficiency of its own.

The origin of this doctrine is ascribed to the emperor Heraclius, who, in the year 630. at

tempted to reconcile the Eutychians or Monophysites to the Catholic church by a middle course of this nature, and published an edict, under the advice of some theologians of the day, in assertion of it. This opinion was condemned by some provincial councils and one general council; and, on the other hand, was maintained by the edict of several succeeding emperors. Nor was the question finally settled, though silence was frequently commanded upon it, until it was forgotten in the louder disputes of the Iconoclasts and their opponents.

Monotremes (Gr. *μόνος*, and *τρήμα*, a hole). A tribe of ovo-viviparous Mammalia, of which only two genera are known to exist; viz. the *Platypus* or *Ornithorhynchus*, and the *Ichidna*, both peculiar to Australia. The term is indicative of the common cloacal outlet for the excremental and generative products.

Monotriglyph. In Architecture, such an intercolumniation in the Doric order as brings only one triglyph over each column.

Monotropaceæ (Monotropa, one of the genera). A small order of curious but unimportant parasitical plants, belonging to the Eriac alliance of hypogynous Exogens. They have half-monopetalous flowers, free stamens all perfect, loose-skinned or winged seeds, and an embryo at the pex of the albumen. They are chiefly found in fir woods in cool latitudes in Europe, Asia, and North America.

Monradite. A hydrated silicate of magnesia and protoxide of iron from Bergen, in Norway; named after M. Monrad.

Monrolite. A variety of Kyanite from Monroe, Orange county, New York.

Monseigneur. A title of courtesy in France, which was prefixed to the titles of dukes and peers, archbishops, bishops, and some other exalted personages, and used in addressing them. *Monseigneur* simply, before the Revolution, was the title given to the dauphin. *Monsieur* is now the common title of courtesy and respect in France; and before the revolution in 1830, *Monsieur* simply was the title of the eldest brother of the king.

Monsoons (from a Malayan word signifying seasons). In Physical Geography, the name given to a certain modification or disturbance of the regular course of the trade winds which take place in the Arabian and Indian seas. Between the parallels of 10° and 30° south latitude the eastern trade wind blows regularly; but from the former parallel northwards the course is reversed for half the year, and from April to October the wind blows constantly from the south-west. During the other six months of the year the regular north-east trade wind prevails. The south-west monsoon is supposed to be occasioned by the great rarefaction of the atmosphere over the extensive regions of Eastern Asia during the summer months. [TRADE WINDS.]

Monster (Lat. monstrum). Anything out of the common order of nature is occasionally designated by this term; but it is physiologically employed under a more limited accepta-

tion, and applied to animals in which one or more parts of the body present some congenital malformation. This is sometimes apparent externally, and then must amount to something exceeding any ordinary deformity; or it may be confined to internal organs. Buffon, Blumenbach, and Meckle have treated on monstrosity, classifying its modifications under three heads: the first including cases in which parts of the body are increased in number; the second those where certain organs are deficient; and the third including cases in which size, situation, and structure are concerned. Other writers, such as Geoffroy St. Hilaire (*Histoire des Anomalies*), have adopted more comprehensive arrangements; arising, however, out of the general subdivision of monsters into simple and compound; the former including all cases in which the elements of a single individual only are concerned; the latter those in which the constituent parts of two or more individuals are united. Simple monsters have again been distributed into three classes—the first including such varieties of malformation as chiefly affect one organ or system of organs, without materially interfering with any vital function: these anomalies are extremely numerous, and have been further subdivided into cases where size, form, or structure is affected, and those in which the malformation affects the arrangement, connection, or number of parts. The second class in this arrangement includes cases of extensive malformation, attended by great deformity and by disturbance of vital functions. The third class is limited to malformations of the organs of generation, including among others the various cases miscalled hermaphrodites. The history of individual cases of monstrosity would be here misplaced; several of the most remarkable are detailed in various volumes of the *Philosophical Transactions*; in the *Transactions of the Médico-Chirurgical Society*; and in the *Penny Cyclopædia*, art. 'Monster.'

Monsters or Chimerical Figures. In Heraldry, a species of bearings, of which some are very common in English coats of arms, and others common in foreign, although not often used in our own. The sagittary or centaur, man-tiger, sphinx, harpy, triton, and mermaid, are monsters compounded of the human and bestial shape. Of monstrous beasts, the most common in armorial bearings are the dragon, the griffin (a compound of the eagle and the lion), the wyvern (a two-legged dragon): besides these, there are the unicorn, the heraldic antelope, tiger, and ibex (which are chimerical figures, but representing the natural beast), the musimon (an animal between the goat and the sheep), and the salamander. Monstrous birds are the phoenix, cannet, martlet, allerion, cockatrice, &c.

Mont de Piété (Fr.; Ital. Monte di Pietà). The name given on some parts of the Continent to certain benevolent institutions, established for the purpose of lending money to the poor at a moderate rate of interest. They

originated under the papal government in the fifteenth century, and were intended to counteract the exorbitant usurious practices of the Jews, who formed at that period the great money-lenders of Europe. These institutions were afterwards introduced into many of the Continental states; and similar establishments existed, and in some cases still exist, at Paris, Madrid, Brussels, Ghent, Antwerp, &c. *Monti frumentarii* are public granaries, from which corn is sold to the necessitous Italians, on a principle somewhat analogous to that on which sums are lent by the Mont de Piété.

Montanists. Heretics of the second century, who derive their name from their founder Montanus, a Phrygian (from which circumstance they are also sometimes called Phrygians and Cataphrygians). Montanus asserted that he had received from the Holy Ghost special knowledge on points not made known to the Apostles, and aided by two enthusiastic women, named Priscilla and Maximilla, soon gathered round him a large body of followers. The most celebrated of his adherents was Tertullian. Montanus refused to communicate for ever with persons guilty of notorious crime, and held it unlawful to fly in times of persecution. He also condemned second marriages, and enjoined the observance of three Lents. The sect was subsequently divided into two branches, one following Proclus, the other being composed of the adherents of Æschines.

Montant (Fr.). In Architecture, any upright piece in a system of framing.

Monte Bolca Deposits. The older tertiary rocks of the neighbourhood of Monte Bolca, in North Italy, are so remarkable for the enormous multitude and variety of the fossil remains of fishes which they contain, as to be often specially referred to. They are chiefly muddy limestones, and it is scarcely possible to break open a slab without finding indications of these fossils. Near Mount Lebanon is a similar and almost equally rich locality of about the same geological age.

Montem. The name given to an ancient custom till lately prevalent among the scholars of Eton, which consisted in their proceeding every third year on Whit Tuesday to a tumulus (Lat. *ad montem*, whence the name), near the Bath road, and exacting money for *salt*, as it was called, from all persons present or passers by. The sum so collected was given to the *captain*, or senior scholar of the school, to assist in defraying the expenses of his residence at the university. (Huggett's *MS. Collections* for a history of Windsor and Eton Colleges, in the British Museum; and Brand's *Popular Antiquities*.)

Month (Ger. *monat*, Lat. *mensis*, Gr. *μήν*, from the same root with *μήν*, *moon*, Lat. *mensura*, Sanac. *mā*, *to measure*). The twelfth part of our calendar year. It is so called from its being the period of the moon's revolution round the earth. [CALENDAR.]

Monticellite. A variety of Chrysolite, found in small embedded crystals at Vesuvius.

Named after Monticelli, the Neapolitan mineralogist.

Montmorillonite. A rose-coloured, hydrated silicate of alumina, &c., found at Montmorillon, department of La Vienne.

Monument (Lat. *monumentum*). A memorial for perpetuating the remembrance of an event; also a cenotaph in memory of the dead. The productions of architecture and sculpture intended to transmit to posterity the memory of individuals and events are most generally called *monuments*. Among those in honour of individuals are tombs and sepulchral edifices or columns. The most ancient are the obelisks and pyramids of Egypt. Greece abounded with monuments of this nature. Among such buildings were the Choric monuments, in honour of those who had received the prize as *choragi* in the theatrical and musical games; and of these the most splendid is the choragic monument of Lysicrates, vulgarly called the Lantern of Demosthenes. Among Roman monuments of this class the triumphal arches are in the first rank. The column called the Monument of London, and the Duke of York's column, illustrate respectively the definition above given.

Mood (Lat. *modus*). In Grammar, the designation, by the form of the verb, of the manner of our conception of an event or fact, whether as certain, contingent, possible, desirable, or the like. [GRAMMAR.]

Mood of a Categorical Syllogism. In Logic, the designation of the three propositions of a syllogism in the order in which they stand, according to their quantity and quality.

Moon (Gr. *μήνη*, Ger. *mond* [MONTE]). The satellite of the earth. The moon, after the sun, is not only the most conspicuous, but, in an astronomical point of view, the most interesting of the celestial bodies. The variety of her phases, her eclipses, and the rapidity with which she changes her place among the fixed stars, drew the attention of the earliest observers of the heavens; and in modern times the important application of the theory of her motions to navigation and the determination of terrestrial longitudes, has given the *Lunar Theory* the first rank among the objects of astronomical science.

Phases of the Moon.—The different phases of the moon were probably the first celestial phenomena that received a correct explanation. By observing them attentively during the course of a single revolution, it would be inferred that they are occasioned by the reflection of the sun's light from the spherical surface of the moon; and accordingly the fact had been recognised by the earliest astronomers. Let T be the place of the earth, and A B C D E F G H successive portions of the moon in her orbit, the sun being supposed to be situated in the straight line T A, and at so great a distance that lines drawn from it to every part of the moon's orbit may be regarded as parallel. When the moon is at A, she is in *conjunction*

MOON

with the sun, and passes the meridian at the same time; and her illuminated hemisphere being then turned directly away from the earth, no portion of her disc is visible. A few days after the conjunction the moon begins to

appear on the eastern side of the sun at B, having the form of a crescent, the horns of which are turned eastward, or away from the sun. When she arrives at C, or 90° from her conjunction, the earth is in the plane of the great circle of her orb,

which forms the boundary between her dark and illuminated hemispheres, and consequently half the disc is visible. The moon is then in her *first quarter*. At D more of the illuminated hemisphere is turned towards the earth, and she appears gibbous. At E she is in opposition to the sun; the illuminated side is turned directly to the earth, and the disc appears round or *full*. After passing E the disc begins to wane, and from E to G appears gibbous. When at G, or 270° from the conjunction, she is in the *third quarter*. From this point to the conjunction the moon again appears as a crescent, becoming narrower as she approaches to A; but the horns of the crescent are now turned westward, still away from the sun. The straight line which joins A and E is called the line of the *syzygies*; that which joins C G is the line of the *quadratures*; and the points B D F H, situated at equal distances from those lines, are called the *octants*. The magnitude of the illuminated portion of the disc is thus seen to depend on the position of the moon relatively to the sun and the earth, and is easily determined by a geometrical construction. The mean period of time in which a revolution of the phases is completed, or in which she passes from one conjunction to the following, is 29 d. 12 h. 44 m. 2.8 s.

Distance and Magnitude of the Moon.—The moon's distance from the earth is found from her horizontal parallax, which may be determined either by simultaneous observations at stations very distant from each other, or by means of the occultations of fixed stars by the moon. From such observations it is found that the amount of the parallax varies considerably at different times. Its mean value gives the average distance of the moon from the earth, equal to 59.9 of the earth's equatorial semidiameters, or about 237,000 miles, which is upwards of 400 times less than the distance of the sun. Combining this result with the apparent magnitude ($31' 26''$) of the moon's diameter, when at her mean distance, it results that the diameter of the moon is to that of the earth in the proportion nearly of 3 to 11; whence the volume of the moon is only about 1.49th of the volume of the earth.

A recent discovery has shown us that the telescopic diameter of the moon is about $2''$

larger than the real one. This may be due to irradiation entirely, or to irradiation and an atmosphere.

Inclination and Nodes of the Lunar Orbit.—The moon's orbit is inclined to the ecliptic under an angle of $5^\circ 8' 47.9''$; but the line in which it intersects the ecliptic, or the *line of the nodes*, does not maintain a fixed position on the plane of the ecliptic. It is observed that the moon passes from one of the nodes to the opposite one in less time than is required to pass through 180° of longitude; hence the line of the nodes has a retrograde motion on the ecliptic; and its motion is so considerable that it completes a revolution, or returns to its former position, in a period of 6798.28 days, or about 18.6 years. This period is remarkable, as being that after which the eclipses of the sun and moon again return nearly in the same order. The cause of the regression of the line of the nodes is the attractive power of the sun, which is always tending to draw the moon into the plane of the ecliptic, and which would at length cause her orbit to coincide with that plane, were the tendency not counteracted by the angular motion of the moon round the earth. By reason of the angular motion the mean inclination remains the same, and the resulting effect is the retrograde motion of the nodes. But as the sun's distance from the earth is a variable quantity, the effect of the solar action in displacing the moon's orbit is also variable. Hence, and also on various other accounts, the motion of the nodes, and the inclination of the lunar orbit to the ecliptic, are subject to certain periodical changes, all which must be accurately appreciated and computed in the formation of the lunar tables. [PERTURBATIONS.]

Eccentricity of the Lunar Orbit.—The general orbit of the moon is an ellipse, having the earth at one of its foci; but on account of the disturbing force of the sun, and the difference of the intensities of this force when the moon is differently situated relatively to the earth and sun, the ellipse is constantly changing its form and position on the plane of the orbit; and hence the numerical values assigned to all its elements are to be considered only as average or mean values. The distance of the moon from the earth when in *apogee*, or at her greatest distance, is 63.844 semidiameters of the earth; and when in *perigee*, or at her least distance, 55.916 semidiameters; whence the eccentricity, or distance of the focus from the centre, is about 0.066, half the major axis being taken as unity. According to the best tables, it is 0.0548442. On comparing the positions of the major axis, which is called the line of the *apsides*, at different times, in respect of the fixed stars, it is found to have a rapid motion eastward, completing a whole circuit in 3232.57 mean solar days, or nearly nine years. But this mean motion is subject to inequalities of considerable magnitude. The different situations of the line of the apsides with respect to the line of the syzygies gives

rise to the inequality of the lunar motion, called the *vection*. [Evection.]

Different Species of Lunar Months.—As the principal points of the lunar orbit—the syzygies, the nodes, the apsides—are in a state of rotation with different velocities, and in different directions, it follows that the period of time in which the moon completes a revolution with respect to any of these points, or to the fixed stars, will be different in each case. These periods, which are called *lunar months*, may be explained as follows: Let E be the

centre of the earth, $a s b t$ the orbit of the moon, $a b$ the transverse axis or line of the apsides, $s t$ the line of the syzygies, $n m$ the line of the nodes, and $A S B N$ the great circle of the sphere in the plane of the ecliptic. Also, let

P be a fixed point on this circle; and suppose the moon to be at p , or seen in the direction $E P$. The time which elapses while the moon passes from p , and returns to the same point of the ecliptic, is called the *tropical* revolution, and differs only about seven seconds from the time in which the moon returns to the same fixed star, or performs a *sidereal* revolution. Suppose now the moon to be at s , in the line of the syzygies; when the moon advancing from s , in the direction $m b n$, has again come round to the same point of the ecliptic, she will not now be in conjunction; for, in the interval, the sun has advanced from S to S' (nearly a twelfth of the circumference), and consequently the moon must go on to s' , till she overtakes the sun, before she returns to her conjunction. The interval from conjunction to conjunction is the *synodic period*, and exceeds the tropical period by two days and about five hours. Next, suppose the moon to be at her perigee a , or seen in the direction $E A$; while the moon, after leaving a , is describing her orbit, the line of the apsides $E A$ revolves through the angle $A E A'$, and consequently the moon, after coming into the line $E A$, must continue to advance till she comes to a' before she arrives again at her perigee. The interval from perigee to perigee is called the *anomalous period*; and it is also longer than the tropical period, though much shorter than the synodic, inasmuch as the line of the apsides requires about nine years to complete its revolution, while that of the syzygies is completed in one year. Lastly, suppose the moon at n in the line of the nodes. While the moon is advancing round her orbit, the line of the nodes, $E N$, moves backward into the direction $E N'$; consequently the moon will have come up to her node at n' before she has completed a revolution on the ecliptic. The interval from node to node is called the *nodical period*, and is shorter than any of the other periods. The following table exhibits, in mean solar days, the mean lengths of the different lunar periods or months:—

	Days
Synodic revolution	29·53069
Sidereal	27·32166
Tropical	27·32168
Anomalous	27·55460
Nodical	27·21223

Acceleration of the Moon's mean Motion.—

On comparing observations of the moon made at distant intervals of time, it has been discovered that her mean motion has been undergoing a constant acceleration since the earliest times. This acceleration is, however, extremely small, amounting only to $10''$ in a century, and therefore is insensible for any moderate interval of time, though it becomes discernible after a few centuries. Being measured by centuries, it is called the *secular acceleration* of the mean motion. Its physical cause was found by Laplace to be a diminution of the eccentricity of the earth's orbit. For descriptions of *eclipses of the moon*, *eclipses of the sun by the moon*, *rotation and libration of the moon*, see *ECLIPSES* and *LIBRATION*.

Appearance and Physical Constitution of the Moon.—

On looking at the moon with the naked eye, her disc appears diversified by dark and bright patches, which are due to the unequal reflection of light by different portions of the lunar surface, and not to mountains and valleys as is commonly supposed. A very moderate telescopic power, however, suffices to show that nearly the whole surface of the moon is covered with elevations and depressions, which are especially evident at the line of separation (called the *terminator*) between the illuminated and dark hemispheres. This line, which, if the surface were even, would be sharply defined, is at all times extremely ragged, and indented with deep recesses and prominent points. The mountains near it cast behind them long black shadows (as do mountains on the earth when the sun is in the horizon), from the micrometrical measurement of which the height of the mountains may be calculated. According to Sir J. Herschel, some of the highest of them exceed $1\frac{1}{2}$ English mile in perpendicular altitude. Tycho, the bright spot in the south-east quarter from which the rays seem to run, is apparently a volcanic crater, 50 miles in diameter and 16,000 feet deep, surrounded by broad terraces within, and with a central mountain about 5,000 feet high. Schroeter has estimated the average height of the lunar mountains to be upwards of five English miles; but it is easy to see that the measurement is not susceptible of much accuracy.

'The generality of the lunar mountains,' says Sir J. Herschel, 'present a striking uniformity and singularity of aspect. They are wonderfully numerous, occupying by far the larger portion of the surface, and almost universally of an exactly circular or cup-shaped form, foreshortened, however, into ellipses towards the limb; but the larger have for the most part flat bottoms within, from which rises centrally a small, steep, conical hill. They

MOONSTONE

offer, in short, in its highest perfection, the true volcanic character, as it may be seen in the crater of Vesuvius; and, in some of the principal ones, decisive marks of volcanic stratification, arising from successive deposits of ejected matter, may be clearly traced with powerful telescopes. What is, moreover, extremely singular in the geology of the moon is, that although nothing having the character of seas can be traced (for the dusky spots which are commonly called seas, when closely examined, present appearances incompatible with the supposition of deep water), yet there are large regions perfectly level, and apparently of a decided alluvial character.' ('Astronomy,' *Cabinet Cyclopaedia*, p. 229.)

The moon has no atmosphere, or at least none of sufficient density to refract the rays of light in their passage through it. There is consequently no water on her surface; and no animal similarly constituted to those which inhabit the earth could subsist there. Her surface presents no appearance of vegetation, or of variation which can be ascribed to a change of seasons. Everything appears solid, desolate, and unfit for the support of animal or vegetable life. Whether the materials of which the lunar substance is composed are of the same nature as those which compose the earth, there are no means of knowing. From the effect of the moon's gravitation in producing the nutation of the earth's axis, the mass of the moon is determined to be very nearly 1-80th of the mass of the earth; whence, as her volume is only 1-49th of the earth's volume, it results that her density, as compared with the mean density of the earth, is .615, or a little more than one-half.

Moonstone. A transparent or translucent variety of Adularia, which, by reflected light, presents a pearly or silvery play of colour, not unlike that of the moon. It is held in considerable estimation as an ornamental stone, especially on the Continent, and is sometimes cut into ring and brooch stones. The finest specimens are brought from Ceylon.

Moor. An uncultivated surface without trees, with few grasses or other herbage fit for pasture, and generally containing scattered plants of heath, with a dark peaty soil. Moor lands are generally the least fitted for culture of any kind of surface, not rocky or mountainous. Moors are covered with a very thin layer of soft, black, sterile soil; and the subsoil is generally gravel, or retentive ferruginous clay. By the destruction of the heath, or other bad herbage, by deep tillage and the use of lime, and manuring with bone-dust, guano, &c., as may be practicable, and by sowing down with grass seeds, they may be improved. In many cases, also, trees will grow on drained moors; in which case the soil ultimately becomes ameliorated by the fall and decay of the leaves.

Moor (Dutch *marren*, to tie; Fr. *amarrer*). In Navigation, this word signifies generally to fix a vessel by two anchors in nearly opposite

MORANA

directions, so that she *rides* by either in certain winds, or partly by both in other winds; also to secure a vessel to weights or chains sunk in harbours for the purpose. These weights are called *mooring blocks* and the whole apparatus *moorings*.

Moorballs. The curious sponge-like balls found at the bottom of fresh-water lakes, and consisting of plants of *Conferva agagropila* in their natural state. The whole plant, observes Mr. Berkeley, consists of a mass of branched articulated green threads, somewhat resembling the hair-balls found in the stomachs of ruminants.

Moorish Architecture. [ARCHITECTURE.]

Moplahs. The Mohammedan inhabitants of Malabar, descended from Moors and Arabians who have settled on that coast and married Malabar women. They are said to form a fourth of the population. They are commercial and industrious on the coast, but have occasionally shown themselves a furious race in the interior. (Forbes, *Oriental Memoirs*, p. 258.)

Mora (its native Guiana name). A genus of *Leguminosae* comprising the Mora of Guiana, a gigantic timber tree, 100 to 150 feet high, of which extensive forests exist both in Guiana and Trinidad. The wood is very tough and close-grained, and under the name of Mora timber is largely imported for shipbuilding. One of its most valuable properties is its non-liability to splinter. The species is called *M. excelsa*.

Moraceae (Morus, one of the genera). A natural order of diclinous Exogens of the Urtical alliance, distinguished by the technical peculiarities of having solitary suspended ovules, and a hooked albuminous embryo with a superior radicle. They are trees or shrubs with variously formed leaves, commonly rough, accompanied by large stipules, and small unisexual flowers collected into heads, spikes, or catkins. They occur both in temperate and tropical climates, and abound in milky juice, often yielding caoutchouc. The order embraces the Fig family (*Ficus* with its offshoots), and the Mulberries (*Morus*), with a few other genera.

Moraine. A Swiss term, introduced into the technical language of Geology, meaning the débris or broken fragments of rocks brought down into the valleys below by glaciers. Such moraines are common in the Alps and in other lofty mountain chains. They are found also occasionally where there are now no great glaciers. They assist greatly in determining the history of some of the more remarkable deposits of gravel in Europe. [GLACIER.]

Morals. [ETHICS.]

Morana. The old Bohemian goddess of winter and of death: the Maryana of Scandinavia. A grand yearly festival was celebrated in honour of this goddess in the month of March. Her image was conveyed solemnly to the nearest brook or rivulet, and thrown into it amid the rejoicings of the people. This festival was called *Das Joden-Austreiben*, *das*

MORASS

Sommer gewinnen; and, as the words imply, was intended to be symbolical of the end of winter and the return of spring. (Grimm's *Deutsche Mythologie*, p. 446.)

Morass. Moor lands saturated with water to such an extent as not to bear the tread of cattle. A morass is to a moor what a marsh is to a meadow. It is evident that the drainage of morasses and moors, by lessening the evaporation of water from their surfaces, must tend to improve the local climate.

Moravian Brethren. [HAERENHUT.]

Morbidesza (Ital.). In Painting, a softness and delicacy of style. Its opposite is a style in which the lines are harsh and angular.

Mordant (Fr.; Lat. *mordeo*, *I bite*). A substance used to fix colouring matters upon different stuffs. [DYEING.] Alumina and oxide of iron are among the most important mordants.

Mordella (Lat. *mordeo*, *I bite*). A Linnean genus of Coleopterous insects, the type of a family (*Mordellidae*) of Latreille's *Heteromera*, distinguished by the general form of the body, which is elevated and arched; with the head low; the thorax trapezoidal or semicircular; the elytra very short, or narrow and pointed at the tips, as well as the abdomen. They are distinguished from their nearest congeners, as the *Pyrochroidae*, by their extreme agility, the firm texture of their integuments, and their tenacious and painful bite. The subgenera of the *Mordellidae* are *Rhipiphorus*, *Myodites*, *Pelecotoma*, *Anaspis*, and *Mordella* proper: to the last subgenus are now restricted the species of the present family, which have the antennae of equal thickness throughout, and slightly serrated in the males; the eyes not emarginate, and the abdomen terminated by a long point.

Mordenite. A zeolitic mineral found in the form of concretions in a trap rock near East Morden, in the bay of Fundy.

Mordente (Ital.). In Music, a grace in use by the Italian school, which is effected by turning upon a note without using the note below.

Morel (Ger. *morchel*). The *Morchella esculenta*, one of the few fungi found in this country which may be used as food with safety. It occasionally occurs in woods and orchards, whence it finds its way to the markets; but it is of comparatively rare occurrence. It has a hollow stalk an inch or two high, and a yellowish or greyish ribbed head two or three inches deep.

Moresque (Fr.). In Painting or Sculpture, a species of Arabesque or Saracenic ornament, in which foliage, fruits, flowers, &c. conventionally treated, are combined, by springing out of each other, without the introduction of the human figure, or that of any animals. It has received its name from having been much used by the Moors, who, however, were not the inventors of it. It was developed by Byzantine Greeks, who were employed by the early Arab conquerors in the decoration of their mosques,

MORMON

in which no imitation of nature could be tolerated. Much of this ornament is still preserved in Egypt, in Sicily, and in Spain.

Morganatic Marriage or **Left-handed Marriage** (said to be derived from the Gothic word *morgjan*, to shorten). A marriage between a man of superior and a woman of inferior rank, in which it is stipulated that the latter and her children shall not enjoy the rank or inherit the possessions of her husband. Such marriages are not uncommon in the families of sovereign princes, and of the higher nobility, in Germany; but they are restricted to personages of these exalted classes.

Morgue (Fr.). The name given to a place in many French towns where the bodies of persons found dead are exposed in order to be recognised and owned by their friends. The clothes in which they were found are placed near the bodies, for their better identification. The Parisian morgue is built on the left bank of the Seine, in one of the most populous neighbourhoods of the city.

Moric Acid. *Morin*. A variety of tannic acid existing in the wood of *Morus tinctoria*, or *fusca*.

Morinda (Gr. *μύρον*, the mulberry). This genus of *Cinchonaceae* yields the plant from which the Ach-root is obtained. The plant is named *M. tinctoria*, and this, together with *M. citrifolia*, *bracteata*, and *umbellata*, is used for dyeing purposes in India and Ceylon.

Morindin. A crystallisable substance obtained from the root of *Morinda citrifolia*.

Moringaceae (Moringa, one of the genera). A natural order of hypogynous Exogens, belonging to the Violal alliance. It includes but few species, small trees with bi-tripinnate leaves, and white panicle flowers. These are found in India and Arabia. *Moringa pterygosperma* is a stimulant and rubefacient, and its seeds form the Ben-nuts of old writers. The order is known by its many-leaved calyx, its perigynous petals and stamens, its one-celled anthers, its stipulate siliquose fruit, and its exalbuminous seeds.

Moringic Acid. An oily acid obtained from oil of ben, which is expressed from the fruit of *Moringa pterygosperma*.

Morion. A lapidaries' name for black Rock Crystal. Also, a helmet worn by men-at-arms.

Moritanic Acid. A modification of tannic acid, forming part of the colouring matter of fustic (*Morus tinctoria*).

Mormon (Gr. *μορμόν*, or *μορμώ*, a mask). The generic name for the short-winged web-footed birds, usually called Puffins, the singular beak of which gives the head the appearance of a grotesque mask. The depth of the base of the bill equals that of the entire head, and frequently the length of the bill itself: the mandibles are compressed, arched, obliquely channelled, and notched towards the tip. The eggs and young birds are sought after and taken in great numbers in the Orkneys and Faroe Isles.

MORMONISM

The name commonly given to a religious system of which the head quarters are now in the United States of America, although many congregations of its sectaries exist both in Britain and on the continent of Europe. The 'Mormons' are also termed *Letter-day Saints*. The founder of the sect was one Joseph Smith, an American of Vermont, settled in the state of New York. His religious romance, *The Book of Mormon, an Account written by the Hand of Mormon, upon Plates taken from the Plates of Mormon*, was first printed at Palmyra, New York, in 1830. It was followed by his *Book of Doctrines and Covenants of the Church of Jesus of Latter-day Saints*, in 1832. *The Latter-day Saint's Millennial Star*, a periodical still continuing, and the *Journal of Discourses*, by Brigham Young (the present chief of the sect), and others appearing in semi-monthly numbers, are regarded as the authoritative exposition of the creed of this body. The Mormons, under the leadership of Joseph Smith, multiplied and prospered in the United States, though not without persecutions, until 1844, when their establishment at Nauvoo, in Illinois, was sacked and destroyed by a popular movement, and Joseph Smith himself murdered by a mob. In 1846 the Mormon exodus from Illinois began, under Brigham Young, who in 1846 had assumed the 'presidency of the twelve apostles,' and became the leader of the church. In 1848 they established themselves in 'Great Salt Lake City,' in Utah territory, a region among the Rocky Mountains, in the central portion of the North American continent. Here they have since maintained themselves, not without frequent collisions with the authorities of the United States, sent in virtue of the constitution to maintain the Federal Government among them. The 'saints' in Utah are commonly estimated at from 40,000 to 50,000 souls: there are said to be 40,000 members in the 'European mission,' and the annual emigration to Utah, carried on mainly by a common fund (before the late war in the States), was 3,000 or 4,000; but these numbers must be received with much distrust; the Mormon authorities themselves rate them far higher. Mormonism derives its recruits chiefly from England, Wales, and the northern parts of Europe.

The original impulse towards Mormonism lay in that craving after the continuance of a visible governing, miracle-working authority in the church, which Roman Catholicism recognises and satisfies, but which in Protestant communities finds vent in the constant succession and temporary popularity of sects such as the Irvingites, Plymouth Brethren, and so forth. But it may well be thought that nothing except an extremely low state of education, and almost total absence of religious training, could have brought tendencies and cravings such as these into connection with the coarse and even ludicrous pretensions of such a personage as Joseph Smith. His *Book of Mormon*

is described by the Rev. H. Caswall, author of one of the earliest accounts of the sect, to be nothing but a plagiarism from an unpublished romance, in biblical style, written by one Solomon Spaulding, a minister of religion. However this may be, the imaginary 'plates' on which the revelation was inscribed have never been revealed to any eyes but those of the prophet himself. It professes to record the history of the family of Lehi, and his son Nephi, who left Jerusalem a.c. 600, and introduced the worship of the true God into America; the 'Nephites' received Christianity through the direct interposition of our Saviour Himself; and were finally destroyed by infidels, A.D. 421, when Moroni, the last survivor, finished and sealed up the 'records,' which in the fulness of time came into the hands of Joseph Smith. But the system of belief now preached by them is not to be learnt from these fanciful records, but from subsequent commentaries. They profess belief in the Trinity and Atonement: in the ordinances of faith, baptism by immersion, laying on of hands, and the holy supper: in an apostolic succession of the ministry: in the continuance of 'gifts' to the church; namely, prophecy, revelations, visions, healings, tongues, &c.: in the second coming of the Messiah: in the literal gathering of Israel, the restoration of the ten tribes, and in the personal reign of Christ for a thousand years. [MILLENNIUM.] The principle and practice of polygamy, now commonly regarded as the most characteristic part of their institutions, did not exist among them from the beginning, but were authorised by 'A Revelation on the Patriarchal Order of Matrimony, and Plurality of Wives,' made to Joseph Smith in 1843. The hierarchy of the Mormons consists of several orders: 1. The 'first presidency' of three members, over whom, however, the first, now Brigham Young, has supremacy: 2. The 'patriarch,' a kind of office of dignity rather than government: 3. The second presidency of twelve: 4. The seventy: 5. The high priests, including the 'bishops' or superintendents, and the 'high council' of twelve, a sort of spiritual court of justice between believers. For accounts of the early Mormon history may be particularly consulted the publications of Lieut. Gunnison and Col. Kane, United States officers: for hostile, but more or less trustworthy, sketches of their faith and practice, those of J. C. Bennett, an apostate from their persuasion; the Rev. H. Caswall, chap. xiii. of *America and the American Church*, 1851; Conybeare 'On Mormonism' (*Edinburgh Review* for 1854); the narratives of Mrs. Mary Etie and other female writers, on the usages of Mormonite polygamy; Montégut, 'Le Mormonisme' (*Revue des Deux Mondes*). But this article has been chiefly compiled from the information contained in one of the last works on the subject, the *City of the Saints*, by the well-known traveller Richard F. Burton, a work written in an unusual spirit of favour towards this great imposture and its professors.

MORMYRUS

Mormyrus (Gr. *μормύρος*, a name given by the Greeks to a shore-frequenting fish of a variegated colour, probably the *Sparus Mormyrus* of Linnaeus). The name was applied by Linnaeus to a genus of abdominal fishes placed in the Malacopterygian order, between the *Lucioid* and *Siluroid* families in the system of Cuvier. The *Mormyri* differ from the pikes in little else save in the small size of their mouth, of which the angles are formed by the maxillary bones; and in a corresponding modification of the alimentary canal, the intestines being longer, and complicated by two caeca. The *Mormyri* are confined to the rivers of Africa, and are reckoned the best-flavoured fishes that are caught in the Nile.

Moresco (Fr. *maroquin*). A species of goatskin leather, originally imported from the Levant and Barbary states. It is extensively used in the binding of books. [LEATHER.]

Moroneben. The Hog-gum tree, *M. cocinea*, is a loft: South American and West Indian tree, belonging to the *Clusiaceae*, and forms a straight trunk one hundred feet high, with smooth horizontal branches, and thick entire glossy leaves. A juice exudes from incisions of the trunk. This juice hardens into a yellowish resin, and has been employed medicinally as a substitute for copaiba. In Brazil and Guiana the natives use it for torches, and to pitch their boats.

Moroxite (Gr. *μόροτος*, the name of an Egyptian stone). An opaque greenish-blue variety of Apatite from Arendal in Norway, and Pargas in Finland.

Moroxylie Acid. An acid discovered by Klapproth in the bark of the *Morus alba*, or white mulberry-tree.

Morpheus (Gr.). In Ancient Mythology, the god of dreams; the son of *Ψυχός* or Somnus, so called as shaping or fashioning the dreams of the sleeper.

Morphia (Lat. *Morpheus*). The narcotic principle of opium. It may be separated from opium in the form of white prismatic crystals almost insoluble in water, but soluble in boiling alcohol; it combines with the acids and forms salts, all of which are sedatives, and of great therapeutic value as medicines. Of these the hydrochlorate of morphia is perhaps the best. The acetate of morphia is also a valuable preparation. One of the most characteristic chemical properties of morphia and its salts is that they decompose iodic acid, and consequently immediately discolour its aqueous solution. The ultimate elements of morphia are carbon, hydrogen, oxygen, and nitrogen, and may be represented by the formula $C_{25}H_{20}O_4N$. [OPIUM.]

Morphnus (Gr. *μόρφνος*, *dusky*, a name applied by Aristotle to the osprey). This term is restricted by Cuvier to a genus of *Accipitres* called eagle-hawks, having wings shorter than the tail, but with long and slender tarsi and comparatively feeble toes. Some species have the tarsi naked and scutellated, as the *Morphnus guianensis*.

MORRICE DANCE

Morphology (Gr. *μορφή*, *form*, and *λόγος*). In Botany, that department or division of the science which treats of the metamorphosis of organs. It appears, from the comparison of one kind of organ with another, that notwithstanding the differences between them, there are so many close analogies, and so much identity of structure, as to render it probable that they are all formed upon one common plan, modified according to the purposes for which they are severally destined. The leaf, which is the most universal of the external organs, is taken as the best representation of this type; and with the more reason, because all the other parts are found to have a tendency to assume the organisation of a leaf, when any disturbing cause interferes with their development. According to morphological writers, the scale of a leaf bud is a rudimentary leaf; the petal is a leaf reduced in size, and thinned or coloured, or both; the stamen is a leaf, whose petiole is represented by the filament, while the two lobes of the anther are the two sides of its lamina; and the pollen is the disintegrated mesophyll, and so on. These conclusions were for a long time ridiculed by many writers; but they gradually gained ground with philosophical botanists, and are now the foundation of comparative anatomy in plants. At the present day the question is indeed no longer speculative, but is decided by the evidence of our eyes; for all those transformations the necessity of which morphologists assumed by mere force of reasoning have now been witnessed by Schleiden and many others, who have traced the development of the organs of plants from their earliest condition, through all their modifications, up to the period of complete development, and have found that they are all deviations from a common type subsequent to the first stage of their growth.

In Zoology, morphology is the history of the modifications of form which the organ undergoes in the same or in different organisms. The science has been advanced during the last twenty years by the labours of the so-called *transcendental anatomists*, and has been most successful when applied to the modifications of the vertebrate skeleton. The principles on which the science is founded are detailed in the articles *ARCHETYPE*; *HOMOLOGUES*; *SKELETON*; and *VERTEBRA* [which see].

Morrice Dance or **Morris Dance** (a corruption of Moresco or Moorish dances). A peculiar kind of dance practised in the middle ages. It is supposed to have been first introduced into England from Spain by Edward III., when John of Gaunt returned from that country; but few traces of it are found earlier than the times of Henry VIII.; and it is more probable that it was borrowed either from the French or the Flemings. In the morris dance bells were fixed to the feet of the performer, and the great art consisted in so moving the feet as to produce something like concord from the various bells.

MORS

(Lat. from the root *mar*, to pound or grind [*LANGVARS*]). In Latin Mythology, the goddess of death.

Mortality, Bills of. Bills of mortality are extracts from parish registers, showing the numbers who have died in some fixed period of time, as a year, a month, or a week; and hence they are called *yearly, monthly, or weekly bills*. In general, they also contain the numbers of baptisms, and sometimes the numbers of marriages. To be correct, these bills should state the condition of all that die at every age, whether boys, married men, widowers, or bachelors; the corresponding distinctions being likewise given for females. Such lists of persons of both sexes dying of every disease in every month and at every age would, when compared with records of seasons and local circumstances, tend greatly to the increase of medical knowledge, and afford the necessary data for determining the duration of life between males and females.

The keeping of parish registers was begun in England in the year 1638, in consequence of an injunction issued by Lord Cromwell, the king's viceregent in ecclesiastical affairs, after the abolition of the papal authority in the kingdom. In Germany they appear to have been introduced at a somewhat earlier period, for Süssmilch has given extracts from the Augsburg bills which go back to the year 1601; and they were established in most countries of Europe about the beginning of the seventeenth century.

The London bills, containing the records of baptisms and deaths, were begun in the year 1692, but were not kept regularly till after the plague which prevailed in 1603; since which time they have been continued weekly, and an annual bill has been also regularly published. Their value, however, was very little understood; nor do they seem to have attracted much notice until 1662, when Graunt published his *Natural and Political Observation on the Bills of Mortality*, a work of great merit, considering the time at which it was written. The ages at which the deaths took place were not inserted in the bills till 1728. Throughout the country the registers were kept, generally speaking, with very little care; but the Act for the registration of births, marriages, and deaths, which came into operation in 1836, has introduced an incomparably better system; and, as the sex, ages, and causes of death are now recorded, the public is in possession of far more authentic information than before existed on some of the most interesting questions of social statistics. (See article 'Mortality,' in the *Encyclopædia Britannica*, 8th edition; Preface to the *Population Returns for 1831*; *Annual Reports of the Registrar-General of Births, Deaths, and Marriages in England*, 1839 et seq.; *Price On Reverendary Payments*.)

Mortality, Law of. By this term is usually understood a mathematical relation subsisting among the numbers of persons

MORTALITY

living at the different ages of life; such that, the number of persons living at any assigned age being given, the number of them who remain alive at every subsequent age, and consequently the mortality which takes place in the interval, will be expressible by that relation. It must be obvious that in speaking of a law of this kind, we can only have regard to the averages of large numbers. In respect of a single individual, or a small number of persons, the uncertainty of the duration of life is proverbial; but the case is entirely changed when multitudes are concerned; and there are few classes of contingent events of which the results can be predicted with so little risk of departure from the truth as the average age to which the lives of a considerable number of persons will be prolonged.

The circumstances which affect the mean duration of human life depend upon a great number of different causes; as climate, the facility of obtaining subsistence, the state of civilisation, the manner of living, progress of medical science, &c., all of which vary in different countries and at different times. The law of mortality, therefore, must vary with these circumstances; and consequently, if expressible by any mathematical function, it must be one affected by numerical coefficients depending on the particular circumstances, and of which the values can only be determined by observation. The simplest expression which has been proposed for representing the course of mortality is that which is derived from the celebrated hypothesis of De Moivre; namely, that if a number of individuals be taken in any given year of age, the number of deaths which take place among them will be the same every year until the whole are extinct. In this hypothesis only one numerical quantity requires to be determined, viz. the average extreme age. De Moivre adopted 86; and his hypothesis may therefore be simply enunciated as follows: Out of 86 infants born, 86 will be alive at the end of the first year, 84 at the end of the second, and so on to the extremity of life, the decrement being one in each year. For a considerable number of years, about the middle ages of life, this hypothesis of equal decrements represents the observed facts with tolerable accuracy; and, as it affords considerable facilities in various calculations, it was formerly much used in the computation of life contingencies. The difference between the given age and 86 is called by De Moivre the *complement of life*; thus the complement of a life of 50 is 36 years.

If we suppose a straight line to be divided into a number of equal parts, representing the ages of human life, and perpendiculars to be drawn through the points of division proportional to the number of survivors at each age out of a given number taken at a previous age; a curve line drawn through the extremities of all those perpendiculars will represent the law of mortality as indicated by the observations, and the equation of the curve will be the relation between the age and the mortality.

MORTALITY

Now it is possible to draw an algebraic curve through any number of points; but, in the present case, this method of proceeding is attended with no advantage; for if the number of points be great, as it necessarily must, the equation is of a high order, and its numerical computation impracticable. Lambert, of Berlin, who appears to have been the first who exhibited the law of mortality by a curve line, constructed a somewhat complicated empirical formula, which represented the mortality observed in London during some part of the last century with considerable accuracy, and which may be adapted to any other set of observations by giving suitable values to its numerical coefficients. But the most ingenious attempt which has been made to deduce a formula from *a priori* considerations is contained in a paper by the late Mr. Benjamin Gompertz, published in the *Philosophical Transactions* for 1825. Mr. Gompertz assumed as a principle that there is a power in human life to resist the effects of disease, or oppose destruction, which loses equal proportions of its intensity in successive equal small intervals of time; and from this he derived an expression which gives the number of survivors (y) of any number of individuals, taken at any given age, at the end of any number of years (x) counted from that age, in terms of three constants, which may be determined from observations. The formula may be given under this form:—

$$\log y = \log l + \text{No. whose log is} \\ (\log p + x \log q),$$

l , p , and q being the constants to be determined. On assuming three ages, and taking the corresponding values of x and y from the Carlisle table, and determining the constants by means of the three equations so formed, the formula is found to agree with the table through all the ages, within limits which may be fairly supposed not to exceed the errors of the observations. A supplement to Mr. Gompertz' paper of 1825 will be found in the *Phil. Trans.* for 1862.

On account of the multitude of causes which influence the rate of mortality among the inhabitants of a country, it is plain that any formula deduced from *a priori* considerations can only be trusted so far as it is found to agree with experience; and therefore, for all practical purposes, recourse is had to a table showing for each year of age the number of deaths which are observed to take place out of a large number of persons who enter upon that age. The ratio of those two numbers is the measure of the probability that an individual entering upon that age will not survive the year, and may be assumed as the law of mortality in respect of that age. The table may be exhibited under different forms: the most usual is a table of decrements, which is constructed by supposing a large number of persons, as 10,000, for example, to start together in the same year of age (the year of birth is usually assumed), and to write down

in the same column the number of those who remain alive at the end of each successive year. From this the number who die in each year, and the chances of surviving a year, or any number of years, are easily found. For some purposes the table of the probabilities of living over a year at each age, or of dying in the course of the year, is more convenient; but either form can be readily reduced to the other.

The first outline of a life table was traced by Graunt in his *Observations on the Bills of Mortality* 1662–1678; but the oldest complete table which we possess is published in the *Philosophical Transactions* for 1693, and was constructed by Halley from the mortuary registers of Breslau, in Silesia. This town was selected, because the number of births having been nearly equal to the number of deaths for some years, it might be assumed that the population had remained in a nearly stationary state during that time—an assumption which affords the means of determining the ratio of the number who die at each age to the number who entered upon that age; for it is evident that in a place so circumstanced, and supposing also there is no migration, the number who survive or complete any year of age within a given period is equal to the sum of the deaths at all the greater ages during the same period. For the sake of facilitating calculations from the table, he reduced the numbers proportionally to 1,000, by which number he represented the infants of one year of age.

This method of determining the mortality from the mortuary registers, or *bills of mortality*, has been frequently adopted, particularly by Dr. Smart, in the formation of a table showing the mortality in the city of London about the middle of the last century; by St. Maur, in respect of Paris; and by Dr. Price for the celebrated Northampton table, presently to be described. But it is evident that as the population of a large town or district of country can never be absolutely stationary, and as migration must be constantly taking place to a greater or less extent, the method is not absolutely correct; and, in fact, the results to which it leads must be attended with great uncertainty. In order to obtain accurate results, it is necessary to know the numbers who actually enter upon each year of age, as well as the numbers who die in that age, during the period included in the observation; and hence, in addition to the mortuary register, an enumeration in each year, or at short intervals, of the community in the several ages of life, is requisite for the accurate solution of the problem. But, although great attention has been given of late years to the statistics of life, in various countries of Europe, it is only in a very few instances that sufficiently accurate data for the construction of a mortality table have been obtained from observations embracing indiscriminately all the different classes of the inhabitants. Of these few, the principal (if not the only) instances are the observations made in Sweden and Norway

MORTALITY

those of Dr. Heysham, at Carlisle; and more recently by Dr. Cleland, at Glasgow. With these may be noticed Hodgson's *Observations on the Duration of Life amongst the Clergy of England and Wales, extending over a Period of 100 Years, each Life being separately traced* (1864).

In consequence of the migration which is constantly going on among the inhabitants, it is very difficult to obtain with certainty the data necessary for determining the mortality of any town or district; but there are various associations of individuals with respect to which precise data exist. Such, for example, are the religious houses in Catholic countries; the tontines which were established in different countries of Europe during the last century; the annuitants of the British government; and especially the life assurance companies, now become so numerous. In all such associations, the numbers who enter upon and die in each year of age can be ascertained with precision from the records of the association, which, therefore, afford the data requisite for determining the rate of mortality at the different ages, without hypothesis of any kind. Tables were thus constructed by Kersseboom, from Dutch registers of annuitants; by De Parcieux, from the lists of the nominees in the French tontines, chiefly of 1689 and 1696, and from the mortuary registers of the Benedictines, and of the nuns in several convents in Paris; and by Mr. Finlaison, from six different classes of annuitants in English and Irish tontines. Of the assurance offices, the Equitable Society and the Amicable Society have published their experience separately; and in 1843 a series of tables was published under the superintendence of a committee of actuaries, exhibiting the law of mortality deduced from the combined experience of seventeen offices, including the two above named.

We shall now give a comparative view of the mean duration of life at the different ages, computed from some of the best known tables, premising a short account of each table.

1. *Northampton Table*.—This table, which in this country is perhaps better known than any other, on account of its having been adopted by the greater number of the assurance offices as the basis of their tables of premiums, was constructed by Dr. Price, from the bills of mortality from 1735 to 1780 of the parish of All Saints, in the city of Northampton. It cannot be considered as possessing much authority, either on account of the accuracy of the data, or the number of lives of which it embraces the history; and the hypotheses made use of in its formation—namely, that the number of inhabitants and the number of annual deaths remained the same during the forty-six years included in the observations, and also that the migrations all took place at the age of twenty years, so far tend to reduce its value that at the present time only some twelve or thirteen offices retain it as the basis of their tables. It differs from the modern tables in

giving a much lower expectation of life at the younger and middle ages; a circumstance which may be in part owing to the improved condition of the labouring classes of the people, but probably in a much greater degree to the inaccuracy of the observations. (Price *On Reversionary Payments*, 4th ed. 1783.)

2. *Carlisle Table*.—This was constructed by Mr. Milne, from registers kept by Dr. Heysham of the births and deaths which took place in the parishes of St. Mary and St. Cuthbert, Carlisle, in the nine years from 1779 to 1787, the number of inhabitants having been determined by two enumerations which were made during that interval. On account of the accuracy of the data, and the skilful manner in which they were made use of, this table is of considerable authority, though it probably gives a somewhat too favourable view of the duration of life as experienced among the inhabitants of England generally. (Milne's *Treatise on Annuities*, &c. 1815.)

3. *Government Tables*.—These tables, as already mentioned, were computed by Mr. Finlaison, from observations of the mortality among the nominees of life annuities granted by the British government. Mr. Finlaison has given twenty-one tables of the probabilities of life; but the recorded facts are contained in only six of them, the others being formed by combinations of these six. (Finlaison's *Report to the Lords of the Treasury*, published by order of the House of Commons, 1829.)

4. *Equitable Society's Table*.—This table, which was originally framed by Mr. Griffith Davies from decrements of life amongst its members, and more fully drawn out by Mr. Arthur Morgan from more complete data, exhibits the mortality which took place in the society from its establishment in 1760 to the end of the year 1829. By reason of the great number of lives contained in it, and the certainty of the data, this is a document of great importance. It will be seen from the subjoined table, that, for ages under fifty, it gives a rather more favourable expectation of life than the government table for males, and agrees nearly with the Carlisle table; but for ages above fifty it gives a less favourable expectation than either of those tables. The observations commence at the age of ten.

5. *The English Life Table*.—This table is described and published in the *Fifth and Sixth Annual Reports of the Registrar-General* (1843 and 1846). It is constructed from the returns to parliament of the ages of the population of England in 1841 and of the deaths registered at different ages in that year, and is probably a close approximation to the mean duration of life in this country. Dr. Farr, of the Registrar-General's Office, has since published (1864) a *New English Life Table* from the returns of two censuses and 6,470,720 deaths registered in seventeen years.

For the sake of avoiding decimal points, the numbers in the subjoined table show the mean

MORTALITY

duration of life for ten individuals, or the number of years enjoyed by ten individuals collectively. In respect of a single individual, the mean duration of life is the tenth part of the number given in the table.

Age	Northampton	Carlisle	Government (Males)	Government (Females)	Equitable Society	English Life Table
0	252	287	502	555		411
5	408	513	489	542		500
10	398	488	456	511	483	474
15	365	450	418	472	450	437
20	354	415	384	440	417	403
25	309	379	359	408	381	370
30	283	343	332	376	345	337
35	287	310	303	343	309	304
40	231	276	270	311	274	271
45	205	245	238	278	239	239
50	180	211	203	244	204	206
55	156	176	172	208	170	172
60	132	143	144	173	139	140
65	109	118	116	140	111	112
70	86	92	92	110	87	88
75	65	70	71	85	66	67
80	48	55	49	65	48	51
85	34	41	31	48	34	38
90	24	33	20	28	26	28
95	8	35	12	16	11	20

There are many questions of great interest respecting the law of mortality which cannot yet be satisfactorily answered, from the want of sufficient data. The Carlisle table gives only an indication of local mortality; but it may be asked, whether the mortality is the same in different parts even of the same country, or the same in cities as in rural districts? Now, the government annuitants resided in all different parts of the kingdom; and the same may be said of the members of the Equitable Society, though, perhaps, a majority of the latter were resident in London. But the three tables—namely, the Carlisle table, the table computed from the government male annuitants, and the Equitable Society's table—present a remarkable agreement; and, so far as their evidence goes, we cannot draw any positive conclusion, either in favour of a particular district or a select class of individuals.

It seems to be established beyond doubt that the rate of mortality, at least in England, has undergone a very sensible diminution within a century, especially in respect of children and aged people. This may be ascribed in some degree to the discovery of vaccination; but more especially to the general diffusion of comfort, and the improved mode of living, among the labouring classes of the community.

Another question of great importance is, whether the law of mortality is the same for both sexes? In the above table it will be seen that there is a remarkable disparity between the male and female annuitants in favour of the latter. This indication of the greater longevity of females is confirmed by the observations of De Parcieux on the monks and nuns in the French convents; of Kerseboom, on the Dutch annuitants; of Dr. Price, on the mortality at Chester; and also by the tables con-

MORTGAGE

structed from the mortality in Sweden, at Montpelier in France, and in the cities of Amsterdam and Brussels. It is still, however, open to doubt whether the superiority shown in the above instances holds generally true. In the whole population of Belgium, the greater part consisting of peasantry and labourers, it is found that the lives of females are shorter than those of males; while in the towns the advantage is on the side of the females. The combined experience of the seventeen life assurance offices above referred to shows no superiority in the duration of female life.

The following table, showing the proportion of deaths to the population in the principal states of Europe, according to the latest observations, is extracted from a paper in the *Revue Encyclopédique* for July and August, 1833. We cannot vouch for its accuracy, but it is probably not far from the truth.

Countries	Periods or Epochs	Ratio of Mortality to Population
Sweden and Norway	1821—1825	1 in 47
Denmark	1819	1 in 45
European Russia	1826	1 in 44
Kingdom of Poland	1829	1 in 44
British Islands	1818—1821	1 in 55
Netherlands	1827—1828	1 in 58
Germany Proper	1825—1828	1 in 45
Prussia	1821—1826	1 in 59
Austrian Empire	1828	1 in 40
France	1825—1827	1 in 39
Switzerland	1827—1828	1 in 49
Portugal	1815—1819	1 in 40
Spain	1801—1826	1 in 40
Italy	1822—1828	1 in 30
Greece	1828	1 in 80
Turkey in Europe	1828	1 in 30
Northern Europe		1 in 44
Southern Europe		1 in 34
The whole of Europe		1 in 40

For an accurate description of the various mortality tables up to the date of its publication, the reader is referred to the excellent article on the subject, by Mr. Milne, in the *Encyclopedia Britannica*, 8th edition.

MORTAR. [CEMENTS.]

MORTAR. In Artillery, a short piece of ordnance, used to throw shells at very high angles (vertical fire), generally 45°, the charge varying with the range required. Mortars are distinguished by the diameters of their bores. They are not mounted on carriages, but on simple beds of wood or iron.

Mortar Vessel. A small vessel of considerable beam, for carrying a heavy mortar amidships, which is slung in a massive bed. The mortar vessels were formerly known as *bomb ketches*.

Mortgage (Fr. from *mort*, *dead*, and *gage*, *pledge*). In Law, a mortgage deed is in effect an absolute conveyance from the borrower to the lender, with a condition that if a sum of money is paid by a stipulated day the property shall be reconveyed. Thus the grantee has a conditional estate, during the continuance of which the mortgagor, though in possession, is

MORTIER

in contemplation of law only tenant at will to the mortgagee; and on failure of payment, the estate of the mortgagee would become absolute at law. But in equity the mortgagee's estate is subject to an *equity of redemption*, or right to redeem on the part of the mortgagor; and a mortgage is thus redeemable so long as the relation of debtor and creditor appears to subsist between the parties, and for twenty years after the last acknowledgement of that relation by the mortgagee, unless upon his application the right be previously foreclosed by a decree of the court. Mortgages now commonly contain a power authorising the mortgagee to sell the property and repay himself out of the proceeds.

Mortier (Fr.). The name given to a cap of state, of great antiquity, worn by the first kings of France, and the form of which is still preserved in the cap worn by the president *de la cour* of Paris.

Mortification (Lat. *mortificus*, causing death). Local death; gangrene. When any portion of the body loses its vitality, a process of separation takes place between it and the living parts that surround it; and when this happens in certain parts or organs it is necessarily fatal. The symptoms attending mortification of the viscera are generally loss of pain, diminution of fever, small sinking pulse, hiccup, delirium, cold sweat, and fainting, which precedes death.

MORTIFICATION. In Scottish Law, a term nearly synonymous with mortmain in English. By an Act of 1587, land vested in the church was declared to be given for superstitious purposes, and to belong to the crown; and thus the spoliation of the richly endowed church of that country prior to the Reformation was finally legalised.

Mortise (Fr. *mortaise*, from Lat. *mordere*, to bite). In Architecture, a mortise is the junction of two pieces of wood, or other material, the cavity being cut in one piece to receive the projection left in the other, which is called the tenon or tenant.

Mortmain (Old Fr.). In Law, an alienation of lands, tenements, or hereditaments, to any corporation, sole or aggregate, guild, or fraternity. The foundation of the statute of mortmain is Magna Charta, by which it was rendered unlawful for anyone to give his lands to a religious house, &c. in order to take them back again to hold of the same house; which was extended, by interpretation, so as to annul gifts of lands which religious houses did not give back to the donor to his own use, but kept in their own hands after taking. A great number of statutes were afterwards passed in order to restrict alienations to religious persons and houses, and various devices formed for the purpose of eluding them; of which the system of uses, which has become in some sort the foundation of our law of real property, was one. [REAL PROPERTY; TRUST.] But during the whole of

MOSAIC

this time the king had the power of dispensing with the statutes of mortmain by granting licenses of alienation; and this power was confirmed to the crown by stat. 7 & 8 Wm. III. c. 37. Gifts for charitable purposes are now subjected, by the Mortmain Act of 9 Geo. II. c. 36, to particular restrictions, a neglect of which frequently invalidates them. The term *mortmain* is derived from the Latin words *mortuus manus* (*dead hand*), because the lands so alienated are said to fall into a dead hand; i.e. one incapable of performing the usual services required of tenants.

Mortuary (Lat. *mortuarius*, belonging to the dead). In Law, a fee paid to the incumbent of a parish, by custom peculiar to some places, on the death of a parishioner. It appears to have been a very ancient usage to present the priest, on the solemnisation of a funeral, with some personal chattel of the deceased, or a sum of money in lieu of it; under the various titles of *pecunia sepulchralis*, *sedatium*, in Saxon *soul-shot*, &c. It had become a legal custom as early as the reign of Henry III., when the reservation of a mortuary appears to have been essential to the validity of a testament of chattels. The amount was fixed by 21 Henry VIII. c. 6, according to an *ad valorem* taxation of the goods of the deceased. Mortuaries (where due by custom) are recoverable in the ecclesiastical courts; and it should appear, since the statute, at common law; although such actions have not hitherto been brought.

Morus (Lat.; Gr. *μύρος*, the mulberry-tree). A small genus of plants belonging to the *Moraceæ*, containing some species valuable for their fruit, and others for their foliage. The former is our Mulberry-tree, *Morus nigra*, whose well-known black juicy berries are a favourite autumn production; the latter are *M. alba* and others, which constitute the best of all food for silkworms, but are somewhat tender in our climate, and cannot be usefully cultivated even in the midland country of England.

Morvenite. A variety of Harmotome, found in the granite of Strontian in Argyllshire.

Mosaic or **Musale** (Lat. *musivus*). In Painting, representations of objects by means of very minute pieces of stones or pebbles of different colours, or variegated glass carefully inlaid upon a ground generally of metal, are known by this name. This art was practised at a very early period, and was reintroduced to Italy by the Byzantine Greeks. It was applied by the Romans in four different styles: the *opus tessellatum*, the *opus vermiculatum*, the *opus sectile*, and the *opus musivum*. The first three are purely geometric or ornamental, and are strictly only *opus lithostroton*, i.e. the regular mechanical arrangement of various coloured stones, sometimes in small cubes called tesserae or tessellæ, sometimes in slabs of various shapes. The *opus musivum* was the only pictorial mosaic, i.e. in which natural objects were imitated.

MOSAIC GOLD

Mosaic Gold. Bisulphide of tin; a yellow flaky substance, sometimes employed in ornamental japan work. This term has also been applied to a superior kind of brass, and to a yellow alloy of copper, zinc, and gold. [AURUM MURVUM.]

Mosaic Work. In Architecture, the inlaying pavements, walls, &c. with small dies of different-coloured stones or glass, in regular figures, or to represent historical or other subjects.

saurus (Lat. *Mosa, the Meuse*, and Gr. *σαῦρος, lizard*). A large extinct Lacertian reptile which existed during the deposition of the Cretaceous strata. Its remains have been found both near Maestricht and in the cretaceous deposits in America. The concave-convex or procelian type of vertebrae existed in the spinal column of this extinct gigantic saurian.

Moslem. [MUSSULMAN.]

Mosque (Arab. *medschad*). A Mohammedan place of religious worship. The principal interior decoration of mosques consists in the lamps, which are numerous, and singularly disposed; the floor is covered with carpets: the direction of Mecca is denoted by a niche, or by a tablet inscribed with verses of the Koran, called the *Kebla*. The principal Arabian and Syrian mosques are most remarkable for their vast quadrangles, surrounded with numerous columns; those of the Turks for the elegance of their cupolas. The original places of worship of the Arabians were the temples dedicated to the religion of the different nations whom they subdued. It was not until they had consolidated their power that the Arabians devoted themselves to the cultivation of the arts, and gave any indication of that architectural genius which afterwards displayed itself in the structure of mosques. At the entrance of almost every mosque there is a large court planted with bushy trees, in the centre of which, or under a vestibule paved with marble, are fountains for the prescribed ablutions of the Mussulmans; and to these courts is usually attached a small gallery, on which the apartments of the ministers of religion, &c. abut. But besides mosques for public worship, there are others set apart for the instruction of young men in the science of legislation and the doctrines of the Koran; and to this class belong the so-called *royal* mosques, or *jamie*, of Constantinople. Most of these mosques have hospitals for poor, sick, or deranged persons, attached to them. Their revenues are often considerable, and are derived chiefly from endowments in landed property. The term *mosque* is found, with slight variation, in all European languages. The Turkish equivalent is supposed to be derived from the Arabic *mejad*, a *place of adoration*; and from this are derived respectively the French *mosquée*, the German *moschee*, the Spanish *mequita*, the Italian *mascheta*, and the English *mosque*. [MINARET.]

Mosquito. The American name for the species of gnat *Culex*. They abound in damp

MOTET

situations, both in the warmer climates and during the summer months in high northern latitudes. They pierce the skin with a lancetted proboscis, and discharge a venomous liquor into the wound; they can be guarded against at night by enclosing the bed with a mosquito curtain. The Laplanders drive them away by fire, and by coating the naked parts of the body with grease.

Moss Agate. The name given to those kinds of Agate which enclose dendritic or moss-like markings. They are found in large quantities at Oberstein in Saxony.

Moss Land. Land abounding in peat moss, but not so much saturated with water as to become peat bog, or morass.

Mosses (Fr. *moissee*, Lat. *muscus*, Ger. *moos*). In common language, mosses signify any minute, small-leaved Cryptogamic plants. But in systematical botany no plants are considered mosses, except such as belong to the natural order *Bryaceae* or *Musci*. Such plants are simple-leaved; without spiral vessels or stomates; with a distinct axis of growth; and with the spores or reproductive matter enclosed in cases, called *sporangia* or *theca*, covered by a cup or calyptra. The structure of the sporangia is as complex as that of the stems and leaves is simple. Each sporangium is closed by a lid or operculum; below which is a transverse membrane, closing up the urn left after the fall of the operculum. The edge of the urn is furnished with one or more rows of teeth, in all cases some multiple of four; in the centre is a columella or column, and between the latter and the sides of the urn are the spores. It is not a little singular that such plants should have cases called *staminidia*, containing powdery matter; among which are found animalcules, not distinguishable from such as are called spermatic, and which swim about freely in water.

Moss-troopers. In English and Scottish History, those inhabitants of the borders of the respective countries who were banded together in clans and lived by rapine, received this denomination from the character of the country over which they *trooped* in their excursions. These banditti were little heard of after the union of the two crowns, but not absolutely suppressed until the union of the kingdoms a century afterwards.

Mossotite. A variety of Aragonite, found in the Lias of Gersfaleo in Tuscany.

Motachettes. [SEPARATIONS.]

Mote. Among the Anglo-Saxons, public courts or convocations of the people assembled for municipal or legislative purposes were of various kinds; as *Moot*, *Folk-mote*, *Borow Mote*, &c. *Mote* was a customary service or payment at the mote or court of the lord, from which certain persons alone were exempted by charter or other privilege.

Motet (Ital. *motetto*). In Music, a vocal composition, consisting of from one to eight parts, of a sacred character.

MOTHER LIQUOR

Mother or Mother Water. A term applied by chemists to saline solutions from which crystals have been deposited, and which, when poured off and re-evaporated, generally furnish a second crop.

Mother of Pearl (Ger. *perlen-mutter*, Fr. *nacre de perles*). The hard, silvery, brilliant internal layer of several kinds of shells, particularly oysters, which is often variegated with changing purple and azure colours. The large oysters of the Indian seas alone secrete this coat of sufficient thickness to render their shells available for the purposes of manufactures. The genus of shell fish called *Pentadina* furnishes the finest pearls, as well as mother of pearl; it is found in greatest perfection round the coasts of Ceylon, near Ormus in the Persian Gulf, at Cape Comorin, and among some of the Australian seas. The brilliant hues of mother of pearl do not depend upon the nature of the substance, but upon its structure. The microscopic wrinkles or furrows which run across the surface of every alioe act upon the reflected light in such a way as to produce the chromatic effect; for Sir David Brewster has shown that if we take, with very fine black wax, or with the so-called fusible alloy, an impression of mother of pearl, it will possess the iridescent appearance. Mother of pearl is very delicate to work; but it may be fashioned by saws, files, and drills, with the aid sometimes of an acid, such as the dilute muriatic; it is polished by colcothar. (*Ure's Dictionary of Arts, &c.*)

Mother of Vinegar. The flocculent mycelium of various Moulds, which forms on the surface of vinegar.

Mother-cells. In Vegetable Physiology, cells in which other cells are generated.

Motion (Lat. *motio*). In Mechanical Philosophy, motion is change of place: i.e. of the part of space which body occupies, or in which it is extended. Motion is *real* or *absolute* when the moving body changes its place in absolute space; it is *relative* when the body changes its place only with relation to surrounding bodies; and it is *apparent* when the body changes its situation with respect to other bodies that appear to us to be at rest. All the phenomena of motion are derived by mathematical deductions from the three following *laws of motion* given by Newton in his *Principia*:—

1. A body must continue for ever in a state of rest, or of uniform motion in a straight line, if it be not disturbed by the action of an external cause.

2. Every change of motion produced by any external force is proportional to the force impressed, and in the direction of the straight line in which the force acts.

3. Action and reaction are equal and in contrary directions; that is, equal and contrary changes of motion are produced on bodies which mutually act on each other.

The term *quantity of motion* is used, by writers on mechanics, to denote the product

MOULD

of the mass of a body into the velocity with which it moves. It is, therefore, synonymous with *momentum*.

Motion. In Music, refers to the movement of the parts in contrapuntal writing. Direct or similar motion is when two parts move in the same direction, i.e. rise or fall together; contrary motion is when one rises and the other falls; and oblique motion is when one part moves in either direction while the other is stationary. Contrary motion is the best, and next oblique motion.

Motion. In Painting and Sculpture, the change of place or position which from certain attitudes a figure seems to be making in its representation in a picture. It can be only implied from the attitude which prepares the animal for the given change, and differs from *Action* [which see]. Upon motion, in art, depends that life which seems to pervade a picture when executed by a master.

Motion in Court. In Law, an occasional application to the court, by the parties or their counsel. *Motions* are either of a criminal nature, as *motions for an attachment* for a misbehaviour; or of a civil nature. A motion in the courts of common law is either for a rule absolute, i.e. to take effect immediately; or it is for what is termed a rule nisi, or a rule to show cause—i.e. a rule to take effect, unless cause be shown against it by a certain day, when, if no cause be shown, the rule is made absolute. *Motions* also form an important part of the practice of courts of equity. *Injunctions* [*Injunction*] are usually applied for in this manner. *Motions* are accompanied by affidavits stating the facts on which they are grounded, and generally preceded by a notice to the opposite party.

Motory or Motorial. In Physiology, this term was applied by Hartley, in 1749, to the nerves conveying the stimulus to the muscles, in contradistinction to the nerves conveying the impressions to the neural axis, which he called *sensory*; but he distinguished those actions which result from the conveyance of impressions to the brain, producing sensation and exciting volition, from those actions which are now called *reflex*; as where he states that 'the actions of sneezing, swallowing, coughing, hiccoughing, vomiting, and expelling the feces and urine, with others of a like nature, are to be deduced from those vibrations which first ascend up the *sensory* nerves, and then are detached down the *motory* nerves, which communicate with these by some common trunk, plexus, or ganglion.'

Motto (Ital.). A term used to signify a word or sentence added to a device; when put upon a scroll, it is commonly employed as an external ornament of coat armour. The use of mottoes for this purpose is very ancient. The term *motto* is also applied to a sentence or quotation prefixed to any writing or publication.

Mould (Goth. *mulda, dust*). Soil composed of decayed vegetable matter in a state of minute division, more or less mixed with gar-

MOULD

den earth. The kinds of mould most in use in horticulture are Leaf mould, formed from the decayed leaves of trees; Rich mould, formed of thoroughly decayed stable dung; Heath mould, found on the surface of heath lands; and Peat mould, formed of thoroughly decomposed peat. In general, mould is distinguished from soils by containing a much greater portion of organic than of earthy matters.

Mould (Fr. moule; Span. molde; probably from Lat. modulus). In Sculpture, the matrix or hollowed wrought form into which the liquid or plaster, wax or metal, is run in casting works of art.

A *safe-mould* is a mould taken in many pieces from the original cast from the first mould, which is destroyed, so that it can be safely removed from the model, and be put together again, in order to produce other casts.

Mould Loft. A large room in a dockyard in which the several parts of the ship are drawn out in their proper dimensions, for the guidance of the builder.

Moulds. This name is popularly applied to the thread-like *Fungi* which prey upon our provisions, and attack such substances as gum, glue, ink, &c., living at their expense, and destroying their valuable properties. Many of the moulds, observes Mr. Berkeley, are capable of sustaining life when immersed in fluids, contrary to the habit of most *Fungi*; and from their capability of appropriating what is nutritious, and rejecting what is hurtful, they are often developed even in solutions of poisonous metallic salts, which would be fatal to *Fungi* in general. In a solution of sulphate of copper, for example, they become as it were electrotyped by the copper, while they appropriate the other elements.

As the spores are often able to sustain a considerable degree of heat without destruction, they occur in situations where they would otherwise not be expected, as in preserved fruits which have been subjected to heat, and when there could be no access of fresh spores. Where there is any possibility of communication, there are few kinds of vegetable tissues which they cannot penetrate; and in animals, they occur in situations where they must, like intestinal worms, have worked their way through the tissues to the cavities in which they grow. They are amongst the most destructive agents in the production of disease, as is proved by the potato murrain. In the human frame they are the fruitful source of cutaneous disorders. (Lindley and Moore, *Treasury of Botany*.)

Moulding (Fr. moulure). In Architecture, the various members of an order, which are shaped into various curved or flat forms, of which there are eight sorts: (1) the fillet, square in profile; (2) the astragal; (3) the torus, larger than the astragal; (4) the scotia; (5) the echinus or quarter round; (6) the inverted cyma, talon, or ogee; (7) the cyma, the cyma recta, or cymatium; and (8) the cavetto or hollow.

MOUNTAIN LIMESTONE

In the Romanesque, and Teutonic or Gothic styles of architecture, mouldings are of great importance, as determining the exact stage of art to which a particular building belongs. (F. A. Paley, *Manual of Gothic Mouldings*.)

Moulting. The fall of the plumage of birds. It may be either partial or total. The complete moult generally takes place annually; the partial moult occurs at the change of plumage to which some species of birds are subject at the breeding season. The moult is always accompanied by the development of a new plumage, which may be of a different colour from that which is lost. [INDUMENTUM.]

Mountain (La Montagne). In French History, a popular name given in 1793 to the party of extreme Jacobins in the Convention, who occupied the highest rows of seats, while the moderate men generally crowded into the lower places in the centre (thence called *plain*). As government fell more and more into the hands of these violent politicians, it became in course of time a title of honour, and (after the fall of Robespierre) of reproach.

Mountain Blue. Blue copper-ore. [CHESYLITE.]

Mountain Cork. [ASBESTOS.]

Mountain Green. [CHRYSOCELLA.]

Mountain Leather. A variety of Asbestos occurring in flat flexible pieces resembling leather, and of a whitish colour. It differs from common Asbestos chiefly in having the fibres interlaced instead of even and parallel.

Mountain Limestone. The rock thus named is often called the *carboniferous limestone*, but to English geologists the older name will always be interesting, as marking some of its essential peculiarities in England.

This kind of limestone is of various colours, and often so full of organic remains as to appear almost entirely made up of them, especially of fragments of encrinural columns; but sometimes scarcely an organism is to be detected, and the rock is veined and variegated with streaks of calcareous spar. Both these varieties form useful and often handsome marbles.

This rock is of further interest, as being that which in the centre and north of England is the seat of our most productive lead mines; hence it is called *metalliferous limestone*. The great patch of limestone extending from the Tweed to the Tees, bounded by the coal measures on the east, and on the west by the Cheviot Hills, is especially known as the *lead measures*. The characters of the rocks are very variable. The veins hitherto worked occupy a space of about fifteen miles north and south, and twenty west and east, and run, with little exception, nearly west and east.

The Yorkshire limestone district, exclusive of its metallic veins, is traversed by others, which, as they are only filled with non-metallic minerals, are of little interest to the miner, although of deep importance to the geologist. They intersect the metallic veins, disturbing the parallelism of the strata, and often occasioning

MOUNTAIN LIMESTONE

much irregularity and confusion. The contents of these cross-courses are very miscellaneous; and where the material with which they are filled is much harder and more durable than the regular strata, their course is often perceptible upon the weather-worn surface of the country which they traverse. Such is the cross-vein of the lead measures called the Devil's Backbone, forming a ridge that may be traced a considerable distance along the country through which it passes.

The Derbyshire limestone district is well known. Castleton is its northern point, and it extends southward about twenty-five miles to Weaver Hill. Its breadth is very irregular, but nowhere much exceeds twenty miles. At its eastern end it produces the delightful and varied scenery of Matlock, and its north-western extremity is celebrated for the wonders of the Peak.

In regard to the varied aspect of this district, it may be observed that the different strata of limestone differ considerably from each other; that beds and dikes of basalt intervene, provincially called *toadstone* (todd-stein, *dead or unproductive rock*); and lastly, that the country is traversed by great faults or dislocations.

The singular turreted and broken appearance of these limestone rocks, and the fantastic shapes which their various masses occasionally assume, are well seen in Dovedale; and some of their other peculiarities, especially their curvatures, and some of the dislocations which they have suffered, are evident in Matlock and its neighbourhood. In the High Tor the stratification appears horizontal and regular when viewed in front; but a more accurate examination shows that it is curved and irregular. An instance of curved strata may be seen in Crich Cliff, about four miles east of Matlock; it is an isolated hill about 900 feet above the level of the river. The different beds of limestone are of very different qualities and composition; the upper cherty, and often bituminous, abounding in corallines and encrinurid stems, &c., often curiously seen in relief upon its weather-worn surface. Beneath the rock, beds of magnesian limestone and silicious limestone or dunstone are seen, and towards the lower part beds of black marble. The lowest limestone stratum is that which forms the Peak Forest, the downs of Buxton, and the Weaver Hills; and in it are several remarkable caverns. We find at Castleton numerous veins of fluor spar, used in the manufacture of glass, &c.; also elastic bitumen, or fossil asphaltum. The subterranean streams which traverse many of these caverns, the stalactites and stalagmites in which they abound, and the thermal waters which characterise the district, are all important points to be noticed. The toadstone of Derbyshire is sometimes regularly stratified between the limestone beds. The toadstone never contains shells or organic remains; chalcedony, zeolite, and globules of calcareous spar are not uncommon in it. In the cave at Castleton it forms a large irregular column.

MOUNTAIN SYSTEMS

The veins of the limestone in Derbyshire contain ores of lead, manganese, copper, zinc, and iron: indeed, the proper repository of the lead appears to be the limestone, though it also occurs in some other strata, and rarely in the toadstone, in which it is always in small quantities, and merely in strings or very imperfect veins.

Near Bristol the limestone hills rise from below the new red sandstone, and from the edges of the coal basin. In some places it is very bituminous, as on the Avon at Chepstow, where it exudes petroleum. On the Welsh coast of the Bristol Channel we have another ridge of limestone, forming one side of the basin in which the great coalfield of South Wales is situated. The hills on the west of Swansea and the cliffs on the south of Pembroke are of this formation; and on the banks of the Wye it constitutes scenery of a soft but most romantic character. There is something singularly fascinating in the landscape of the limestone districts, resulting not only from the varied forms and groupings of the mountain masses, but depending also upon the nature of the substance and of the soil derived from its decay. Upon the perpendicular and projecting precipices lichens of various and singular hues alternate with the grey surface of the uncovered rock; a variety of shrubs are scattered by nature's hand upon its picturesque and waving sides; ivy and other creeping plants issue in gay luxuriance from its crevices, and the glens and valleys are adorned by every variety of verdure. [CARBONIFEROUS SYSTEM.]

Mountain Systems. In all countries the mountains are singularly influential in modifying the essential features of the land, in influencing climate, and in governing the distribution of life. There is nothing in physical geography that affords a better indication of the present condition and future capabilities of a country than its mountain and river systems.

Mountains occur usually in lines of considerable length, as compared with their breadth. A mountain chain is thus a continuous series of elevated land, broken occasionally by valleys, and rising here and there into lofty peaks. When the phenomenon is on a grand scale, the chain influences greatly the geological structure; and when local, there is local geological cause.

Each great tract of the earth has its mountain system, governing its form and often marking its outline. In some countries where there are many such chains having different directions, the older mark the coasts, and the newer the central ridge. In others the coast range is the principal and more modern elevation, and determines the whole character of the interior.

The principal mountain chains of the earth are as follows, and are noticed under separate headings. In Europe and Asia, including North Africa, a vast central line of chief elevation includes the HIMALAYAN chain, the CAUCASUS, the ALPS, the ATLAS, and the PYRENEES. Somewhat subordinate to these, but still important, are the

MOURNING

CARPATIANS, the **BALKAN**, and the **APENNINES**. In South Africa there is no principal mountain chain. In America there are the **ANDRES** and the **ROCKY MOUNTAINS**, and the much lower, but not unimportant, chain of the **APPALACHIANS**.

Volcanoes do not form mountain chains, though they occasionally occur in continuous lines. Besides the continuous chains and detached volcanic mountains, there are not wanting instances of isolated mountain masses.

Many of the great mountain chains are continued beyond the coast into the ocean as submarine mountains. There can be little doubt that these phenomena mark great lines of upheaval, and are very important in reference to the earth's history.

Mourning (akin to Gael. *mairgnich*, to grieve; Gr. *μερῦναι*, to be anxious; Goth. *maurnan*; Wedgwood). Any external indication or manifestation of grief for the death of a friend or relative. Certain usages in regard to mourning have been in force among all nations from the earliest ages; but except in the grief of which they are intended to be the symbol, no customs exhibit fewer marks of uniformity. Thus, the Chinese mourn in white; the Turks in blue or in violet; the Egyptians in yellow; the Ethiopians in grey. In ancient Rome and Lacedæmon the ladies mourned in white. In Eastern countries it was regarded as a peculiar mark of affliction to cut the hair; and at Rome, on the contrary, to let it grow. The Greeks adopted the Eastern practice, and bestrewed with their hair the tombs of those for whom they mourned. The peculiarities of the ancient Jews in time of mourning are well known; and the various customs of which so minute an account is contained in the Pentateuch are still maintained on these occasions by their descendants. From the commencement of the Christian era the general colour adopted for mourning throughout Europe has been, with very few exceptions, black. The kings of France mourn in violet. The duration of the period of mourning differs in different countries, but in all is usually regulated by the nearness of relationship between the survivors and the deceased. The rules that determine the forms and duration of *court mourning* emanate from the sovereign, but do not extend beyond the court. (The art. 'Deuil,' in the *Encyclopédie des Gens du Monde*, gives a very complete view of the chief modes of mourning in use in ancient and modern times.) [SEPOLTURE, RITES OF.]

Mouse. In Naval Affairs, a hump or knot worked on a rope, to prevent a noose from slipping.

Mous. In Zoology. [Mus.]

Mousing a Hook. Passing a piece of spun yarn round the point and back of the hook of a block, in order to prevent its disengaging itself from anything it may be hooked to.

Mouth (Ger. *mund*, Goth. *munths*). In Architecture, the same as **CAVETTO** [which see].

Loveable Feasts. Certain festivals held in commemoration of different events recorded in the Gospels and the Acts of the Apostles.

MUCK, RUNNING A

As they are reckoned backward and forward from the Resurrection, and as the celebration of that event depends on the time of new moon, which varies at different times through the space of a month, these dependent festivals also vary in the same way. Easter is always the first Sunday after the first new moon after March 21; and from this all the others are reckoned for each year.

Movement. In Politics, an expression adopted of late years into the political vocabulary of most European nations, signifying that party in a state which strives to obtain such concessions in favour of popular rights as will ultimately place the chief functions of government in the hands of the people. It is opposed to the Conservative party, or the *parti de résistance*.

Moving or Motive Force. In Mechanics, the cause of the change of velocity in the motion of a body. At any instant it is measured by the increment of momentum, referred to the unit of time, and is, therefore, expressed by $m \frac{d}{dt} = m \frac{d^2s}{dt^2}$. The unit of moving force is that which in every unit of time could impart to the unit of mass a unit of velocity. That part of the moving force which may be conceived to be acting upon each unit of mass of a moving body is often called the accelerating force.

Moxa (Fr.). There are various substances used in surgery to produce a sore by means of slow combustion. Moxa, which is one of these substances, is prepared in Japan and China from certain species of *Artemisia*, as *A. Moxa*, *A. chinensis*, &c., and consists of the downy covering of their leaves and stems.

Mozambique Current. A south-westerly current thus named sets along the African coast toward the channel of Mozambique during the whole year, and is probably the result of a drift current produced in the South Indian Ocean by the monsoons; it varies much in different seasons and years. The set of the winds drives the water up among the islands, and forces it to recover its level by rushing through the Mozambique channel.

This current is a part of the chain conveying the waters of the Pacific to the Atlantic, and is connected with the current produced within a narrow belt of ocean on the south side of the equator. On the north side the causes act less regularly, and the results are not traceable.

Mucic Acid. A crystalline acid formed by the oxidation of gum arabic, sugar of milk, and other members of the saccharine group of substances. It is a dibasic acid.

Mucivora (Lat. *mucus*; voro, *I devour*). A name applied to a family of Dipterous insects, comprehending those which feed on the juices of plants.

Muck, Running a. A phrase which has been adopted into the English language to signify an indiscriminate attack upon friends and enemies; as in the verse,

MUCOUS MEMBRANE

Who runs a smok, and tilts at all be mests.

This expression is derived from the Javan word *amok*, which means *to kill*; the inhabitants of Java, and many other of the Asiatic islands, being remarkable for a frenzy which leads them to aim at indiscriminate destruction. These fits of desperation were long considered peculiar to the class of slaves in the islands above mentioned; but there are many instances on record where whole villages, and even armies, have under the influence of *amok* devoted themselves to destruction to avenge an injury or an insult. The accounts of the wars of the Javans, says Raffles, in his *History of Java*, as well as of the Malays, abound with instances of warriors running *amok*; of combatants rushing on the enemy, committing indiscriminate slaughter, and never surrendering themselves alive. The cause of these fits of desperation has been attributed to intemperate opium-eating.

Mucous Membrane. The membranous lining of the canals and cavities of the body which are exposed to the contact of air or other inorganic substances. The basis of this membrane is compact cellular tissue, having a peculiar cuticular covering, beset in some cases with abundant nervous papillæ in others with the orifices of secretory glands.

Mucronate (Lat. *mucronatus*, from *mucro*, a point). In Botany, applied to any organ which is abruptly terminated by a hard sharp point.

Mucuna (*Mucuna-guaca*, the Brazilian name of one of the species). The genus of Leguminous plants which yields the Cowage or Cow-itch of the *Materia Medica*. The species is *M. pruriens*, a tall West Indian climber, bearing thick leathery pods, which afford the Cowage, a celebrated remedy for intestinal worms. The pods are shaped like the letter *f*, four or five inches long, and clothed with short stiff brittle brown hairs which cause intolerable itching. Their beneficial effect is attributed to the action of the irritating hairs on the worms.

Mucus (Lat.). The secretion of the mucous membranes, the most characteristic of which is that from the nasal membrane. Mucus is viscid, and acquires apparent fluidity in water, without being actually dissolved. It may be repeatedly dried and moistened without material change of properties. When boiled in water it becomes tough, but on cooling resumes its former characters. When dried, it is yellowish and translucent. It is precipitated from its aqueous mixture by acetic acid and by alcohol. Under the microscope it presents nucleated globules and epithelial scales, which vary in appearance according to the situation and functions of the particular membrane from which they have been thrown off.

Mundar. The Indian name of *Calotropis gigantea*, a plant of the Asclepiadaceous order, used medicinally in the East Indies in scrofulous cases.

MULATTO

Muressin. In Mohammedan countries, the general appellation of those officers, or clerks of the mosques, whose duty it is to proclaim the summons to prayers, at the five canonical hours; viz. at dawn, noon, four o'clock P. M., sunset, and nightfall.

Muffle. An arched vessel with a flat bottom, in which substances may be exposed to a red heat without coming into contact with the fuel. [ASSAYING.]

Mufti. The Turkish title of a doctor of the law of the Koran; derived from *fetvas*, a rescript or answer to a question of law addressed to the competent authority; which *fetvas* it is the province of the mufti to issue. The mufti of Constantinople, or Sheikh-ul-Islam, is the chief functionary of the Turkish church, and represents the sultan in spiritual matters, as the grand vizier does in temporal.

Muggletonians. A sect of Christians who sprang up in England in 1661, and derived their name from one Muggleton, a tailor, who, together with an associate called Reeves, gave themselves out as the two last and greatest prophets of Jesus Christ, and asserted that they had power to save or to ruin in a future state whomsoever they pleased. Notwithstanding the absurdity of their pretensions they obtained many adherents; and the belief in their inspiration has been maintained by a small number down to the present time. A collection of the writings of Muggleton and Reeves, together with other Muggletonian tracts, was published in 3 vols. 4to. in 1832. In the religious controversy to which the promulgation of their doctrines gave rise, their chief opponents were the Quakers, and among these were George Fox and William Penn.

Mugiloids (Lat. *mugil*, a mullet). A family of Acanthopterygian fishes in the system of Cuvier, characterised by having an almost cylindrical body covered with large scales, and furnished with two separate dorsals, the first of which has but four spinous rays. The mouth is either edentulous, or is provided with teeth of extremely minute size. This family includes the genera *Mugil*, *Tetragonurus*, and *Atherina*; it is included in the Cycloid order in the system of Agassiz.

Mulatto. A term in general use in American countries (in which there exists a mixed population of different races and colours) for the offspring of a union between a white and a negro.

In our West Indian possessions the offspring of a white and a mulatto is called a *quadroon*, or one-quarter black; of a white and quadroon a *mustee*, or one-eighth black; of a white and mustee a *mustafina*, or one-sixteenth black; after which they are said to be *whitewashed*, and are considered as Europeans. On the other hand, the offspring of a mulatto and a negro is called a *cabre*; of a cabre and negro, a *griffe*; and, generally speaking, after this there is no distinctive appellation but *negro*. All this is sufficiently simple; but in the Spanish

MULBERRY

and Portuguese colonial possessions, the intermixture of Europeans with negroes, mulattoes, &c., and these again with other classes, has given rise to a multiplicity of denominations sufficiently vague and indefinite even in these languages, but wholly untranslatable into English. It must be admitted, however, that great ingenuity has been displayed in tracing the amount of European and negro blood that flows in the veins of the mixed races, as the following list of terms (which might be considerably augmented) will prove: *Zambi*, *quatralvi*, *tresalvi*, *salatras*, *coyote*, *zambaigi*, *cambusos*, *jiveros*, *puchuelas*, *albarassados*, *barrinos*, &c. All these again may be multiplied in arithmetical progression, thus forming a host of modifications, each, however, retaining more or less his original characteristics in proportion to the relation in which he stands to his original stock.

In Spain, the term *mulatto* has been employed to designate persons having a tincture of Moorish blood.

Mulberry (Ger. *maulbeere*, Lat. *morus*, Gr. *μῆρος*). The fruit of the *Morus nigra* and *Morus alba*. The so-called Paper Mulberry is the *Broussonetia papyrifera*; its tenacious pliable inner bark furnishes a valuable material for the dress of the South Sea Islanders and Chinese. [MORUS.]

Mulberry Calculus. A urinary concretion, consisting chiefly or entirely of oxalate of lime. Many of these calculi in form and colour somewhat resemble the fruit of the mulberry. [URINE.]

Mulch (Dutch *molsch*, akin to Latin *mollio* and *mulceo*, &c.). Straw or litter half rotten. In Horticulture, when this material is applied round the roots or stems of plants to protect them from the drought or from frost, they are said to be mulched.

Mule. A machine for spinning cotton. This very ingenious piece of mechanism was invented, about the year 1777, by Samuel Crompton, formerly of Hall-in-the-Wood, Lancashire. For many years the machine was worked by hand only, the variety of its movements rendering it difficult to accomplish the moving of it by the power of water or of steam so simply as to be of common use. (Buchanan's *Essays on Mill-work* 1841.)

MULE. In Botany. [HYBRID.]

MULE (Lat. *mulus*). In Zoology, the hybrid between the jackass and the mare; the hybrid between the stallion and the female ass being termed *hinny*. In most cases, the progeny either of mules inter se or with the parent stock is unfruitful, but a few instances in which progeny has been perpetuated have been observed. The Spanish mules are the progeny, on the sire's side, of a breed of asses far more strong and graceful than those existing in England. [HYBRID.]

Mull. A term used in Scotland almost synonymous with *Cape*; and applied to various projecting portions of the island, as the Mull of Galloway, of Cantyre, &c.

MULTIDENTATE

Mullas. The priests of Tartary are so called. They form one of the three grand classes into which the Tartars are divided; the other two being the *muras* or nobility, and the peasantry. Their chief duty consists in reading the Koran; but their stock of knowledge is generally so scanty, that they are seldom able to interpret the Arabic in which the office of the mosque is performed. The village mullas are generally decently behaved and respectable men; 'a little too much given to sell charms for the ague, but living for the most part among their neighbours a quiet and charitable life, the arbitrators as well as curates of their sequestered valleys; and frequently possessing, in addition to these weighty charges, the sinecure office of parish schoolmaster.' (*Quart. Rev.* vol. xxix. p. 129.) The Tartar *mulla* and the Persian *MOLLAN* [which see] have evidently a common origin; but their rank and offices are distinct.

Mullein. The common name for the species of *Verbascum*, of which several occur wild in this country.

Mullet (Fr. *molette*). In Heraldry, this term denotes the rowel of a spur. In English blazonry it is depicted of five points: in French of six. It is used as the filial distinction of the third son. [DIFFERENCE.]

MULLET (Lat. *mullus*, Gr. *μύλλος*, although the same word did not denote the same fish). The name of the fishes of the genus *Mugil*, which, in addition to the family characters of the Mugiloids, have the middle of the under jaw produced into an elevated angular point, adapted, when the mouth is closed, to a corresponding groove in the upper jaw; the number of the branchiostegous rays is six. Of this genus there are three British species; viz. the grey mullet (*Mugil Capito*, Cuv.); the thick-lipped mullet (*Mugil Chilo*, Cuv.); and the short mullet (*Mugil curtus*, Yarrell); of these the first species is the least rare. The red mullets (*Mullus Surmuletus*, Cuv.; and *Mullus barbatus*, Linn.) belong to a different family of fishes: the former of these species were the fish so greatly esteemed by the ancient Romans, and for which extravagant prices were given when it had attained an unusually large size.

Mullicite. A native phosphate of iron (Vivianite) found at Mullica Hill, New Jersey.

Mullion. In Architecture, the upright post or bar dividing two lights of a window.

Multarticulate (Lat. *multus*, *many*; *articulus*, *a joint*). In Zoology, a term applied to the antennae of insects, and to the legs of crustaceans and cirripeds, when they are composed of a great number of joints; also to bivalve shells which have numerous teeth in the hinge.

Multicarinate (Lat. *multus*; *carina*, *a keel*). In Conchology, a term applied to a shell which is traversed by many keel-like ridges; as the *Fusus multicarinatus*, *Terebratula multicarinata*.

Multidentate (Lat. *multus*; *dens*, *a tooth*). In Zoology, when a part is armed with many teeth or tooth-like processes. A family of

MULTILOCULAR

Nereids is hence termed *Multidentata* by De Blainville, on account of the structure of their horny jaws.

Multilocular (Lat. *multus*; *loculus*, a case or coffer). In Botany, a term applied to capsules or ovaries which have many cells.

MULTILOCULAR. In Conchology, this term is applied to those shells which, like the nautilus, have their cavity divided into many chambers.

Multinomial (Lat. *multus*; *nomen*, name). In Algebra, an expression consisting of more than two terms, which are connected by the signs of addition or subtraction, + or -. Sometimes it is called a *polynomial*; and in modern works, after the French writers, a *polynome*.

Multinomial Theorem. A theorem discovered by De Moivre for forming the numerical coefficients which arise in raising any multinomial to any given power without the trouble of actual involution. The binomial theorem of Newton is a particular case of this; viz. that in which the number of terms is only two.

It may easily be seen that each term in the expansion of $(x_1 + x_2 + \dots + x_n)^m$ will be of the form $C x_1^{a_1} x_2^{a_2} x_3^{a_3} \dots x_n^{a_n}$, where C is a numerical coefficient, and the exponents may have all possible values, zeros included, subject to the condition $a_1 + a_2 + \dots + a_n = m$. There will consequently be

$$\frac{n(n+1) \dots (n+m-1)}{1, 2, 3 \dots \dots \dots m}$$

terms in the expansion, this being the number of combinations, allowing repetitions, of n things taken m at a time. [COMBINATIONS.] The coefficient C will be equal to the number of different permutations of n letters of which a_1 are of one kind, a_2 of another, a_3 of a third, and so on; hence

$$C = \frac{n!}{a_1! a_2! a_3! \dots \dots \dots a_n!}$$

[PERMUTATIONS.] This is also the numerical coefficient which must be prefixed to the term

$$x_1^{a_1} x_2^{a_2} \dots \dots x_n^{a_n},$$

in the quantic or homogeneous function which Prof. Cayley represents by

$$(*)(x_1, x_2, \dots x_n)^m.$$

[QUANTIC.]

Multiple (Lat. *multiplex*). Any quantity which contains another an exact number of times without a remainder is a *multiple* of the latter, and the latter is a *submultiple* or part of the former.

Multiple Integral. The result of successive integrations. Thus the function of x whose n^{th} differential coefficient is a given function X, would be called a multiple integral of the n^{th} order, and denoted by

$$\int \int \dots \int X dx^{\text{or}} \left(\frac{d}{dx} \right)^{-n} X.$$

Again, if u were a function of n independent

MULTIPLE POINT ON A CURVE

variables $x_1, x_2, \dots x_n$ the function U whose n^{th} partial differential coefficient

$$\frac{d^n U}{dx_1 dx_2 \dots dx_n} = u$$

would also be termed a multiple integral, and denoted by

$$\int \int \int \dots \int u dx_1 dx_2 \dots dx_n.$$

In effecting the integration according to x_n , the other variables must, of course, be regarded as constants, and the integral completed, accordingly, by the addition of an arbitrary function of these variables, before proceeding to the next integration, and so on. In the case of definite integration these arbitrary functions are determined at each successive step. In applications of the calculus we are concerned principally with definite *double* and *triple integrals*. In geometry, for example, we meet with such integrals in problems on the quadrature of surfaces, and cubature of solids. Thus the double integral

$$\iint F(x, y) dx dy,$$

would represent the quadrature of a surface if $F(x, y)$ denoted the reciprocal of the cosine of the angle between the axis of z and the normal at the point x, y, z . The same integral also represents the volume of the space enclosed between a surface, having $z = F(xy)$ for its equation, the plane of xy , and a certain cylindrical surface with generators parallel to the axis of z .

In evaluating multiple integrals much depends upon a suitable choice of coordinates, and it is frequently necessary to transform the variables before attempting the integration. This is done by means of the following formula: If x and y are each replaced by functions of two new variables u and v , then $dx dy$ must be replaced by $J du dv$, where J is the *Jacobian*

$$\begin{vmatrix} \frac{dx}{du} & \frac{dy}{dv} \\ \frac{dx}{dv} & \frac{dy}{du} \end{vmatrix}$$

A similar theorem holds for triple integrals. After transformation, the new limits, of course, require careful determination.

Multiple Point on a Curve. A point through which the curve passes several times. For instance, if every line drawn through a point m on a curve meet the latter in r points coincident with m , then m will be a *multiple point of the r^{th} order of multiplicity*; thus if, in general, u_k represent a homogeneous function of the k^{th} order in the Cartesian coordinates x, y , the origin will be a multiple point of the r^{th} order on the curve whose equation is

$$u_r + u_{r+1} + \&c. \dots = 0.$$

Of the infinite number of lines drawn through such a multiple point, r , at most, will meet the curve in $r+1$ coincident points; these will be

MULTIPLE

the tangents to their branches of the curve which pass through the multiple point, which latter will be characterised by the number of these tangents which are real or imaginary, distinct or coincident. [DOUBLE, CONJUGATE, AND STATIONARY POINTS.] A curve of the n^{th} order will in general possess no multiple points whatever, and should it do so, in exceptional cases, there will be limits to their number as well as to their order of multiplicity. Thus a curve of the n^{th} order possessing a multiple point of the n^{th} order must necessarily consist of a system of right lines through a point; for if the line joining the multiple point with any other on the curve did not lie wholly in the curve, we should have the anomaly of $n + 1$ intersections of a curve of the n^{th} order by a right line. Similarly a proper curve of the n^{th} order having a multiple point of the order $n - 1$ can possess no other multiple point elsewhere, for the right line joining the two would, in such a case, meet the curve in more than n points. In short, it can easily be shown that to demand that a given point shall be a multiple point of the r^{th} order on any curve is equivalent to the imposition of $\frac{r(r+1)}{2}$ condi-

tions. The existence of multiple points has the effect of diminishing the class of the curve, or, what is the same thing, the degree of its reciprocal, and in estimating this effect a multiple point of the order r may be regarded as equivalent to $\frac{r(r-1)}{2}$ double points. [SINGULARITIES OF A CURVE.]

Methods of finding multiple points are given in most treatises on the Differential Calculus. They can, however, be frequently detected at once from the form of the equation of the curve. (Salmon's *Higher Plane Curves*.)

A multiple point on a surface has a similar definition; every right line through it there meets the surface in several coincident points, the number of which determines the order of multiplicity. Such points are sometimes called *conical points*. [CONICAL POINT; DOUBLE POINT, &c.]

Multiple Tangent of a Curve. A line which touches that curve several times. Thus if of the several tangents which can be drawn to the curve from any point of a line, r always coincide with the line itself, the latter will be a multiple tangent of the r^{th} order of multiplicity. Of the r points of contact of such a tangent some may be imaginary or coincident, and the nature of the multiple tangent will vary accordingly. To a multiple tangent on a curve corresponds, of course, a multiple point on its reciprocal, so that the theories of both are intimately connected. [MULTIPLE POINT; DOUBLE TANGENT, &c.]

Multiple Tangent Line of a Surface. A line which touches the latter several times. [DOUBLE AND TRIPLE TANGENT LINES.]

Multiple Tangent Plane of a Surface. A plane which touches the surface in more

MUMMY

than one point; the number of points of contact determines the order of multiplicity. [DOUBLE AND TRIPLE TANGENT PLANES.]

Multiplicand. In Multiplication, the number or quantity that is to be repeated the number of times denoted by the multiplier.

Multiplication. In Arithmetic, an abbreviated method of adding together several equal numbers. The result is termed the *product*, any one of the equal numbers is called the *multiplicand*, and the number which indicates how many of the equal numbers are to be added is called the *multiplier*.

Multispiral (Lat. *multus*; spira, Gr. *σπῆλαι*, a spiral turn). In Conchology, this term is applied to those opercula of univalve shells which exhibit very numerous and narrow spiral coils round a submedian centre.

Multistriate (Lat. *multus*; stria, a streak). In Zoology, when an animal or part is marked with many streaks.

Multivalve (Lat. *multus*; valva, a valve). In Conchology, when a shell consists of several calcareous pieces; as that of the chiton or barnacle.

Multoca. The name given to the code of laws by which the Turkish empire is governed; consisting of the precepts contained in the Koran, the oral injunctions of Mohammed, and the decisions of the early caliphs and doctors. It relates to every subject of life, and comprises various matters appertaining to government, the sultan being the sole judge of its application to particular cases. [SULTAN; VIKA.] (*Edinburgh Review*, vol. x. p. 259.)

Multungulate (Lat. *multus*; ungula, a hoof). In Mammalogy, when a quadruped has the hoof divided into more than two parts corresponding with three or more digits; as the elephant, rhinoceros, &c. Ray so denominated a family of hooved quadrupeds corresponding with the *Polychida* of Aristotle.

Multure. In Scotch Law, the toll or emolument given to the proprietor of a mill for grinding corn.

Mum (Ger. *mumme*). A malt liquor made chiefly at Brunswick of the malt of wheat, with the addition of a little oat and bran meal.

Mumia Mineralis. A bituminous substance resembling brown asphalt.

Mummiform. In Entomology, the nymphs of certain Lepidoptera are so called which resemble an Egyptian mummy.

Mummy (Arab. *mumia*, from *mum*, wax). The name given to dead bodies preserved in a dry state from putrefaction. Mummies have been divided into two classes—natural and artificial; the former arising from peculiar conditions of soil and atmosphere, which permit of the drying of the animal tissues; the latter embracing the various means that have been employed to preserve dead bodies from corruption. Of the former or natural class of mummies, instances are to be found in the vaults of several Continental churches, particularly at Strasburg, Toulouse, and Bordeaux.

The art of embalming owes its origin to the

MUMMY

veneration with which the ancient Egyptians regarded the corpses of their relatives and of the animals which their religion held sacred; of these upwards of fifty different species have been found embalmed. The art was practised also by the ancient Jews, Greeks, and Romans, though it never attained such perfection among them as among the people from whom it was borrowed. It was also adopted as a national custom by the Guanches, the ancient inhabitants of the Canary Islands; a full account of which is to be found in the *Essai sur les Isles Fortunées*, by M. Bory de St. Vincent.

The account which Herodotus has left us of the Egyptian process of embalming has been simply confirmed in all essential particulars, not only by subsequent ancient writers, but in still more recent times (see the *Memoir* of M. de Rouyer). According to this account, there were three processes employed by the professional embalmers. In the most costly method, the brain was extracted through the nostrils by a hooked iron instrument, as well as by the infusion of drugs. The viscera were then removed through an incision in the side; and the belly, having been filled with myrrh, cassia, and odoriferous herbs, was sewn up. The corpse, rubbed with natron, was then buried for seventy days, at the end of which time it was smeared over with gum, and restored to those who brought it. The second method consisted in filling the intestines with cedar oil, without any extraction of the viscera: the oil, having been kept in the body for some time, brought away with it, when drawn off, all the bowels and viscera in a fluid state, while the natron destroyed the flesh, leaving only the skin and the bones. In the third mode of embalming, for the poor, a mixture of salt and water was injected into the body, which was then wrapped up in natron.

It was long a matter of uncertainty what became of the intestines after they had been removed from the body of those embalmed according to the first process. Porphyry and Plutarch have both asserted that they were thrown into the Nile; but modern discoveries in the tombs leave no doubt of the fact that they were embalmed separately, and deposited in four vases in the coffin. (Sir G. Wilkinson's *Manners and Customs of the Ancient Egyptians*, vol. ii. p. 467, second series.)

Diodorus mentions three different classes of persons who assisted in preparing the body for the funeral: the scribe, who regulated the incision in the side; the *paraschistes*, or cutter; and the embalmers. To these may be added the undertakers, who wrapped the body in bandages, and who had workmen in their employment to make the cases in which it was deposited. Many different trades and branches of art were constantly called upon to supply the undertakers with things required for funeral purposes: as the painters of mummy cases; those who made images of stone, porcelain, wood, and other materials; the manufacturers of alabaster, earthenware, and bronze

MUNICIPALITY

vases; those who worked in ivory; the leather cutters, and many others.

It appears that the early Christians embalmed their dead, and, according to St. Augustine, mummies were made in his time, at the end of the fifth century. But it is probable that at the period of the Roman invasion of Egypt the custom was on the decline; and Sir G. Wilkinson maintains that in all probability it fell gradually into disuse, rather than that it was suddenly abandoned from any accidental cause connected with change of custom, or from religious scruples.

Mumps (Dutch mumps). This term is generally applied to inflammation of the parotid glands. It is seldom attended by much fever or constitutional symptoms, but is occasionally translated to other glandular parts. A gentle dose of physic, and the application of a piece of flannel dipped in warm salt water or in solution of acetate of ammonia, is generally all the treatment required. From the way in which this complaint sometimes spreads in families or schools, there is some reason to believe it to be contagious. It sometimes appears epidemically.

Mundic. A Cornish mining term for Iron Pyrites.

Mundificant (Lat. *mundare*, to cleanse). A term applied in old Pharmacy to certain healing and cleansing ointments and plasters.

Mungo. A term applied to woollen cloth manufactured from old wool obtained from the rags of hard fabrics, the rags being torn into fibre by cylindrical machines armed with teeth. This cloth gives substance and warmth, and is capable of a fine finish, but from the shortness of the fibre is weak and tender. It is chiefly used for paddings, linings, office coats, druggets and blankets. Broadcloth is sometimes made with a large admixture of this cheap and inferior material. [SHODDY.]

Municipality. The word *municipes*, in the language of early Roman jurisprudence, signified a person capable of holding an office or dignity (from *munus*, an office, and *capio*, I take). It was appropriated in its more particular meaning to those who, by the constitution of Rome, were admissible to certain privileges and honours, but not to the right of suffrage or magistracy, in consequence of not being full citizens. These were the strangers who in various ways became incorporated with the Roman people without acquiring the right of citizenship. The juriconsult Paulus (as cited by Festus) notices three sorts of municipes: 1. Free strangers settled in Rome; 2. Citizens of commonwealths which became absorbed in that of Rome by conquest or submission (*quarum civitas universa in civitatem Romanam venit*): such were Aricia, Cære, Anagnia; 3. Citizens of allied commonwealths, who retained their citizenship at home while at the same time they became municipes of Rome: such were Tibur, Pisa, Arpinum. It is plain that this last is the sense in which the citizen of one state was

MUNIMENTS

said to be municipes of another. Towns of the last two kinds (if the passage of Paulus is correctly understood) were probably comprehended by the Romans under the title of *municipia*; i. e. towns which possessed their own rights, and the burgesses of which were also municipes of Rome. Such burgesses often acquired full Roman citizenship and even dignity, but seem to have been always (in the republican times) regarded as of recent and comparatively ignoble franchise: as in the passage of Juvenal respecting Cicero (*ignobilis et modo Romæ municipalis eques*); i. e. one coming from the municipium of Arpinum. By later writers, *municipia* are sometimes confounded with colonies. The word *municipal* and its derivatives have passed into modern usage in two different senses: 1. The local government of a small district, especially of a town, and particularly if elective, is termed a municipality: such are municipal corporations in England; 2. Every Latin municipium had its own customary law (*jus municipale*). Hence with later jurists municipal law came to signify the law of particular towns, districts, and provinces. In this latter sense the customs of the French cities and provinces were called *municipal laws*. Among modern publicists the word has received a still greater extension; the positive law of a country (in opposition both to natural or moral law and to the law of nations) being often called its municipal law. The same term is also sometimes used rather vaguely in contradistinction to the constitutional or political law of a state; as where crimes are divided into offences against the state and municipal offences.

Muniments (Lat. munimentum, from *munio*, I fortify, as serving to defend the title). A common name, in Legal phraseology, for deeds, charters, and other instruments evidencing the title to landed property: great landowners have generally a *muniment room* in which these are kept.

Munjeet. Indian madder, the produce of *Rubia cordifolia*.

Muntjaks. In Zoology, a subgenus, *Cervulus*, of stags, distinguished by having the horns supported on bony pinnacles; they are found in the Asiatic Archipelago.

Muntz's Metal. An alloy of copper and zinc, used for the sheathing of ships, composed of 60 per cent. of copper and 40 of zinc. It admits of hot rolling.

Murenoids (Lat. murena, a species of eel). The name of a family of Apodal fishes, including the true eels (*Anguilla*) and the eels without pectoral fins (*Murena*). The fishes of the latter genus are more voracious, and have their jaws armed with more formidable teeth than the *Anguilla*. One species (*Murena Helena*) was much esteemed by the ancients, who fattened it in ponds expressly constructed for the purpose.

Mural Circle or Mural Arc or Quadrant. In Astronomy, an instrument, generally of large size, attached to a stone wall or pier of

MURAL CIRCLE

solid masonry, and fixed in the meridian for the purpose of measuring the distances of stars from the pole or the zenith. The first mural quadrant, or rather arc, used at Greenwich, was erected by Flamsteed in 1689, and divided by Abraham Sharp. There are still two quadrants in the Observatory, each about eight feet radius; one of them was erected by Graham in 1725, for the observations of Halley, and was redivided by Bird in 1753; the other was constructed by Bird in 1750, and is the instrument with which Bradley and Maskelyne made their most important observations. Experience having shown that entire circles are susceptible of much more accurate division, and are much less liable to derangement than quadrants, a mural circle was constructed by Troughton, and placed in the Observatory in 1812. Since that time the advantages of this construction have been fully appreciated; and a mural circle is now regarded as the principal fixed instrument in all the great public observatories.

Troughton's mural circle is six feet in diameter. It is formed of brass, and fixed by means of sixteen conical radii, concentric to and at right angles with a conical axis nearly four feet long, seven inches in diameter at the extremity at which the circle is fixed, but only half as much at the other extremity. The axis rests and turns in two collars, one towards each end of the cone, fixed at the front and back of a stone pier about four feet in depth. The degrees are cut into five spaces, on a narrow ring of white metal composed of gold and palladium. The divisions are read by six micrometers, placed at equal distances round the circle, and securely fixed to the stone pier. The telescope is fixed at right angles to an axis which works within the conical axis of the circle. It consequently moves in the plane of the circle, and can be clamped in any position, so that the readings may be made on different parts of the circle. In order that the circle may move easily round its axis, and that the lower side of the front socket may be relieved from the load of the instrument, two large friction wheels are suspended in front of the pier from the arms of two levers, which, by means of counterpoises, may be made to support the whole or any part of the weight. The details of construction, however, admit of being varied in many different ways.

The use of the mural circle is to measure angular distances in the meridian. The axis must therefore be placed exactly horizontal, and the plane of the circle vertical and in the meridian, and the line of sight at right angles to the axis and parallel to the plane of the circle. Small errors, however, in the adjustments scarcely affect the results. The advantages of the mural above all other astronomical circles consist in the permanence of the microscopes, and the facilities for observing stars by reflection. (For a detailed description of this instrument, see Pearson's *Practical Astronomy*; also Dr. Robinson's 'Description of the Mural Circle of the Armagh Observatory,' in vol. ix

MURCHISONITE

of the *Memoirs of the Royal Astronomical Society*.)

Murchisonite. A variety of Felspar, of a golden or red and yellow colour, found in the Isle of Arran, and in rolled pebbles, at Dawlish and at Heavitree near Exeter. It is named after the discoverer, Sir Roderick I. Murchison.

Murder. In English Law, the killing any person under the king's peace, with malice prepense or aforethought, either express or implied by law. The word is of the same origin with the German *mord*, French *meurtre*; in law Latin, *murdrare*, which word was, before 4 Geo. II., when legal proceedings were in Latin, an essential term of art, so that *murderavit* instead of *murdravit* vitiated an indictment. (2 Hale 187.) The malice prepense is the chief characteristic which distinguishes murder from other species of homicide; and it is the great office of the jury to determine whether or not such malice has been shown: either express, as evinced by outward circumstances; or *implied*, as where one deliberately kills another without provocation the law implies malice. Malice is also *implied* where persons having authority to arrest or imprison, using the proper means for that purpose, are resisted in so doing, and killed, which offence is murder. Killing in the prosecution of an unlawful act, when the act is done deliberately and with intention of mischief either indiscriminately or to particular individuals, is likewise murder, whether or not there was a premeditated design of killing the individual slain. So where particular malice against an individual is wreaked, by mistake against another. Whenever, also, death ensues on an unlawful act done in prosecution of a *felonious* intention, it is murder; as where a man is killed by a shot discharged at an animal with intent to kill and steal it; or where the intent is only to do some great bodily harm, and death ensues. When several assemble to commit a breach of the peace forcefully, and happen to kill a man in the prosecution of such intention, they are all guilty of murder. In some cases, also, murder may be the consequence of a lawful act criminally or improperly performed, as by duress in a gaol.

The execution in cases of murder, by 25 Geo. II. c. 37, was to take place the next day but one after sentence, unless stayed by the discretion of the judge; with an exception for Sunday, by 9 Geo. IV. c. 31: and it was usual to sentence on Friday, in order that the Sunday might intervene before execution. But, in 1836, by 6 & 7 Wm. IV. c. 30 the time before execution was made the same as in other capital offences. (See now 24 & 25 Vict. c. 100.)

By the French code pénal of 1810, the several kinds of homicide are accurately defined; and the crimes of assassinat, parricide, infanticide, and empoisonnement are capital. But the power given to the jury by the code of 1808, of pronouncing *under what circumstances* a criminal act has been committed, materially

MURIATIC ACID

modifies the severity of the law. If extenuating circumstances are found by the jury, the punishment is diminished.

Murex (Lat. *a shell-fish*). A name applied by Linnæus to a genus of *Vermes Testaceæ* having a univalve spiral shell, with an oval aperture ending in an entire, straight, or slightly ascending canal. The Molluscs thus characterised form a family (*Muricula* or rock-shells) in the order of Prosobranchiate Gastropods of the system of Woodward, and include the following genera: *Murex*, *Pisania*, *Ranella*, *Triton*, *Fasciolaria*, *Turbinella*, *Cancellaria*, *Trichotropis*, *Pyrula*, &c. The celebrated Tyrian purple dye was obtained from two little shell-fish, the *Buccinum* and *Murex*, the former being found on rocks near the shore, and the latter in deeper water on the Phœnician coast.

Murexan. The *purpuric acid* of Dr. Prout. Its formula is $C_6H_4O_5N_2$.

Murexide (Lat. *Murex*). The *purpurate of ammonia* of Dr. Prout. It is best obtained by adding four grains of alloxah, and seven of alloxantine, dissolved in half an ounce of boiling water, to one-sixth of an ounce of a saturated solution of carbonate of ammonia. The liquor acquires a magnificent purple colour, and deposits small crystals of murexide, which are green, and iridescent by reflected light, but deep red by transmitted light: they form a beautiful microscopic object. The chemical formula of murexide is $C_{12}H_6O_8N_5$. Murexide has been successfully used as a dyeing material. [Uric Acid.]

Muriacite. A mineralogical synonym for Anhydrite (anhydrous sulphate of lime) when it contains common salt, with which it is frequently associated.

Muriatic Acid or Hydrochloric Acid.

This acid was discovered by Glauber, and called by him *spirit of salt*. In its pure or gaseous form it was first obtained by Priestley in 1774; its composition was shown by Davy in 1809, who proved it to be a compound of hydrogen and chlorine. It is procured in the gaseous state, by acting upon common salt (chloride of sodium) by sulphuric acid; the water of the acid is decomposed, and its hydrogen combines with the chlorine of the salt to form hydrochloric acid; whilst the oxygen is transferred to the sodium, which is thus converted into soda, and this unites to the sulphuric acid to form sulphate of soda. 59 parts of common salt, and 49 parts of concentrated sulphuric acid, afford, by their mutual action, 37 parts of muriatic acid, and 71 of sulphate of soda. This acid may also be formed by passing an electric spark through a mixture of equal volumes of chlorine and hydrogen; or by exposing such mixture to the sun's rays, or inflaming them by a taper, they burn with explosion, and form a volume of the acid equal to the united volumes of the gases. As the specific gravity of hydrogen is to that of chlorine as 1 to 36, the specific gravity of the resulting hydrochloric acid gas compared

MURICATE

with hydrogen will be 18.5, and 100 cubic inches of it will weigh 39.5 grains. Hydrochloric gas is rendered liquid under a pressure of 40 atmospheres at the temperature of 50°; it extinguishes flame, and is intensely sour, powerfully reddening vegetable blues. Water absorbs it with much violence, taking up about 480 times its volume. This is the state in which this acid is generally used. Its specific gravity is about 1.19, and it is commonly obtained by distilling a mixture of equal weights of salt, sulphuric acid, and water. When hydrochloric acid acts upon metallic oxides, a mutual decomposition of the oxide and acid generally ensues; the oxygen of the oxide unites to the hydrogen of the acid to form water, and the metal to the chlorine to form a metallic chloride. Thus it is that soda and hydrochloric acid form chloride of sodium. The most effective test of the presence of hydrochloric acid is nitrate of silver, which forms an insoluble chloride of silver in solutions containing it.

Muricate (Lat. *muricatus*, pointed like the *muræx*). In Zoology, where a surface is armed with short, but not close-set cones, having a sharp apex.

Muridæ (Lat. *mus*, a mouse). The family of Rodents, of which the genus *Mus* is the type: by some naturalists it is restricted to the genera *Mus*, *Hesperomys*, *Dendromys*, *Smithus*, *Perognathus*, *Cricetus*, *Gerbillus*, *Hydromys*, *Haplotis*, and *Psodromys*; by other naturalists it is extended to include the *Jerboideæ*, *Myoidæ*, and *Castoridæ*.

Murines (Lat. *mus*). The name of a tribe of Rodent quadrupeds, of which the genus *Mus* is the type: it includes the families *Muridæ*, *Arvicolidæ*, and *Scuridæ*, and is the most widely distributed of all the Rodent tribes.

Muromontite. A variety of Allanite found in black grains at Mauersberg and Boden in the Saxon Erzgebirge.

Murrain (Fr.). The popular term applied to various malignant diseases to which cattle are subject, and which have at various times made terrible havoc among them.

Thus a disease raged extensively on the Continent from 1710 to 1746. (Lancisi, *Disputatio Historica de Bovilla Peste*.) During that period many written descriptions were produced of this pest, among which the work of Sauvages, the celebrated professor of medicine at Montpellier, stands pre-eminent. The disease produced in 1767 a great mortality among the cattle of this country; an account of this malady was published in the excellent work by Dr. Laidlaw, a physician of London.

The murrain, as commonly met with in England, may be characterized as an extremely malignant inflammatory *ædema*, attacking, and indeed confining itself for the most part to one of the hind quarters of the animal. It is most common in the seasons of spring and autumn, and affects principally young cattle. The most prominent features are tumefaction and a discolouring of the side affected, with consequent lameness and inability to move; emphy-

MURRAIN

sema of different parts of the body, but particularly over the region of the spine; and all the symptoms of putrid fever present in diseases of a typhoid character. It speedily runs on to gangrene, and few animals survive an attack of this kind more than ten or a dozen hours.

Although this English murrain is somewhat modified in its virulence by season, locality, and the condition of the sufferer, it is nevertheless generally looked upon as incurable. It affects chiefly young animals in good condition at changes of food in spring and autumn.

Another murrain is the so-called pleuropneumonia, an inflammation of the lungs and of the membrane surrounding them, which first became contagious in this country in 1840, and has since, at intervals, destroyed great numbers of cattle in the dairy districts. Then there is the so-called foot and mouth disease, another epizootic which has done mischief enough (without being really fatal) to deserve the name of murrain. Lastly, we have had since midsummer (1865) the Siberian rinderpest, or true cattle murrain, often destroying whole herds. It is apparently a typhoid fever, producing characteristic eruptive blotches and abscesses in the intestinal canal, and resulting in death after a few days, during which there is a mucous discharge from the nose and eyes, fetor of breath, ulceration of palate, and profuse diarrhoea.

Initi attempts to deal with this terrible disease, the veterinary science of the day has shown itself almost powerless. The variety of remedies applied, and the singular conflict of opinions on the efficacy of those remedies, prove at least the absence of all systematic attempts to record and classify the symptoms of the malady as from time to time it has made its appearance. From the vivid description given by Virgil in the third *Georgic*, it would seem that the epidemic which ravaged Northern Italy in his day much resembled the present cattle plague; and for at least seventeen years during the last century the effects of the same or a like disease were felt in this country. Yet it has been not unjustly said that 'there seems to be hardly a thread of experience to be disentangled from the story of those ravages which might form a clue to our present difficulty.' The one authoritative remedy at present is the slaughter of the herd in which a single tainted animal is found—course which savours strongly of panic, and protects, or seeks to protect, the community at the expense or even by the ruin of the owners of diseased herds. Such a system not only casts a grave reflection on the veterinary science of the time, but tends to excite a spirit of panic, which may cause serious mischief during future epidemics among human beings. It can scarcely be considered safe or prudent to adopt a course which resembles those savage instincts of the lower creatures, according to which a sick bird is pecked to death, and a maimed wolf torn to pieces by the

MURRHINE

pack; and it may be remarked that all competent medical writers on the subject agree in denying that the disease is incurable, and in condemning the method of indiscriminate massacre.

It is possible that observations of the symptoms of the present disease may lay the foundation for a real veterinary science; but, for the present, the prevention of the malady is more important than the question of medical treatment, and, like that of all other infectious diseases, consists in carefully secluding the herd from contact with diseased animals, and in allowing free access of air to all buildings, stalls, &c., with daily fumigation of them by proper disinfectants. Care should be taken to examine three or four times a day the cattle on every farm, so as to remove the healthy animals as soon as possible from those that are affected. In other words, ventilation and cleanliness are found to be as indispensable for the health of cattle as for that of men.

Murrhine (Lat. *murrhina vasa*, from Gr. *μυρρίη*). The material of the murrhine vases, often mentioned by writers of the Roman empire, has been a subject of much dispute among modern antiquaries. The vases came from the East, and, according to Pliny, were made of some precious stone found chiefly in Parthia; but some have conjectured that this was an erroneous opinion prevalent among the Romans, and that they were in reality of porcelain, of which the manufacture was unknown to the Western nations. (Plin. *Hist. Nat.* l. 37; see also a memoir in the 43rd vol. of the *Mém. de l'Acad. des Ins.*; and Maurice's *Indian Antiquities*, vol. vii.)

Murru or Sanguine. In Heraldry, a dark red; one of the colours or tinctures employed in blazonry, expressed in engraving by opposite diagonal lines crossing each other. It is reckoned a dishonourable colour, and is rarely to be met with in English coats of arms.

Murzas. The name given to the hereditary nobility of the Tartars, or, more strictly perhaps, to the second class of their nobility; the first or principal class being designated *beys*. This titular appellation is also sometimes conferred on the descendants of public officers; but the latter are looked upon as upstarts by the older nobility, and regarded as an inferior race. The Murzas have from the earliest ages been distinguished for their bold and refractory character; and the privileges which they formerly possessed supplied them with the means of giving effect to their turbulent dispositions. Since the conquest of Tartary, they have sunk into comparative insignificance; though many of them retain a large share of their former property, and have considerable influence among their own countrymen. (*Quart. Rev.* vol. xxix. p. 128.) The Tartar *murza* is evidently of the same origin with the Persian *mīrza*; with which, however, it must not be confounded. [**MIRZA.**]

MUSCHELKALK

Mus (Lat.). A genus of Rodent Mammalia, comprising many species, which are found in nearly every part of the world. The most familiar examples are the Norway or Common Rat (*Mus decumanus*), the Black Rat (*Mus Rattus*), the Mouse (*M. musculus*), the Long-tailed Field-mouse (*M. agrestis*), the Harvest Mouse (*M. messorius*), and the Wood-mouse (*M. sylvaticus*). These species are found in great numbers, and will devour food of almost every sort. The *M. giganteus* of Hardwicke, found in Southern India, weighs more than two and a half pounds, and measures more than two feet in length. This species happily has not, like the Brown Rat, been introduced into Europe. The latter species has completely extirpated its predecessor, the black rat, in many of the great towns of England. The latter species has now become exceedingly rare. The species of the genus *Mus* are distinguished by the great rapidity with which they increase their number.

Musa. [**BANANA.**]

Musaceæ (Musa, one of the genera). A small but important natural order of Endogenous plants belonging to the Amomali alliance, and related to the orders yielding ginger, arrow-root, &c.; but differing in having several stamens instead of one only. The Plantain (*Musa sapientum*), the most valuable product of the vegetable kingdom in hot countries, from the abundance of nutritious food yielded by its fruit, and from the application of its leaves in thatching, and of thread obtained from its petioles in the manufacture of the finest muslins, is the representative of the order. Another species is the *Musa paradisiaca*, or Banana; and the singular plants called *Strelitzias*, with their orange and blue flowers, are also members of the order of *Musaceæ*.

Musca (Lat. a fly). A Linnean genus of Dipterous insects, now expanded into a family (*Muscidae*) of the fifth tribe (*Athericera*) of the order *Diptera* in Latreille's system. It is distinguished by a proboscis always very apparent, membranous, and bilabiate, generally bearing two palpi, and capable of being entirely withdrawn into the oral cavity; and a sucker of two pieces. The antennæ always terminate in a plate with lateral setæ. The *Muscidae* are divided into the sub-families *Creophilæ*, which includes the meat-fly (*Musca vomitoria*) and the common house-fly (*Musca domestica*); the *Anthomyzæ*, the *Hydromyzæ*, the *Scatomyzæ*, the *Dolichocera*, the *Leptopoditæ*, the *Capromyzæ*, the *Gymnomyzæ*, and the *Hypocera*.

Muscadine or Muscatel. A rich sweet wine made of Muscadine grapes in the South of France. These grapes are also dried on the vine, for fine table raisins.

Muschelkalk. The name given to the shelly limestone occupying the middle of the Triassic series of rocks on the continent of Europe. It is absent in England, and for this reason the upper and lower divisions of the new red sandstone run together, and are almost inseparable. The muschelkalk contains a good number of

MUSCI

characteristic fossils. It is generally compact, and of a pale ashy grey colour, but is sometimes bituminous, emitting a fetid odour when struck by the hammer.

Though not found in England, it is remarkably persistent in most parts of Western Europe, and almost always in its typical form. Among the fossils are some reptilian remains; and a peculiar Ammonite (*Ceratile*), intermediate between those of the carboniferous limestone and the secondary rocks, is almost if not absolutely characteristic of it.

Musci. [Mosses.]

Muscicapa (Lat. *musca*, a fly; *capio*, I take). A genus of Dendrostruthal Passerine birds, characterised by a depressed beak, furnished with hairs at its base, and with the point, more or less hooked and emarginate. The genus is now split into various subgenera; as *Tyrannus*, *Gymnocephalus*, *Muscipeta*, and *Muscicapa* proper, &c., included in the family name of *Muscipidæ*. Their general habits are cruel and predatory, like those of the shrikes; and, according to their size and strength, they live on small birds or insects. The smallest and weakest of the *Muscipidæ* gradually approach the form of the wagtails.

Muscidae. The family of Dipterous insects of which the fly (*Musca*) is the type.

Musciformes (Lat. *musca*, a fly; *forma*, form). The name of a tribe of *Tipulidæ*, or crane-flies, comprehending those which have a stout body and short legs, resembling the common flies.

Muscle (Lat. *musculus*, Gr. *μῦς*). Fleishy fibres susceptible of contractions and relaxations. Some of the muscles are obedient to the will, and therefore called *voluntary*; others, such as the heart, are independent of the will, or *involuntary*; and others, as the diaphragm and muscles of respiration, generally have a *mixed* action, being to a certain extent only dependent upon the will. Muscles are aggregates of minute muscular fibres, which appear to be composed of small globules; but we are, in fact, ignorant of the ultimate structure of the muscles, and of the causes on which their wonderful powers depend. They are enveloped in and penetrated by cellular membrane, and abundantly supplied by nerves, blood-vessels, and lymphatics.

When muscular flesh or fibre is carefully dried, it loses about 75 per cent. of water, so that a pound of what is usually called raw lean meat includes only about four ounces of what may properly be termed nutritive matter. When lean beef or other flesh is very finely minced, and digested in small but repeated portions of cold water, and well expressed, the principal soluble matters of the muscular tissue are squeezed out of it, and may be thus obtained in concentrated solution, the fibrine, fat, albuminous tissues, and some other insoluble bodies remaining in the residue. The juice thus obtained has an acid reaction; it contains phosphoric, inosic, lactic, butyric, and perhaps some other acids, tinged by the colouring prin-

MUSES

ciple of the blood; albumen and the salts of the blood are also found in it, together with kreatine and inosine; the latter, which has also been called *muscle-sugar* ($=C_{12}H_{12}O_{10} + 4HO$), being a peculiar crystallisable sweet substance, not susceptible of vinous fermentation, and said to be chiefly confined to the involuntary muscles, more especially to the heart. (It is also said to be occasionally present in the urine, and to be identical with *phasedomannite* or the sugar of the kidney-bean, *Phaseolus vulgaris*.) When the juice of flesh, obtained as just stated, is heated, it becomes turbid, and deposits albumen tinged by colouring matter, the coagulum amounting to about 3 per cent. of the fresh muscle. Fibrine, gelatine, albumen, fat, and other constituents of the muscle forming its fibre, nerves, vessels, &c., are the principal substances which remain after the exhaustion by cold water, and are of course highly important in reference to their value as elements of nutrition.

All the muscles are under the immediate influence of the brain and nerves; and consequently when this influence is abstracted, as by the division of the nervous trunks by which they are supplied, the powers and functions of the muscles, whether voluntary or involuntary, are in the first instance disturbed, and afterwards cease altogether. Electricity is capable to a certain extent of recalling the action of the muscles, provided it be applied before rigidity ensues; hence the supposed identity of that power of matter and certain properties of the nerves. The arrangement of the fibres of muscles is infinitely various, and adapted to the particular purposes which each has to fulfil. In the voluntary muscles the fibres are generally parallel, or nearly so; but in the involuntary muscles they are more or less interwoven and interlaced. When muscles contract, they become shorter, harder, and thicker, and their bundles of fibres are thrown into undulated lines, with a tremulous or vibratory motion, most rapid where the contraction is most powerful, and producing a distinct sound, which may be most easily heard when the tip of the finger is put into the ear; it occasions a noise like that of carriages rumbling over a distant pavement. (Wollaston, *Philosophical Transactions*, 1809.) The number of these vibrations amounts to between twenty or thirty in a second: these muscular sounds are importantly concerned in the diagnosis of certain diseases through the medium of the stethoscope.

Muscle Band. In coal-mines, the black shale containing embedded muscle shells.

Muscovado. The name given to unrefined or moist sugar.

Muscovy Glass. A synonym of *Mica*, from its having been formerly used in Russia as a substitute for window-glass.

Muses (Gr. *Μοῦσαι*, Lat. *Musæ*). In Mythology, the goddesses of music, poetry, art, and science. The worship of the nine Muses was a later development. Pausanias states

MUSETTE

that originally three were worshipped on Helicon, *Meleté*, *Mneme*, and *Aoidé*, or Reflection, Memory, and Song (ix. 291). Hesiod (*Theog.* 775 &c.) gives the names of nine, and calls them daughters of Zeus and Mnemosyne (or Memory), holding them to be the sources of eloquence, music, and wealth. [PIERIDES.]

Musette. A name sometimes given by the continental nations to the bagpipe. The itinerant performers on the musette, who were formerly very numerous in many European countries, were called *musars*.

Museum (Gr. *μουσεῖον*, from *μῦσα*, a muse). A collection of curious objects in nature and art; but, in most instances, the former. The name denotes a temple or place sacred to the Muses; and is said to have been first given by Ptolemy Philadelphus to that part of the royal palace at Alexandria in which he placed the famous library. In England, the museum at Oxford is the most ancient institution bearing the name. It was founded in 1679, and enriched, in the first instance, chiefly by the contributions of Elias Ashmole; but want of room and of funds has prevented it from affording an adequate exhibition of the various classes of objects for which it was originally destined, and which modern discoveries have so greatly augmented. The foundation of the British Museum, in London, was laid by Sir Richard Cotton's presentation of his collection of manuscripts. Since that period the library has been increased by the addition of the Harleian, Lansdowne, Egerton, and several other collections of MSS.; by extensive purchases out of funds afforded by government; by the deposit of copies of newly published works, according to the legal right conferred on this institution; and by the donations of George III. and George IV., the latter of whom presented to it his father's library. In sculpture, the British Museum possesses among other things the collection of marbles brought by Lord Elgin from Greece, that called the Townley marbles, an assemblage of Egyptian, and the Layard or Nineveh works of art, together with recent acquisitions from Lycia and other parts of Asia Minor. It contains also the Hamilton vases, the famous Berberini or Portland vase, and the collection of Etruscan art formed by Sir W. Temple. In several departments of natural history, especially in mineralogy, it is extremely rich. It was founded by Sir Hans Sloane in 1733, and filled the mansion known by the name of Montague House, until the present buildings were erected. The most celebrated museum in Italy is the Vatican, at Rome; next to it that of Florence, and the Museo Borbonico, at Naples. In France, as well as in Italy, galleries of pictures are considered as within the meaning of the general term *musée*, and the museum of the Louvre is chiefly remarkable for its contents of this description.

Mushroom (Fr. *mousseron*). The *Agaricus campestris*, or eatable agaric—a species common in pastures, and well known for its culinary

MUSIC

excellence. The term is sometimes applied indiscriminately to all firm fleshy species of the genus *Agaricus*, whether eatable or not.

There is no doubt that *Agaricus campestris* is preferable to any of the allied species, though it must not be regarded as the only one that is wholesome. Indeed, it is rejected from many Italian markets, where species of more suspicious character are allowed to pass muster. A large variety of the mushroom called the Ox Mushroom measures sometimes fifteen inches across, with a proportionately stout stem. The pileus is rough with scales; the gills are quite free, leaving a groove round the top of the stem; the smell is powerful, but agreeable. It grows in enormous rings many yards in diameter, and is wholesome, and of fine flavour.

It is impossible to give any general rule for avoiding poisonous mushrooms; but no one should eat Fungi which have a revolting smell, or leave a hot sensation in the mouth and throat. They should moreover always be eaten in moderation, and well masticated. In case of accident, an emetic should be taken immediately, and medical advice called in; for the symptoms of poisoning from fungi are too grave to be trifled with by domestic medicine.

Mushtāhids. In Persia, high priests who represent the vicar of the Imam; they are usually three or four in number, and exercise enormous influence in the administration of the written law.

Music (Gr. *μουσική*, sc. *τέχνη*). Literally, any art over which the Muses presided. The primitive Athenian education consisted of two branches, *music* for the mind, *gymnastics* for the body, but the former term had a much wider signification than that which it now bears. It comprehended not merely the use of the lyre or the taking part in a chorus, but also elocution; and as knowledge advanced, the term was so extended as to include all the learning and accomplishments of the age. In the more modern and restricted sense, music is the art of combining sounds in a manner agreeable to the ear.

Hebrew Music.—Notwithstanding the labours of the early fathers of the church, and of many other learned men, there are few materials, even in the Old Testament Scriptures, for a satisfactory account of the music of the Jewish people, whose restricted intercourse with other nations prevents our receiving any illustration of it from contemporary writers. From several passages in these Scriptures music appears to have been united with prophecy. Samuel (1 Sam. x. 5) says to Saul, "Thou shalt meet a company of prophets coming down from the high place, with a psalmtery, and a tabret, and a pipe, and a harp before them." These prophets were doubtless poets or psalmists, improvisatori of verses which they sang to the accompaniment of an instrument; and many of the fathers have supposed that the Jews had a college or school of prophets, which was also a school of music, for they almost universally accompanied themselves, or were

MUSIC

accompanied by others, with musical instruments. During the reign of David music was much esteemed. He appointed a great corps of musicians for the celebration of the religious ceremonies; and his patronage necessarily extended its influence. But for some time before the destruction of the Temple and the first Babylonish captivity, music and the sacred rites had met with interruption, both on account of war and by their intercourse with foreign nations. The Babylonish captivity was a mortal blow to the endeavours they had made to recover their music. The subsequent inroads of Egyptians, Persians, and Romans successively left the unfortunate Jews no leisure to cultivate the arts; and it appears probable that their music, which scarcely deserved the name till the reign of David, depended for effect, even at its best epoch, more upon the number of performers than upon any refined knowledge of the art.

Among the modern Jews, instrumental as well as vocal music was excluded from the synagogue from the time of the destruction of Jerusalem. The singing allowed at the present day is a modern innovation: for, according to a passage of their prophets, the Jews consider it contrary to their law, or at least improper, to sing or rejoice until the coming of the Messiah. The German Jews alone at the present day have a regular musical establishment in their synagogues. They sing in parts, and have preserved traditional melodies, which are considered very ancient. At Prague an organ is used to accompany the singing.

Egyptian Music.—The opinion of the ancients was pretty general that Pythagoras was indebted to the lessons of the Egyptian priests for nearly all the science he possessed, and especially that of music. Though Diodorus Siculus assures us that the Egyptians were not allowed to cultivate music, and that they considered it useless and even injurious to society, and the cause of effeminacy; yet Plato, who had visited Egypt, observes, in one of his Dialogues, that none but excellent music was allowed where the youth were assembled. Strabo tells us that the youth were instructed at the earliest age in music, that the songs were fixed by law, and that the sort of music used was established by the government exclusive of every other sort. The Greeks even attributed the invention of some of their musical instruments to the Egyptians; such as the triangular lyre, the single flute, the drum, and the sistrum (Gr. *σίστρον*, a rattle).

Like all other professions in Egypt, that of music was hereditary. Herodotus tells us that the inhabitants of Lacedæmon, who were Dorians, resembled the Egyptians in this, that their musicians were all of the same family; and that their priests, like those of Egypt, were taught medicine, and the art of playing upon stringed instruments, when they were initiated into the mysteries of religion. The same author mentions that in the processions of Osiris the Egyptians carried sta-

tues of the god, singing his praises, and were preceded by a flute. A singular proof of the antiquity of this art exists at Rome, on the *Guglia Rotta*, in the shape of a large obelisk brought from Egypt by Augustus, and thrown down and broken at the sacking of the city, in 1627, by the constable of Bourbon. It exhibits, among other hieroglyphics, the representation of an instrument, as here given, very like the *colacione* (a species of guitar) still in use in Naples. From the pegs it is evident that two

strings were employed; and the length of the finger-board, if the strings were tuned at a great interval from each other, would afford a very considerable scale of notes. This instrument alone proves to what extent music was cultivated in Egypt, and that its inhabitants were acquainted with the method of repeating the scale. Thoth, or the ancient Hermes Trismegistus, to whom is ascribed the invention of writing, astronomy, religious rites and ceremonies, has the credit also of having invented the lyre, with three strings. The following, according to one form of the myth, was the origin of the invention: The Nile, after its inundation on one occasion, left on retiring a quantity of dead animals, and among the rest a tortoise. The flesh soon perished and dried up, from the heat of the sun; nothing but the shell and the cartilages was left, and from their contraction they had become sonorous. Hermes, strolling on the banks of the river, struck his foot against this tortoise-shell, and was agreeably surprised by the sound it produced; and this furnished him with the first idea of a lyre. He gave his instrument the general form of the shell, and strung it with the dried tendons of animals, resembling the gut-strings of the present day. This is, however, only a Euhemeristic or rationalised version of the myth, which is given in a more genuine form in the Homeric Hymn to Hermes, and in Apollodorus iii. 10. 2.

The single flute, called *photinx*, seems to have greater claims to antiquity than the lyre itself. Apuleius, describing the mysteries of Isis, tells us the form of this instrument, as well as the manner in which it was held; and all the representations of it show that it resembled the bullock's horn. Indeed, there can be no doubt that, in the remotest period, the horns themselves were used for the purpose. But it is certain that the Egyptians had instruments much more susceptible of inflection than those of which we have been speaking; for on the ceilings and walls of the chambers of the tomb of Osymandyas, at Thebes, described very circumstantially by Diodorus, there are, among other decorations, several representations of musical instruments; one of which, from Denon, is given on the next page, for the purpose of showing the reader that the harp of the present day is in general form not very dissimilar to the instrument then in Egyptian use, and that perform-

ance upon it must have required considerable skill. Other representations of harps occur;

like the modern harp. The instruments in Abyssinia were found by Bruce to have a close resemblance to those of Egypt.

The arts which flourished in this nation at so early a period would doubtless have continued to do so under their own kings; but after the subjugation of the nation by Cambyzes, B.C. 525, a period of great depression followed. The Ptolemies, indeed, encouraged the arts; but under their reigns they were cultivated chiefly by Greeks. At a feast of Bacchus, given by Ptolemy Philadelphus, Athenæus says that the choir was composed of six hundred musicians, and of that number one-half were performers on the cithara. According to the same author, under the seventh Ptolemy, Egypt abounded with musicians; and at this period the practice of music was so common in the country, that there was not a peasant or labourer near Alexandria unable to play on the lyre and flute. The father of Cleopatra, who was the last of the Ptolemies, from his skill on the flute took the title of Auletes (flute-player), and established musical competitions in his palace, himself disputing the prize with the first musicians of the day. Such was the flourishing state of the art in Egypt up to the time of Cleopatra's misfortunes. Among the modern Egyptians no remains or traces of the ancient art are now to be found. Still they are passionately fond of music; and there are, according to Savary, to be found among them both male and female musicians who sing and accompany themselves. This author describes them as most successful in their plaintive music; to which, he says, even the Turks themselves, the enemies of art, will pass whole nights in listening.

Grecian Music.—According to the logographers, who modified the Greek myths to suit their own purposes, there came into Greece with Cadmus, the son of Agenor, a class of men well versed in the arts and sciences, and called Curetes. These established themselves in Phrygia, where they were called Corybantes; and in Crete, where they received the name of Dactyli: they spread also into Rhodes, Samothracia, and other places. In these places writing and music, we are told, were the arts principally taught by them. The legend goes on to say that Cadmus, in Samothracia, took to wife Harmonia (sister of Iasius and Panlanius), who was so skilled in

music that the Greeks gave her name to the art. Diodorus, in describing the marriage feast of the parties, makes the gods themselves guests. Hermes came with his lyre, Apollo brought a similar instrument, Athena assisted with a flute, and the Muses also brought their flutes; Electra, the mother of the bride, celebrated the mysteries of Cybele with dancing, tambourines, and cymbals. This story was probably founded on ceremonies which the priests, at certain festivals, performed in honour of Harmonia and Cadmus. It is unnecessary, however, to notice here the mythical tales which involve reference to the art of music, as not a particle of genuine history can be extracted from them.

The instruments mentioned in the *Iliad* and *Odyssey* are the lyre, the flute, the syrinx, or Pan's pipes. The lyre in the Homeric poems is called *φάρμυξ*, *κithára*, and *χέλυσ*; Aristophanes being the first Greek poet who calls it *λύρα*. In the Homeric poems music and poetry are inseparable: *αοιδός*, a singer, being the word used to express a poet. In the eighth book of the *Odyssey*, Demodocus is described in his character of poet and singer as the glory of the human race. The poets and musicians of Greece appear to have much resembled the Celtic bards. They wandered about, singing their works in great cities, and usually found admission to the palaces of princes, where they were treated as though endued with inspiration. Burney remarks that religion only can impart permanence to any system of music; and he conjectures that the airs sung in the temples in the time of Plutarch were then of the same relative antiquity as to us is the plain chant of the hymns of the Catholic Church. Plato, Porphyry, Athenæus, and the scholiast of Pindar, speak highly of the talents of Thaletas of Crete, who is said to have founded the second of the musical schools which flourished at Sparta. If we are to credit Plutarch, Archilochus contributed more than any other to the advancement of poetry and music. Herodotus, always ready to ascribe historical sequence to mythical or semi-mythical times, makes him the contemporary of Candaules, and of Gyges, king of Lydia, 724 years before Christ; but modern chronologists place him much later. He was a native of Paros.

Without entering into particulars, it is sufficient to mention that at this period melody was strictly determined by the measure of the verse. A different set of feet in a verse necessarily required new airs in the music. Hexameter was the most ancient species of measure, and so continued till the introduction of lyric poetry. If Archilochus was the inventor of music different to that which suited the hexameter verse, he was indeed the inventor of lyric poetry, which after his time became a species of versification totally distinct from that of the heroic. Archilochus is supposed to have been one of the first conquerors at the Pythian games. Tyrtæus, who was a soldier as well as a musician, was celebrated for his military

MUSIC

songs or airs. The scholiast of Horace makes the Lacedæmonians indebted to him, during the Messenian war, for a victory in a battle, in which he led them on to the sound of the military flute, and states that for this good service they rewarded him with the rights of citizenship. The authors who have written on the progressive state of Greek music unanimously celebrate the talents of Terpander; but neither the exact time of his appearance, nor the place of his birth, can be ascertained. Many have given him the credit of having added the three strings to the lyre: it is said, however, that he was the first who used the seven-stringed lyre among the Lacedæmonians, by which he gave great offence to the people. The Spartans disliked innovation, and Plutarch relates that the Ephori fined him for his invention. The Arundelian marbles state that he obtained the first prize in music at the games instituted at Sparta to avert the anger of Apollo for the murder of one of his priests by the Dorians. Plutarch says that no other proof of his skill could be wanting, seeing that his name appears four times on the register of the Pythian games, where he carried off successively four of the prizes. At the Grecian games music formed a principal part of the ceremony: the combats were to the sound of music. In the dramatic representations, the declamation was accompanied by an orchestra, and there were moreover particular prizes allotted to the professors of the art. At first music had but little share in the Olympic games, but at a later period prizes were given to successful competitors in this art. It is well authenticated that, at a comparatively late period, Nero appeared at them, and of course carried off the prize. The Pythian games, founded in remembrance of Apollo's mythical victory over the serpent Python, were at first confined to poetical and lyrical contests; but in these music was afterwards admitted to a share of the prizes; and, in the year 559 before Christ, a crown was decreed to the best performer on the lyre, or, rather, on an instrument with strings. The prize was nothing more than a laurel crown, in memory of the love of Apollo for Daphne; though afterwards the apple, a fruit consecrated to Apollo, was added. At these games a peculiar musical composition was performed, of considerable length, in allusion to the contest of the god with the serpent: it was composed by Sacadas, and sung for the first time by him at Delphi. Among the musicians and poets who distinguished themselves at these games were Alcman of Sardes; Alcæus of Mitylene, the contemporary of Sappho (to the latter of whom Aristoxenus and Plutarch attribute the invention of the Mixolydian mode, of which Plato, the advocate of simplicity in music, much complains); Minnermus, famous for his performances on the flute, in the sixth century before the Christian era; Simonides, born at Ceos, 538 B.C., the master of Pindar, who was born at Thebes.

in Boetia, about 520 years before our era. At the Nemean games, which took their name from Nemea, a village in Arcadia, the contests were somewhat similar to those at the Olympic games, and it is known that those in music formed a portion. It was at these games that the musician Pylades, of Megalopolis, sang, accompanied by the lyre, an air composed by Timotheus, in which the words were so suited to the circumstances of the battle of Mantinea, that the audience immediately turned their eyes to Philopæmen, who was present, and interrupted the singer by shouts and acclamations of applause. Timotheus, born at Miletus, 446 B.C., was one of the most celebrated poets and musicians of antiquity. Pausanias tells us that to the seven strings of the lyre he added four more; though Suidas says that he added but two, the tenth and the eleventh: for which innovation he was banished from Sparta, and ordered to cut off the additional strings, that he might not corrupt the ears of the youth with too great a variety of notes. This Timotheus, who died two years before the birth of Alexander, must not be confounded with the celebrated flute-player who was so great a favourite with that prince, and whose tones animated him to arms. The Isthmian did not differ from the games already described: they received their name from being celebrated on the isthmus of Corinth. Other games existed in different cities, as, for instance, the Panathenæic at Athens. Music was cultivated at all, and held in much esteem.

At Athens, in the time of Pericles, music was considered so necessary a part of education, that not to understand it nor play any instrument was considered a disgrace. Pericles was especially zealous in his patronage of music. Besides regulating the form and increasing the number of musical competitions at the Panathenæic festivals, he built an edifice called the Odeum, for the express purpose of rehearsals previous to performance in the theatre. It was during his era that Antigonides and Dorion, the two most eminent flute-players, flourished. So great appears to have been the passion for flute-playing, that as much as three talents (upwards of 600*l.*) were given for a single flute. Women also were performers on the flute. Of these the most renowned was Lamia, to whom, for the benefits she had prevailed on Demetrius to confer upon the city, the Athenians dedicated a temple, under the name of Aphroditè Lamia. It seems that execution on this instrument was carried to a great extent; for Aristotle cries out against the difficult passages that used to be practised, and even against music generally. The people, however, who, as a mass, are never disposed to give up the pleasures of sense for those of the mind, continued to encourage these novelties and their authors; and, from being the handmaid, music became the mistress of poetry. The justice of the complaints of Plato and Aristotle on this point is confirmed by Aristoxenus himself, well skilled in the art; and Plutarch frequently

MUSIC

laments that the theatre had ruined music. After the complete subjugation of the Greeks, music, like the rest of the arts, fell into decay. They continued, indeed, to cultivate music under the Roman emperors, and under their own: even afterwards, under the Turks, it was one of their amusements; but so barbarous is it in the present day, that it is difficult to conceive that the same nation ever possessed a music which drew down the plaudits of thousands. To form any idea of the ancient Greek music is now just all hope: materials upon which we could judge have long since passed away; but we will add, in conclusion to this section, the opinion of M. Ginguené on the subject. 'We see in the poetical works of the Greeks the variety and liveliness of their passions, and these same passions could not be expressed in music without an equal variety of air and modulation. I do not mean by that to say that Greek music was entirely similar to our own: to decide that point it would be necessary to hear and compare the one with the other. I maintain only that Greek music was full of harmony; that it admitted that variety of modulation which alone can give pleasure to cultivated minds; and that to suppose that the Greeks were pleased with a music that comprehended but four notes is one of the greatest follies that can be imagined.'

Roman Music.—Strabo and Livy affirm that the public music of the Romans, as used at sacrifices, was learnt from the Etruscans. Servius Tullius, in his alleged division of the people into classes or centuries, is said to have directed that two entire centuries should consist of trumpeters, horn-players, and those who sounded the charge. One hundred and fifty years afterwards, the marshal at funerals was, by the laws of the twelve tables, directed to provide six flute-players. Among the Romans, as was also the case with the Greeks [see above], music and the drama were inseparable. In the end these exhibitions became offensive; but the further notice of these is unnecessary in this place. Music, however, was for a long period confined to sacred uses; and it was only after the defeat of Antiochus the Great that the Asiatic custom was introduced of having female musicians—*psaltria*—to play at festivals and private banquets. The Etruscan music was cultivated with success; for all the instruments of the Greeks, which are known to us from their bas-reliefs, are to be found in paintings on Etruscan vases: so that it may be safely assumed that the Romans were accustomed to the best music that the age afforded. Under Augustus, who was not a great patron of the art, music was not much esteemed. Tiberius banished musicians from the city, which under him became as sad as in the days of Augustus it had been lively. Caligula, however, recalled them. Claudius, though he patronised gladiatorial fights in preference to music, still encouraged the art; but under Nero it shone in all its ancient splendour. Such was this emperor's delight in it, that he

passed a great portion of his time in taking lessons of Torpus, the most skilful harpist and lyrist of his day. Nero's successors were patrons of the public games, and of dramatic and musical exhibitions throughout the empire. N Adrian had always been attached to the arts of Greece. He instituted new games, which his successor Antoninus continued. Commodus, whose disposition was similar to Nero's in cruelty, resembled him also in an intense passion for the stage, on which he delighted to appear as a singer and dancer. The fall of the empire necessarily induced the fall of the arts, and music, of course, among the rest: in short, it disappeared with them—with them to spring into new life and surpass all its former glory, after centuries had passed away, and all art seemed to have been lost for ever.

Italian Music.—Italy has been to the rest of Europe in modern times what ancient Greece was to Rome. Though we cannot so well trace the art of music in its early restoration as we can the arts of design, we know that to the religion and church which brought them forward we are indebted for the foundation of all that is good in the musical art. The plain chant of the Catholic Church is said to owe its origin to St. Ambrose, Archbishop of Milan, in the fourth century. He, it is generally understood, brought it into form and based it upon rules, and two centuries afterwards it was considerably amplified and improved by Gregory the Great, who introduced the kind of music known as Gregorian, and which is still used in the service of the Roman Catholic Church in all countries. The music of Italy, aided by a language which Metastasio called *musica stessa*, notwithstanding the revolutions which it at first underwent, at length became the guide for the rest of Europe. Even out of the church, as early as the thirteenth century, music was cultivated; for Prince Conrad, in 1268, went out against Charles I. of Sicily with a female choir accompanied by cymbals, drums, flutes, violins, and other instruments; and it is known that all the courts of Italy were filled with musicians, for the amusement of their sovereigns. At Florence is still in existence a manuscript collection of sacred songs, entitled *Laudi Spirituali*, in honour of God, the Virgin, saints and martyrs, which as early as 1310 used to be sung by a society called the *Landisti*. A society of this sort existed when Dr. Burney was at Florence in 1770; and he states that he often heard them singing about the streets in three parts, accompanied by a portable organ. When Petrarch was crowned with laurel at Rome, in 1341, music was introduced to grace the ceremony; and from the account of that ceremony, printed at Padua in 1549, it appears that it consisted of instrumental as well as vocal music. It appears that, in 1022, Guido, a Benedictine monk of Arezzo, was the first who imagined the scheme of designating by points, distributed upon lines and spaces, the different sounds of the octave. The French, however,

claimed the credit of this invention for Hubald and Odo a century before the time of Guido.

Guido gave to the notes the names *ut, re, mi, fa, sol, la*, taking them, it is said, from the first syllables of words in the first stanza of the hymn of St. John the Baptist, in which they are certainly found:—

*Ut queant laxis resonare fibris,
Mira gestorum famuli tuorum,
Solve polluti labi reatum.*

The syllable *si* was afterwards added by a musician called Le Maire. From a manuscript in the Vatican dedicated to Charles, king of Sicily, above mentioned, it appears that Marchetto of Padua had improved the art; for the MS. proves that he was acquainted with dissonances and chromatic counterpoint. That the science was making vast strides from the old plain chant is clear from the bull of Pope John XXII. in the early part of the fourteenth century, wherein complaint is made of what he was pleased to call the abuse of descant, by which the principles of the antiphonal and gradual had fallen into such contempt that the singers could no longer recognise the foundations upon which melodies were established, and that it exceeded the bounds which the ecclesiastical tones prescribed. Without particularising the steps by which it continued to advance, the *Ars contrapuncti* of John de Muris, in 1330, laid down laws of harmony, some of which are observed in composition at the present hour. He says that, in the scale of the octave, there are six species of consonances—three perfect and three imperfect. Of the first sort are the unison, the octave, and the fifth; of the second sort, the two thirds, major and minor, and the sixth major. It is curious that he did not place the minor sixth among the number of consonances, since it is but an inversion of the major third, which he admits to be a consonance. Prosdocimus, in 1412, speaks of the fourth, of which no mention is made by De Muris, and treats it as a dissonance; though, he says, it is less so than the second and the seventh, and that it may be placed in a middle class, between consonances and dissonances. Advanced, however, as the science became at this period, it was not until the middle of the fifteenth century that the laws of harmony were fixed on the foundation that still bears the superstructure of the refined combinations of even modern music. The first treatise on music was printed in Italy towards the end of the fifteenth century, by John Tinctor; but that published a few years afterwards, by Franchino Gafforio (printed in 1496 at Milan), excelled its precursor. The claim of the Italians to the invention of counterpoint has been disputed in favour of the Flemings, and also of the English. There is no doubt that the former contributed much to its advancement and perfection; but the works extant, if we are to judge from them, satisfy us that the claim cannot be maintained. In the compositions of this period there is a want of melody

which all their display of science and curious combinations could not atone for; but in the sixteenth century melody and counterpoint were united by the splendid genius of Palestrina, and some of his contemporaries and disciples; and the art was enriched by the treatises of Peter Aaron, Zarlino, Artusi of Bologna, the Venetian Zaccani, and many others, which spread throughout Europe, and left scarcely more to be desired on the first principles of music as a science. Palestrina, the principal cause of this revolution, began his career by a diligent study of the masters who had preceded him, making himself familiar with their difficulties and with their styles. Applying himself to the simplification and purification of harmony, and to the discovery of more flowing and natural melodies, he nevertheless paid a degree of homage to the preceding school, whose pedantry and obscurity he knew how to correct.

The Gothic style of composing masses and motetts on a canto fermo, which he practised in his early compositions, he entirely abandoned after 1570. His style, upon which he was continually refining, became at last the model of the age; and after his time, for a considerable period, the best ecclesiastical compositions were honoured by being called *alla Palestrina*. Nanino, his fellow student and intimate friend, Cifra, his disciple Luca Marenzio, and many other masters of the Roman school, gloried to tread in his steps; whilst Zarlino at Venice, Costanzo Porta at Padua, Orazio Vecchi and Monteverde at Mantua, Bottrigari and Orturi at Bologna, endeavoured, and with considerable success, to build their counterpoint with the clearness, purity, and elegance of the great master of modern music. Among these Monteverde is particularly to be noticed, for his passing beyond the master whom he followed. He was the first who used double discords, such as the ninth and fourth, the seventh and ninth, and the seventh and second; as also the unprepared false fifth and seventh. This at the time created great disputes in the republic of music. Monteverde, in prefaces and letters, defended his practice; but his best defence was to be found in the progress made by him. The licenses he took, far from being offensive to the ear, were soon adopted by others who had abused them. The passion for fugues, canons, and other difficult compositions of that nature, requiring the highest degree of science, continued in the seventeenth century, which produced many learned musicians. One of the most extraordinary of these was Francesco Soriano, who published 110 canons upon the hymn *Ave Maris Stella*, for four, five, six, seven, and eight voices; but Pietro Valentini went far beyond him, and has left, it is to be apprehended, all future canonists in a hopeless condition. He wrote one to the words *Illos tuos miseras des oculos*, &c. resolved in more than two hundred different ways, for two, three, four, and five voices; another for ninety-six voices; a third for twenty voices only, but

with four different subjects going at the same time. Other masters employed themselves in a similar manner. Of the Roman school, also, Luca Marenzio merits special mention here: though great in church music, he is best known and admired for his exquisite madrigals, which still continue to be performed in this country. Marenzio died at Rome, in 1599. At the head of the Venetian school, the Italians themselves place Adrian Willaert, a Fleming. To him Zarlino attributes the invention of composition for more than one choir. He was maestro di capella of the church of St. Mark at Venice. His works are voluminous: his disciples were Cipriano Rore, Zarlino, and Costanzo Porta. The Neapolitan school, one of the most celebrated in Italy, was established in the fifteenth century, under the reign of Ferdinand of Arragon, a great patron of all the arts. It was at Naples that Gafforio and Tinctor, whom we have before mentioned, Guarnerio, and many others, distinguished themselves. Church and madrigal music there flourished. In the latter branch, Carlo Gesualdo, prince of Venosa, showed in an eminent degree the powers of that style of writing. The Lombard school registers the names of Costanzo Porta, its head; Gastoldi, Giuseppe Biffi, and Paola Cima, of Milan; Pietro Pontio of Parma; Orazio Vecchi of Modena; and Claudio Monteverde. The most celebrated disciples of Porta were Balbi and Piccioli. Orazio Vecchi was among the first composers of dramatic music, and for a considerable time maestro di capella at Mantua. The Bolognese school comprises few writers in the sixteenth century, though in the century following its professors equalled those of the first rank throughout Europe. Andrea Rota may be considered the head of it. Florence in music seems to take no distinguished place: we know only of Alessandro Striggio and Francesco Cortuccia as enjoying much reputation.

Dramatic music appeared in Italy in the fifteenth century, a musical tragedy having been acted at Rome in 1480; but the real epoch of the music of the drama can scarcely be dated before 1597, and its first appearance was at Florence. Ottavio Rinuccini is recorded as the poet, and Peri as the musician, both Florentines, and the name of the piece *Daphne*. This priority is, however, disputed in favour of Vincenzo Galileo, the father of the celebrated astronomer, who, desirous of recovering the musical declamation of the Greeks, imagined a recitative applied to the episode of Ugolino in Dante. Up to the middle of the seventeenth century the drama was principally recitative, when, in 1649, Cavalli began to introduce more airs than had hitherto been used, a practice further extended in the *Doria* of Cesti, composed in 1663; after which, for some time, it degenerated so much into *spectacle*, that, in the works represented about the end of the seventeenth century, neither poet, composer, nor singers are recorded, but the machinist and decorator only. Among the composers

were, however, men of great knowledge and genius, such as Gasparini, Pertti, Colonna, Lotti, and Alessandro Scarlatti, who is said to have been the inventor of the obligato recitative. Great improvements were introduced in the beginning of the eighteenth century by the pupils of Scarlatti; viz. Leo, Vinci, Sarro, Hasse, Porpora, Feo, Abos, and particularly Pergolese. About the middle of the century appeared Jomelli, Piccini, Sacchini, Guglielmi, Traetta, Anfossi, and others, whose names are not less celebrated than their predecessors, and the century closes with Paisiello and Cimarosa. It remained, however, for a Bohemian, Gluck, to accomplish the revolution which has brought the opera to its present state in Europe.

Europe is as much indebted to Italy for the introduction of instrumental as for that of vocal music: the Italians have been the instructors in both. Violin music was cultivated by Corelli and Tartini, and their pupils, before other nations had thought of it; and the same may be said of the harpsichord, from Frescobaldi to Clementi. So, in concerted pieces, Boccherini introduced the quintett; and indeed, short of the symphony, which we owe to the Germans, their early superiority cannot be disputed. In our time a sensible decay is visible in Italian music; the art seems to have left its ancient seat to abide in Germany, where it has been cultivated with astonishing ardour and success.

German Music.—The Germans owe their music to the Italians. They received the Gregorian chant from Italy; and, though they may not have equalled their masters in vocal melody, they have greatly surpassed them in instrumental music. It is certain that, at the beginning of the seventeenth century, the music of Germany was greatly inferior to that of Italy; and it was not till the end of this century that the Germans began to evince high and successful talent for the art. We are not acquainted with any of the earlier music of the German church—similar in character, we mean, to that produced by the school of Palestrina in Italy; but in later times the writings for that church, by Graun, Haydn, and Mozart, have become highly popular. In the madrigal style we believe they exhibit no specimens, which is the more remarkable, from the circumstance of the German school having been considered by some to have been of as early an origin as the Flemish. The oratorios possess the greatest beauties: we need only name the *Passions Musik*, by Bach; the *Messiah* and *Israel in Egypt*, by Handel; the *Creation*, by Haydn; and *Eljah*, by Mendelssohn. Though not so old as that of Italy, the German theatre is nevertheless of early origin; but until Keyser appeared to compose for the theatre at Hamburg, about the end of the seventeenth century, it was without celebrity. During the whole of the last century, the German composers bred in the Neapolitan school carried their style into Germany, where it became the model of

MUSIC

the country. John Adolphus Hasse had the principal share in the transference of this style, which, improved by Graun, Neumann, Glück, and carried still further by Haydn and Mozart, has travelled back to Italy, to shine in Rossini and others, though Meyerbeer, a German, stands in the highest rank among modern opera writers. Glück, though by birth a German, belongs properly to France; for, strange to say, he was not properly appreciated by his own countrymen, though in later years they found out their error, and acknowledge it still by the rapture with which his works are now received. Germany derives its greatest reputation from the success with which it has cultivated instrumental music, particularly the grand symphony, in which the science and art of music put forth their highest powers. Haydn, Mozart, Beethoven, Mendelssohn, and Spohr are the greatest writers of this high style of composition, as well as of other allied forms of instrumental music, as the quartett and quintett, the concerto, &c. In harpsichord and pianoforte music, it may be safely said they have surpassed all other nations; for it would be difficult to find names in that respect of equal reputation with those of J. S. Bach, of Handel, Mozart, Düssek, Cramer, and a host of others, culminating in the giant Beethoven. The music of wind instruments seems to belong almost exclusively to Germany: their organists are excellent, and their orchestras well regulated. In musical literature they are superior to every other nation: witness the works of Fux, Matheson, Marpurg, Kirberger, E. Bach, Albrechtsberger, Forkel, Koch, and a host of others, most of them of the eighteenth century. In the present day, it is by no means surprising that the success of the Germans should be so extraordinary, seeing that there is no school for the education of youth in the country at which music is not taught and cultivated, even down to those where children receive gratuitous instruction.

Flemish Music.—The Flemish have been frequently confounded with French musicians; so that it is rather difficult to separate, at times, the one from the other. Louis Guicciardini (*Descrizione di tutti i Paesi Bassi*, published 1556) gives a list of all the musicians born in the Low Countries, and at that time dispersed in different parts of Europe, which robs the French catalogue of some of its most distinguished names. From the fifteenth century Flanders, from its commerce, wealth, and superfluous riches, was enabled to patronise the fine arts, especially in the times of Charles V. and Francis I. These monarchs, who lived less in their own capitals than elsewhere, seem to have carried the arts with them wherever they went; and when we recollect their frequent sojourns at Brussels, Antwerp, and other cities of Flanders, we are not surprised at the number of excellent musicians that Flanders produced. John Tinctor flourished about 1474: he was a native of Flanders, and maestro di capella to Ferdinand of Arragon,

king of Sicily and Naples. He is the earliest theoretician whose name has reached us. Soon after, or contemporary with him, was John Okenheim, the first composer of music in parts. From the fragments which have been preserved by Glareanus, he appears to have been a learned writer, whose works seem more calculated to please the eye than the ear; and from the authors of the following century who notice him, we learn that he was the writer of a motett in thirty-six parts. Josquin des Prés, or, as the Italians call him, Josquino del Prato, was Okenheim's most celebrated scholar. The laws and difficulties of canon, fugue, augmentation, diminution, inversion, and other practices of church music, were by him observed and overcome in the most felicitous manner; and he has by some been dignified with the title of father of modern harmony, inasmuch as his era is nearly a century before that of Palestrina, Orlando, di Lasso, &c. It is proper to state that Guicciardini claims Josquin as an Italian; and, at least, there can be no doubt that he was educated in Italy, inasmuch as he was a singer in the chapel of Sextus IV. His compositions were extremely numerous, and as often executed in the beginning of the sixteenth century as those of Handel were in England fifty or sixty years ago. His death took place at Brussels; and his monument is still to be seen in the church of St. Gudule. Hobrecht, or Obrecht, was a good composer of this period, and adds to his talent the honour of having been selected by Erasmus to instruct him in the principles of his art. We must pass shortly over the names of Pierre de la Rue, or Petrus Platenis, as he was sometimes called, Jean Mouton, Verdelot, Nicolas Gombert, maestro di capella of Charles V., Jacques de Wert, Pevernage, Lupi, Waelrent, or Waelrent, Verdonk, Arkadelt, and others, many of whom are still known to the musical antiquary by their madrigal compositions, though they were called only *songs for parts* in Flanders. Between 1544 and 1555 more than twenty collections of these *chansons* or madrigals were published at Antwerp and Louvain, by Tylman, Susaro, and Pierre Phalaise, who were themselves good composers; as were, in the same century, the publishers Rhau at Wittenberg, Gardano and Scotto at Venice, Ballard in France, and Tallis and Bird in England. After Clemens (non papa), an elegant and exquisite, though not voluminous writer, and Cypriano Rore, a pupil of Adrian Willaert, must be recorded the name of Orlando di Lasso, one of the most diligent and celebrated writers of the sixteenth century. He was born at Mons in 1520, and died at Munich in 1593. Living to a great age, the number of his works exceeds those even of Palestrina. Fifty collections of his different works are still extant, consisting of masses, motetts, passions, psalms, and songs or madrigals, printed in Italy, Germany, France, and the Low Countries. Such was his reputation, that the following verse was written for his epitaph:—

His file Orlandus Lassum qui crocrot on bem.

Gringuené, speaking of Cypriano Rore and Orlando di Lasso, says, 'These two Flemings, having passed the greater portion of their lives in the courts of princes, had acquired a lighter style, and a species of melody more appropriate to secular music, than that of Palestrina, who, residing at Rome, and writing principally for the church, exhibits in all his productions a gravity belonging to the species.' And again, 'They were two masters of harmony; and, the church excepted, they prepared the colours and set the palettes of musicians with many new tints of harmony and modulation, which were exceedingly serviceable to those who came after them.' These were the first masters who ventured upon chromatic passages, and upon accidental flats and sharps. From the epoch of, these men, Flanders ceased to have a school of music especially belonging to itself.

French Music.—Hubald de St. Amand and Eudes de Cluni have been named by the French writers as having preceded Guido in the knowledge of the scale; but, without venturing to decide between the claimants, it may be safely said that France, as respects the art and science of music, was much advanced at a very early period, and that the country certainly boasted of many church musicians between the eighth and eleventh centuries; for besides the two already named, we have Remi, a monk of St. Germain d'Auxerre, Gerbert le Scholastique, and others whose knowledge is well authenticated. In the fourteenth century Philippe de Vitry, archbishop of Meaux, applied himself to music and poetry with considerable success. A manuscript preserved in the Vatican proves him to have been well informed upon counterpoint, as far as it was then known and practised; he not only applied himself to church music, but wrote motets; but these are lost, and perhaps would, if we had them, be difficult to decipher. Belonging to this century, also, we have, by the assiduity of the Abbé le Boëuf, the account of a manuscript by Guillaume de Machau. This MS. consists of two volumes of French and Latin poems, and a great number of *lays*, *virelays*, *ballades*, and *rondeaux*, all set to music; some for a single voice, others in three and four parts—triplum, tenor, contra-tenor, and a part without title. In the second volume is an entire mass, including the *Credo*, in four parts, which it is believed was sung at the coronation of Charles V. in 1364.

During the fifteenth and sixteenth centuries, the art made but little progress in France. Under Francis I. musicians in France were much less numerous than in Italy, Germany, England, and the Low Countries. The works of Claude de Jeune, who probably ought to be placed with the Flemish school, and of Orlando di Lasso, seem to have been admired and performed at this period in the country in which Josquin was also a favourite. The dearth of writers on the science at this period is no less remarkable. There is, however, one singular

work of this period, by Clement Jaunequin, entitled *La Bataille, ou Défaite des Suisses à la Journée de Marignan*, in which imitations of the sounds of battle occur. He published a collection in 1544, called *Inventions Musicales à quatre et cinq Parties*. The masters about this period were Didier Lupi, Guillaume Belleu, Philibert Jambé-de-fer, Sauterne, and Noël Faigent. It is remarkable that some, of the worst tyrants have been great patrons of music and its professors; to Nero and our Henry VIII. may be added, for France, Charles IX. At the end of the sixteenth century were some minor artists, such as Jean de Castré, Louis Bisson, Nicholas Duchemin, Francois Roussel, Jean Peroin, and others, who have left collections of madrigals. Francois Eustache de Caurroy, born in 1549, called by his contemporaries *le prince des professeurs de musique*, was maestro di capella to Charles IX., Henry III., and Henry IV., and enjoyed considerable reputation; his works, however, are but little above mediocrity. Jacques Mauduit was a similar instance of mediocrity rising into celebrity. He composed the requiem for the funeral of the celebrated Ronsard, which was afterwards performed at that of Henry IV., whose reign was too short to allow the arts of peace to make much progress in France. His son, who came to the throne at the early age of six years, was a great friend to music, and appears to have kept up what might be called a considerable band for that period. During the reign of Louis XIII., Jean Baptiste Boesset wrote several part songs, as they were called. About the middle of the seventeenth century, Michael Lambert, who died in 1696, appears to have attracted many scholars by his skill in composition. Dramatic music was introduced into France about 1645. In 1660, at the celebration of the marriage of Louis XIV., the opera of *Ercole Amanti* was produced, and the foundation of the French opera was thus laid. At this period Lulli, of Florentine birth, had been patronised by the chevalier de Guise, through whose offices he was put under the best masters of the time. Till the year 1686, in which his last opera was brought out, he seems to have been the idol of the court, and to have been considered in France the ne plus ultra of composers. Compared, however, with the Italian opera of the same epoch, his compositions are not far behind, though it was a misfortune for the country that, for so long a period, everything which was not an imitation of the style of Lulli was considered an inferior production. Instrumental music made but little progress in the seventeenth century. The most distinguished organists were, the three Bournonvilles, and the three Couperins; Charbonnières, who died in 1670; Dumont, a good composer of church music, who first introduced violin accompaniments into France; the Abbé de la Barre; and, lastly, Lalande, the most celebrated French composer of ecclesiastical music, at the end of the seventeenth

MUSIC

and beginning of the eighteenth century. Rameau, born at Dijon in 1683, was destined to rouse the French nation, which seemed to have slept since their loss of Lulli. In the space of twenty-seven years after 1733 he produced twenty-two operas, and became so great a favourite with the people that it was dangerous to criticise his works. The time has, however, passed in which his operas would be listened to; and but for his theoretical works, the only solid base of his glory, he would long since have been forgotten. Rameau died in 1767. His school lasted till about 1775, though since 1750 the comic opera has been on the Italian model. Under this, with Dauvergne, Le Borde, Floquet, J. J. Rousseau, Duni, and Philidor, French melody has regenerated; and Monsigny, Gossec, and Gretry completed its improvements. The reform thus effected prepared the French for the reception of the *Iphigénie* of Gluck, in 1774, at which time he had Piccini and Lucchini for rivals. These musicians have been succeeded by a school which comprises the names of Berton, Mehul, Boieldieu, Kreutzer, and others; and among the Italians who joined their ranks are found those of Cherubini, Spontini, and Winter. In instrumental composition the French have not been so original, though latterly they have considerably advanced, and the names of Auber and Berlioz will at once occur to the reader as great in this department. France is considered deficient in musical literature, and does not attend to its cultivation with the ardour of the Italians and Germans. Their *Conservatoire*, however, is an establishment likely to do honour to the nation; and the work of Choron, entitled *Principes de Composition des Écoles d'Italie*, is alone sufficient to redeem the French from the accusation of wanting musical literature.

English Music.—We are not acquainted with writers in this country of earlier date than those of Italy; but, for the honour of this country (however much we may have been behind Italy in the restoration of other arts), in that of music we were formerly quite on a par with the Continent; and it is singular that in later years we should have lost, and perhaps deservedly, our character among other nations. It is certain that England can boast masses in four, five, and six parts, written by natives, as ancient as those of the Italians themselves; we have also secular music in two and three parts, and in good counterpoint, in the latter part of the fifteenth and beginning of the sixteenth century, about which period the names of William of Newark, Sheryngham, Turges, Tudor, Banester, Browne, and others, are familiar to the English musician. The first named was one of the musicians of Henry VI.; and the compositions of Tudor are known from Prince Henry's (Henry VIII.) music-book. Henry VIII. is known as a composer, from a beautiful anthem in Boyce's collection of cathedral music; and his patronage of Christopher Tye, the composer of *Laudate Nomen Domini*, a motett

frequently sung at madrigal meetings in the present day, shows that good music was then esteemed as it ought to be. Marbeck, in 1550, published the whole of the reformed cathedral service to musical notes, and for his exertions as a reformer was nearly being brought to the stake. During the reign of Elizabeth the talents displayed by our countrymen appear to have been surpassed in no other country, and music here was then indeed in its palmy state. Tallis, Bird, Morley, Dowland, and Bull, were the principal composers of the reign: Elizabeth herself must have been no mean performer, if she was able to play the pieces in her virginal book. Though it does not appear that James I. took much delight in music, it nevertheless continued to prosper during his sway; indeed, the compositions of Gibbons were, as pieces of church music, perhaps never surpassed in any age or nation: neither are his secular pieces of inferior character. This reign as well as the preceding was fruitful in madrigal writers as well as composers for the church; among the former were Michael and Thomas Este, Bateson, Ward, Litchfield, Pilkington, Wilbye, Bennett, Farmer, Ford, and others; and among the last Tomkins, Elway Bevin, and Dr. Nathaniel Gyles. In the time of Charles I. instrumental music was coming into vogue: the monarch was a pupil of Cooper (who was wont to be called Coperario), and used to practise the viol-di-gamba. He had a band of performers, eighteen of whom are known, including Nicholas Lanier, the master of it. The most celebrated musicians of this reign were Dr. Wilson, William and Henry Lawes, and Dr. Child, who died in 1697, aged ninety, after having been organist of St. George's chapel, Windsor, during the extraordinary period of sixty-five years. So intent was Charles upon advancing music, that he granted a charter to the most eminent musicians of that day, with many great privileges. The art had been sinking for some years, but its fall was accelerated by the suppression of the cathedral service in 1643; and the only persons of whom we hear during the time of Cromwell were William and Henry Lawes. Though these men were favourites of Milton, and the subject of some of his verses, they were sadly inferior to Tallis, Bird, and Gibbons. During the interregnum the musical flame was chiefly fed at Oxford; but even there, from the year 1616, in which the king was forced to leave the city, after the battle of Naseby, until 1656, it was nearly extinguished. At the Restoration it appeared again to flourish: Child, Christopher Gibbons, Rogers, and Wilson, were made doctors of music at Oxford; the choirs again obtained good masters; and the organs, which had been destroyed by the rage of the Puritans, were again set up, though with difficulty from the scanty supply of organ-builders. Among the musicians who were attached to the court of Charles II. was Henry Purcell, of whom Dr.

MUSIC

Burney says, that he, 'during a short life, and in an age almost barbarous for every species of music but that of the church, manifested more original genius than any musician, under similar circumstances, that any enquiries into the history of the art have yet discovered in any part of Europe.' This truly great man died Nov. 21, 1695, in the thirty-seventh year of his age; his principal contemporaries were Dr. Blow, his master, Pelham Humphreys, and John Weldon. After Purcell's death, some skilful men appeared as amateurs in the service of the church; namely, Doctors Holder, Aldrich, and Creighton: among the professors were Jeremiah Clarke, Goldwin, and Doctors Croft, Green, Boyce, and Nares. Croft of all these was undoubtedly the greatest; he, like Purcell, was a disciple of Blow: always elegant and simple in his strains, frequently grand and masterly, he has not left a composition that does not exhibit great learning. His death occurred in 1727, in the fiftieth year of his age. Dr. Boyce occupied the void which Croft's death had created; he was a good musician, always pleasing, but rarely grand in his compositions. His contemporary, Jonathan Battishill, wrote some fine compositions for the church, and prepared the way in glee writing for a race of English musicians who are an honour to their country. The reader will recognise the truth of this assertion when he glances at the names of Alcock, Arne, Attwood, W. Beale, Calcott, Dr. Cooke, Robert Cooke, Crotch, Danby, James Elliott, Harington, Horaley, Thomas Linley, the earl of Mornington, Shield, Stafford Smith, Spofforth, the Wesleys, &c. In dramatic and symphony writing, we regret to say, England is still in her infancy, though Sterndale Bennett, Macfarren, and Balfe are well-known names in these branches of the art.

Chinese Music.—The Chinese have had a system of music from a most remote period, and in its scale it seems to have more resemblance to the Grecian than any other to which it could be compared. From the time, it is said, of Yao and Chun, which their chronology would carry back two-and-twenty centuries before Christ, they have had what they call eight species of sounds: 1st. The sound of dried skins, such as drums; 2nd. The sound emanating from stone, called *king*; 3rd. That of metal, as bells; 4th. That of baked earth, called *hien*; 5th. That from silk, called *kin* and *che*; 6th. That from wood, called *ya* and *tihou*; 7th. That from bamboo, such as flutes, called *koan*; 8th. That from the gourd, called *cheng*. Their scale consists of fourteen notes, of which the seven middle notes correspond to our *g* at *f* upwards. They seem unacquainted with harmony.

Hungarian Music.—About the ninth century the Hungarians left Asia to settle in Europe, when they conquered the country that bears their name. Like all the Asiatics, they were attached to music, and at first, doubtless, used only Asiatic instruments: these were

nearly all wind instruments, and consisted of the trumpet, the flute, the cymbal, and several others. Till the time of Mathias Corvin it was in a state of mediocrity. Under Ladislas and Louis II. music was cultivated with great care; their national songs were, however, their only vocal music till the time of Stephen, king of Hungary, when the ecclesiastical chant appears to have been introduced. From a diploma of Bela III., A.D. 1192, that prince, it appears, sent an envoy to Paris to be instructed in melody; being induced to do so, perhaps, by his second wife Margaret, who was daughter of Louis VII. of France.

Theory and Practice of Music.—Music is both an art and a science. Its study comprises three distinct branches: namely—

1. The science of *acoustics*, treating of the philosophical nature of musical sounds, and of their relations to each other.

2. Musical *composition*, which is of itself both an art and a science. This is what is usually understood by the *theory* of music. And,

3. The art of *performing* music, either with the voice or on instruments. This is entirely of a practical nature.

The last of these can properly be studied only by personal application under the direction of a teacher, and therefore it is out of our province to notice it here, further than to say that the performance of music requires a knowledge of composition, so far as to understand perfectly the intentions of the composer; while a still further acquaintance with theory is highly advantageous in promoting the intellectual character of the singing or playing.

On the science of Acoustics, also, which is both elaborate and profound, our remarks here must be necessarily few. Musical sounds are produced by vibrations of the air, which may either be generated in the air itself, as by a flute or organ pipe, or transmitted to it by some vibrating body, as the reed of a clarionet, or a pianoforte or violin string. These vibrations may be counted, by certain philosophical means: and it is found that as they are quicker or slower, i.e. as there are more or fewer of them in a given time, the note sounds to us more acute or more grave; so that a certain note always corresponds to a certain number of vibrations per second. The position of a note in the scale of acuteness and gravity is called its *pitch*, and it follows that a higher pitch involves a greater velocity of vibration, and vice versa. It might be supposed that a general consent of musicians would have established a uniform pitch, by which any certain note might be positively defined, so as to give the notes of music a positive and definite position; but unfortunately this is not so; and consequently it is impossible to do more than define them approximately. The note called middle C on the pianoforte, and marked thus

thus c , or thus

usually assumed, in theoretical works, to cor-

MUSIC

respond to 512 single vibrations per second; and this was till late years the pitch adopted in practice, but modern custom has made it a little higher; the C now established in France has 522 vibrations, and in England and Germany 528 vibrations per second.

When two notes are sounded together, it is found that their effect on the ear has a remarkable relation to the proportion between their respective velocities of vibration; and this principle gives rise to the acoustic doctrine of intervals, which may be briefly stated as follows. If the numbers of Vibrations of two notes in a given time be as 1 : 2, the second note will be of the same name as the first, but an octave higher; so that the interval of the octave is expressed by the vibrational relation 1 : 2. If the respective numbers of vibrations are as 2 : 3, the second note will be a perfect fifth higher than the first, i.e. the interval of the fifth corresponds to the acoustical relation of 2 : 3, and so on.

Acoustical Relations of Musical Intervals.

Notes	Intervals from the Lowest Note	Ratio of Vibrations with those of the Lowest Note	Single Vibrations per Second
C 	Octave	1 : 2	1056
B 	Major 7th	8 : 15	990
A 	Minor 7th	5 : 9	950
A 	Major 6th	3 : 5	880
A 	Minor 6th	5 : 8	845
G 	Fifth	2 : 3	792
F 	Tritone	18 : 25	733
F 	Fourth	3 : 4	704
E 	Major 3rd	4 : 5	660
E 	Minor 3rd	5 : 6	634
D 	Major 2nd	8 : 9	594
D 	Minor 2nd	15 : 16	563
(Middle) C 	Unison	1 : 1	528

The above table will show these relations for all the principal intervals in the scale.

It thus appears that there is some curious analogy between an agreeable effect on the ear and a simplicity of proportion in the number of vibrations, those intervals which have the simplest ratios being naturally the most perfectly harmonious, while in proportion as the complexity of the ratio increases, the effect of the combination becomes more discordant.

When musical sounds are produced by stretched strings, it is found that if the weight and the tension of the string remain the same, the number of vibrations will be inversely in proportion to the length of the vibrating portion; so that a string half the length of another will give double the number of vibrations in a given time, and will therefore sound an octave higher. And it follows that all the ratios we have given, as to the number of vibrations, will apply *reciprocally* to the length of strings producing the notes referred to; i.e. the ratio of length of two strings to produce a note and its fifth will be as 3 : 2 respectively, and so on.

We cannot follow this subject further, but must refer for more ample information to books on Acoustics, of which Chladni's *Akustik* and Helmholtz's *Lehre von den Tonempfindungen* are the most renowned.

We now come to treat, somewhat more at length, of the second division of the subject, namely, *Musical Composition*; which comprehends, first, the explanation of the peculiar symbols used, or what may be called the language in which music is expressed; and secondly, the rules usually laid down in order to produce grammatical and effective musical composition.

All musical ideas are expressed by means of notes on a staff, i.e. five equidistant horizontal lines, on or between which the notes are placed. The gamut is a table whereon these notes are placed; and their relative situations as to acuteness or gravity of tone are ascertained by clefs. The names of the notes, as originally

MUSIC

laid down by Guido d'Arezzo, were *ut, re, mi, fa, sol, la*, the lowest of these being the gamma of the scale. He had only six notes in his scale, which he repeated in different keys, so that some notes, really the same, had different names, according to the key to which they were considered to belong. Modern musicians, abolishing this distinction, have added a seventh note to complete the octave, and have used as equivalents the first seven letters of the alphabet. The diagram given in the preceding page will exhibit a comparison between the ancient and modern modes.

From this diagram it will be seen that the bass clef, also called the F clef, makes the notes on the line between the dots \div  F, whence reckoning is made upwards or downwards; that the tenor or C clef makes all the notes on the line between the cross or horizontal bars  C; and that the treble or G clef makes all the notes on the line round which the character turns  G; and it is to be observed that these several clefs may be put on any lines of the staff notes, which then take the name F, C, or G, as the case may be. Thus,

The second, fourth, and seventh of these, however, are now no longer used. The first is used for the bass voice and all bass instruments; the third for the soprano voice; the fifth for the alto voice and the viola; the sixth for the tenor voice; the eighth for the violin and other treble instruments. The eighth and first are used for the pianoforte. The eighth is also now used for treble voices.

One of the most important ends gained by the use of these clefs is the avoidance of notes running off the staff, which they otherwise would do, and what are called *ledger lines*

would be wanted; thus,

where the lodger lines are those upon which the notes out of the staff are placed. The lines of a staff are reckoned upwards; thus the lowest line is called the first, the lowest but one the second, and so on. In the pianoforte the C nearest the middle of the instrument is the note of the tenor or C clef; the G above it to the right is the treble or G clef; and the F below it to the left is the F or bass clef note.

When to the seven primary notes (see diagram) another is added above, the arrangement is called an octave; thus,

After which if more be added, either upwards or downwards, it will be but a return to similar notes either more acute or more grave in pitch; that is, an octave above or below them respec-

tively. This, which is called the *diatonic scale*, has between its notes seven intervals, of which those between *c* and *d*, *d* and *e*, *e* and *f*, *f* and *g*, *g* and *a*, and *a* and *b* are equal, and are called *tones* or *whole tones*; whilst those between *e* and *f*, and *b* and *c*, are *semitones*. To enquire how nature has implanted on the ear dissatisfaction from any other position of these semitones in the scale of the octave, is not the object of this treatise. That it is so is certain; and the most careless whistler could not alter the scale without exertion. The scale is also divided into two *tetrachords*, from *c* to *f* and from *g* to *c*: each of these consists of two tones and a semitone. All *melody* or *air*, which is an artful succession of tones, depends on a right perception of the places of the semitones.

By the particular *form* of a note, its duration, or the length of time during which it is to be held on, is known. There are nine of these forms, which are exhibited in the subjoined table; the first three are now rarely used, though in old ecclesiastical music they are constantly met with.

The large	II	equal to two longs.	II
The long	II	= two breves	II
The breve	II	= two semibreves	II
The semibreve	II	= two minims	II
The minim	II	= two crotchets	II
The crotchet	II	= two quavers	II
The quaver	II	= two semiquavers	II
The semiquaver	II	= two demisemiquavers	II
The demisemiquaver	II		II

The notes with hooks appended to their tails are frequently grouped together; this does not alter their value, but it assists the eye in reading off the proportions of the notes.

Thus,  If

a dot be added to the right hand of any note, thus , it increases its duration exactly one-half. The duration of a note is measured by the musician from habit, and is regulated by *beating time*; that is, by the elevation and depression of the hand or foot quicker or slower according to the nature of the music performed. A musical piece is divided into *measures*, which are equal portions of time; and the vertical lines which so divide it are called *bars*; single lines taking merely that name, and the two thick ones at the end of a strain *double*

bars, thus, 

Every measure must contain a certain number of notes according to the time marked at the beginning of the movement; and that time is of two sorts—*common time* and *triple time*—in which two all others originate. Common time is that which has an even number of beats in each bar, as two, four, or eight. Those common times in which a semibreve is the measure are

MUSIC

marked by a C after the clef at the beginning of the staff; thus,  When the C has a

bar through it, thus,  it denotes a quicker measure, to be beaten in minims, whereas the simple C time is usually beaten in crotchets. It is called *alla breve*. The other characters of common time are  ,

signifying that there are two crotchets, six quavers, or twelve quavers, in the bar, of which 4 and 8 (the denominators respectively) make a semibreve. The first and second of these have two, and the third four beats in a bar. Triple time is so called from the bars being divisible into three parts: it is beat with the hand down at the beginning of the bar, raised a little in the middle, and quite up at the close of it. In this time also the denominator of the figures placed at the beginning of the staff is a fraction of a semibreve; thus, if 2 be the denominator, the measure is a minim, because two minims make a semibreve; if 4, the measure is a crotchet; and so on. Hence

 signifies three minims in a bar;  three crotchets;  three quavers. So again

with multiples of 3 for the numerator, as  nine quavers,  nine semiquavers. It is

easy to recollect that the denominator of the fraction always expresses the division of the semibreve, and the numerator the number of these divisions in a bar; but the sense of the music must also be consulted, for though, for example, $\frac{3}{2}$ and $\frac{6}{4}$ are arithmetically the same fractions, the first is triple, and the second common, time.

There is a certain stress laid on some part or parts of every bar, which is called *accent*; hence each bar or measure is divided into accented and unaccented parts: the accented are the principal, and those on which the pathos and spirit mainly depend. The beginning and the middle or the beginning of the first half of the bar and the beginning of the latter half, in common time, and the beginning or first of three notes in triple time, are universally accented parts of the measure; so the first and third crotchet of the bar are on the accented part of the measure in common time. In triple time, where the notes, as we have explained go by threes, the note in the middle is unaccented, and the first and last accented; the accent, however, on the first is so preponderant, that the last is almost accounted as though it had none. It is on account of accent that it is frequently necessary to begin a movement with only part of a measure. Thus in the Welsh tune *Griffith ap Cwan*—

(As written.)

it will immediately be seen that the alteration of the accent entirely changes

(As changed in accent.)

the character of the air. An abnormal accent is often laid on some notes of the bar which are usually unaccented; this is called *emphasis*, and its employment with skill and taste contributes much to the beauty and originality of the piece. When the last note of a bar (as in the last bar of the lower example) is connected with the first of the following bar, so as to make only one note of both, it is called *syncopation*. This is also sometimes used in the middle of a measure.

A *rest* is a pause or interval inserted when silence is required in the part to which it is written, which silence is to be preserved during the time denoted by the species of rest used. The following are the rests used:

Semibreve — Minim

Crotchet Quaver Semiquaver Demisemiquaver

In modern music it is necessary that we should use other sounds in the octave besides those of the simple diatonic scale; and an expedient is therefore wanted by which the places of the diatonic notes may be raised or depressed the value of a semitone. The former, that is raising them, is effected by placing sharps before them, thus \sharp ; and the latter by means of flats, thus \flat . If we want to restore any note that has been thus treated to its original place, it is effected by means of a natural, thus \natural . Two other characters are also used—the double sharp, thus \times , which raises a note two semitones; and the double flat $\flat\flat$, which equally depresses it. Upon keyed instruments, such as the pianoforte and organ, the sharps and flats are represented by the short black keys, and there is no distinction between $D\sharp$ and $E\flat$, and such want of distinction is an imperfection in the instrument; for there is not a strict mathematical equality between the semitones of the diatonic scale. A number of these flats and sharps placed at the beginning of a staff affects all the notes of the line or space on which they are placed, and are termed the *signature*. If, in addition to these, in the course of a movement any others occur, they are termed *accidental*, and only affect the notes which they immediately precede, and any repetitions of them in the same bar; but if in the same bar any note, after having been accidentally raised, on being repeated is preceded by a natural, such natural restores it to its original place.

The ornaments of musical melody are called *graces*; of these the principal are the *appo-*

MUSIC

giatura, the *shake*, the *turn*, and the *beat*; with the *mordente*, *beat*, *slide*, and *spring* peculiar to the Germans; those of musical harmony are the *arpeggio*, the *tremando*, &c. The *appogiatura*, which always occurs on the accented part of the measure, is a small note placed before a large one of longer duration, which it usually deprives of half its value;

thus, , wherein the small notes are appoggiaturas. Occasionally, the appoggiatura is of less duration than above stated. The shake is a quick alternate repetition of a note with the note above it, the mark *tr* being placed on the lower, and the upper one not expressed; thus,

, performed .

When there is a series of ascending or descending shakes, the Italians call it *una catena di trilli*. What the Germans call the *passing shake* is thus marked , over the

note where it is intended, thus , per-

formed . The mordente of the

Italian school is used in a similar way; thus

, performed . The

turn employs the note above and that below

in the following way, , performed

. The inverted turn, thus marked

, turns from the note below that marked

instead of above it. Turns on dotted notes are very frequently used; they are written as follows, , performed

. The beat is

the reverse of the shake without the turn, and is generally made at the distance of the semitone below; hence all the natural notes, except C and F, require the note below them to be

accidentally sharpened for the beat; thus,

,

performed . The

half-beat is most frequently used in the bass, and is very similar to the *acciatura* of the

Italians. The inferior note is struck only once, and at the same time with the principal

note; but is immediately quitted, as .

The Italians use the degree above. The German mordente is a beat commencing with the

note itself, and is either long or short; thus,

 (long)  (short). This differs from

the mordente already described by being made with the next degree below. The Italians use the degree above. The German beat consists of two small notes, forming a skip, descending one degree upon the principal

note; written thus , per-

formed . Naumberger calls

this grace a double appoggiatura. The German slide consists of two small notes, which move by degrees; written thus,

.

performed . The German

spring, like the Italian mordente, consists of two small notes, sounded distinctly; thus

.

performed . It is the

practice of the composer to mark, where necessary, the occasional alteration of these graces by sharps, flats, or naturals. The graces that belong to harmony are, the *tremolo*, or reiteration of one note of a chord; the *tremando*, or general trembling of the whole chord; and the *arpeggio*, which is an imitation of the harp, the notes of the chord being struck in quick and repeated succession.

The following characters are also used in Music: The *pause* , which, placed over a note, signifies that a long continuance of the sound is to be made on that part of the measure, and is equally effective when placed over a rest; the *repeat* , which is a sign placed to show where the performer must return to repeat the passage—the Italians call it *il segno*; the *direct* *W*, placed at the end of the staff on the line or space which the following note will occupy. The dots which are found in the inner side of bars show that the measures or bars included by them are to be repeated; thus, , shows that

these two bars are to be played twice over, the same object being sometimes effected by writing the word *bis* over them.

We have already mentioned the single and double bar; all that we have to add on them here is, that as every bar or measure contains a certain number of notes, so every *strain* consists of a certain number of measures, which are terminated by the double bar.

Expression, in music, is indicated by the following marks: The *tie*, which is a convex

MUSIC

line over \frown or a concave line under \smile two notes on the same line or space, uniting them into one. It is also used to express syncopated notes where the bar divides them. The *slur* is a similar line, used over notes not on the same lines or spaces, showing that such notes are to be played smoothly or *legato*; and in vocal music it also means that all the notes connected by it are to be sung to the same syllable. The *dash* is a small vertical stroke | placed over notes that are to be distinctly marked, or, as it is termed, played *staccato*. Sometimes, instead of this, the *point* is used, though it is mostly employed to distinguish those notes from which an intermediate effect between the slur and dash is wanted, yet uniting the one and the other;

thus, . The other marks of ex-

pression are the *crescendo* $<$, by which the sound is to be increased from soft to loud; the *diminuendo* $>$, which is exactly the reverse of the last--the union of these two $<>$ indicating that the part is gradually altered from soft to loud in the middle, and then to soft again; and the *rinforzando*, for which smaller marks of the same sort are used, $>$ or $<$, which increase or diminish the sound so marked.

In order to save time in writing and copying music, the following abbreviations are used: A single stroke placed over or under a semibreve, or through the stem of a minim or crotchet, divides it into quavers, a double stroke into semiquavers, and a triple stroke into demisemiquavers; thus, .

Another kind of abbreviation is much used in modern music, and is effected by grouping the stems of minims like those of quavers; thus, , performed .

Melody, which will be perhaps better understood by the term *tune*, is a particular succession of sounds in a single part, and is produced by the voice or an instrument. The artful manner of introducing the notes of different lengths, succeeding one another at intervals pleasing to the ear, is one of the qualities distinguishing the musician; the other being the successful accompaniment of these single sounds by others, according to the laws of harmony. The laws of harmony may be learnt, and so may certain general rules of melody; but the art of producing pleasing melodies is a natural gift, which cannot be supplied by any kind of education. Melody has two motions--either by degrees or by skips: by the former when it moves to the line or space immediately above or below it; and by skips when one or more degrees are omitted between the preceding and following note. The following example shows

each motion: .

The distance between any two notes is called an *interval*.

We have already described, in the first part of this article, how intervals are theoretically defined by the ratios of the vibrations of the notes producing them, and how they may be represented by the comparative lengths of stretched strings; but it will be as well here to add a few words of explanation of a more practical nature. It is customary to measure intervals from the lower of the two notes, and the general name of the interval is determined by the number of degrees contained between them, reckoning according to the names which the notes bear. Thus, from C to D is an interval of a second, from C to E a third, from C to A a sixth, and so on. But intervals of the same general name may have different values, and therefore different special names, as the limiting notes are severally sharp, flat, or natural; thus, from C to D \sharp is a *minor* second, from C to D \flat is a *major* second, and from C to D \sharp an *augmented* second, and so on. Referring the intervals to the keys of the piano-forte, and taking as the unit of measure the semitone, i.e. the distance from any one key to the next above or below, we have the following values:—

Name of Interval	No. of Semitones	Example
Unison	0	C
Minor second	1	C to D \flat
Major second (this is also called a whole tone)	2	C to D
Minor third	3	C to E \flat
Major third	4	C to E
Perfect fourth	5	C to F
Augmented fourth, sharp fourth, or tritone	6	C to F \sharp
Imperfect or diminished fifth	6	C to G \flat
Perfect fifth	7	C to G
Minor sixth	8	C to A \flat
Major sixth	9	C to A
Minor seventh	10	C to B \flat
Major seventh	11	C to B \sharp
Octave	12	C to C

The above fourteen intervals are given in the following synopsis:—

By inserting the semitones between these intervals, the number which we have above stated in each will be easily discovered. There are also some other intervals which occur frequently in modern melodies, and which are

MUSIC

called augmented or diminished, as the case may be; thus, the augmented or superfluous

5th  consists of one semitone

more than the perfect fifth; the augmented or

extreme sharp sixth  consists of one

semitone more than the major sixth; the di-

minished seventh  consists of one

semitone less than the minor seventh; and so on. When the lower note of any interval is placed an octave higher, or the higher note an octave lower, it is called *inversion*. Thus,

2d  is converted into a 7th 
 a 3d  " " a 6th 
 a 4th  " " a 5th 

By this operation major are converted into minor intervals, and the converse; for instance, the major third becomes a minor sixth, and so on.

There are three scales occasionally used in music: the *diatonic*, the *chromatic*, and the *enharmonic*.

The diatonic is the most simple and natural scale. It has already been described; but we may add the following example:—

Diatonic Scale of the Key of C Major.

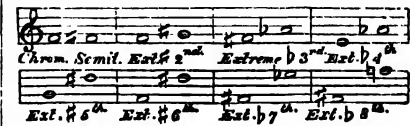

C	D	E	F	G	A	B	C
Whole tone		Semitone		Whole tone		Whole tone	

It will be at once seen that this scale, for the key of C, corresponds with the white keys on the pianoforte, no black ones being necessary to its formation.

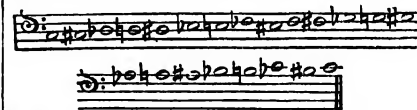

The chromatic (which, according to some, takes its name from the Greek word *χρῶμα*, colour, because the Greeks distinguished it by different-coloured characters; according to others, because, holding the mean place between the diatonic and enharmonic system, it was like colour between black and white; or, as others say, because, like colours in painting, it embellishes the diatonic by its semitones) usually ascends by sharps and descends by flats, as follows:—

From this it appears that the chromatic scale consists of thirteen notes, and it gives rise to a distinct species of intervals called *chromatic*. For example, the *chromatic semitone* is the interval between any note and the same depressed by a flat or raised by a sharp. Also, the *extreme sharp second* consists of a tone and a chromatic semitone, being composed of two degrees. Some chromatic intervals are exhibited in the subjoined synopsis:—

The enharmonic scale is a series formed by uniting the ascending and descending scale of the chromatic genus. We subjoin a diagram of it; but it is hardly to be called a scale; it is merely a list or schedule of the various notes which are to be found in the octave.

As in oratory there is a principal subject on which the speaker constantly dwells, and to which, after diverging from it, he always returns; so in music there is one sound in which the piece usually begins and ends, which regulates the rest, and to which regard must be had in all the other sounds of the piece: and this sound is called the *key*, the *key note*, or *tonic*. From the diatonic scale we have seen that the semitones lie between E and F, and B and C; the key note being C. Now if we wish to make G the key note, it is clear that without some contrivance the notation of the scale from G to its octave will throw one of the semitones out of its place; namely, that between E and F, which, instead of being, as it ought to be, between the seventh and the octave, is between the sixth and the seventh. It is obvious, then, that if we raise the natural F a semitone by means of a ♯, we shall restore the semitone to a situation similar to that which it held in the key of C. By comparing the subjoined scales, this will be more distinctly seen.

Key of C 

Key of G 

Now if D be taken as the key note, we shall find it will be necessary to sharpen the C as well as the F, in order to bring the semitones into the places which they ought to occupy in the octave; and we shall have two sharps. In order to save the constant repetition of these

MUSIC

sharps, it is usual to put them at the beginning of the staff, where they are called *signatures*, each signature denoting the key of the note written after it, thus,

In the same way the keys bearing flat are marked, saving that the note B bears the first flat, as follows:—

Besides these scales, which are all constructed with the major third, and are therefore called major keys, there is a scale, constructed from the natural notes, whose third is minor : thus,

In this scale it must be observed, first, that the places of the semitones are different; and, second, that the ascending scale always requires the seventh to be sharpened, though it is not sharpened in the descending scale. The sharp in question is, however, always omitted in the signature, and marked accidentally where the melody requires it. It must also be noted, that between the F# and G# a harsh chromatic interval, called an *extreme sharp second*, would occur; to avoid which the sixth is also sharpened, by which the scale of the minor mode has two notes different from the signature; but in the descending scale no accidentals are required.

Major and minor scales which have the same signatures are denominated *relative*. Thus the relative minor key of A is F#; in which case the tonic or key note of the minor mode is found to be the sixth note ascending of the major scale bearing the same signature; and the tonics are always one degree below the last sharp of the signature, but in flat signatures always the third degree above the last flat. Thus by sharps we have,

and by flats.

The change of a melody from its original to a higher or lower pitch is called *transposition*, and this may be effected by altering the signature according to the pitch of the new tonic or key note. *Modulation* signifies the proceeding naturally and regularly from one key to another. Every scale is immediately connected with two others: one on the fifth above, the other on the fifth below or fourth above. These were called by Dr. Boyce *attendant keys*. Minor scales have also their attendant keys, the chief one being the relative major

We here subjoin the names given to certain

notes in the scale as peculiarly marking their character. 1st. The *tonic*, or key note, is the chief sound upon which all regular melodies depend, and with which they all terminate. All its octaves above and below are called by the same name. 2nd. The *dominant*, or fifth above the key note, is that sound which from its immediate connection with the tonic is said to govern it; that is, to require the tonic to be heard after it, at the final cadence in the bass. 3rd. The *subdominant*, or fifth below the key note, is also a species of governing note, as it requires the tonic to be heard after it in the plagal cadence. It is the fourth in the regular ascending scale of seven notes, and is a tone below the dominant; but the term arises from its relation to the tonic, as the fifth below. These three principal sounds are the radical parts of every scale of the minor as well as the major. 4th. The leading note, or sharp seventh of the scale, is in Germany called the *subsemitone* of the dominant: it is always the major third above the dominant, and therefore in the minor scales requires an accidental sharp or natural whenever it occurs. 5th. The *mediant*, or middle note between the tonic and the dominant ascending, varies according to the mode; being the greater third in the major scale, and the lesser third in the minor scale. 6th. The *submediant*, or middle note between the tonic and subdominant descending, varies also according to the mode; being the greater sixth in the major scale, and the lesser sixth in the minor scale. 7th. The *supertonic*, or second above the key note, has seldom been distinguished in England by this or any other appellation.

Harmony consists in the combination of two or more sounds or melodies heard at the same moment. A *concord* is an agreeable and satisfactory relation of two sounds as respects the ear. Concord is therefore included under the term *harmony*, though harmony comprehends the agreement of a greater number of sounds than two. When two sounds heard together are unsatisfactory to the ear, the relation between them is called a *discord*. The concord then may be called a *harmonical interval*, and the discord an *inharmonical* one; yet by the proper interposition of discords the harmonies of a passage receive a lustre and value from the contrast. They must, however, as we shall presently show, be properly *prepared* and *resolved*, as it is technically called. The union of any sound with its third (major or minor) and its perfect fifth is called a *common chord*; to which if the octave to the sound be added, we have a combination of four sounds in the *harmony*; thus,

**Major**

Minor

So long as in these chords the C or the A remains the lower note, the chord is called the common chord of C or A respectively ; but the

MUSIC

moment the position of the lower note is changed, the name of the chord also changes. Thus if E of the common chord of C be used as the lowest or bass note, thus,

the chord is called the chord of the *sixth*; because the key note is then the interval of a sixth upwards from the bass note, and that sixth has for its accompaniment a minor third from E to G.

If G be now placed at the bottom and used as the bass note, thus,

the key note is an interval of a fourth above the bass, and the chord is called the chord of the *sixth* and *fourth*, as the example shows. From this it is manifest that the sixth and sixth and fourth are no more than inversions of the common chord, having the same note C for their expressed or understood bass, which is called the *fundamental bass*, because it is that on which they are founded; and the same arrangement equally exists in the common chord with a minor third. The common chord is expressed shortly thus, $\frac{5}{3}$, $\frac{5}{3}$, or $\frac{6}{5}$; but in figured bass, the omission of all figures denotes the common chord. The second example, or chord of the sixth, is merely figured with a 6; and the third example, where G is the lowest note, is denoted by the figures 4.

Of discords, the most simple is the minor seventh, or, as some call it, the *dominant seventh*; because in the natural scale it occurs only on the fifth or dominant of the key, and requires that part in which it occurs always to descend one degree. We here give its full accompaniment of four real parts:

As in the common chord either of these four sounds may be placed as the bass or lower note of the chord, yet as with C in the common chord the fundamental note of it will be G; B being a third, D a perfect fifth, and F a minor seventh; thus,

; in each of which cases it would carry the figure 7 below it. When

B becomes the bass note, as

the chord by inversion consists of a minor third, an imperfect flat or false fifth, and a minor sixth, and is, as in the example, figured 7. If D be next taken as the bass

note, thus

the chord consists of a minor third, perfect fourth, and major sixth, and is, as in the example, figured thereunder 4 or 6. If F be used for the lower or bass

note, thus

the chord is composed of a major second, sharp fourth, and major sixth, and is figured 2, or 4, or simply 2. From these observations it appears, therefore, that the last three chords are properly called derivatives of the minor seventh when accompanied with a major third and perfect fifth.

Besides the chords within the compass of the octave, there is the ninth; thus,

When used in a composition of four parts, and marked by a single 9, it has the accompaniment

of a third and fifth; thus,

Frequently, however, it is accompanied by a fourth and fifth, and then is marked with a

double row of figures; thus,

When the composition is in only three parts, the fifth is not used. With the third and fifth as an accompaniment, the ninth becomes then an appoggiatura, continued in the place of the eighth. The ninth has two inversions: one of them figured with a seventh on the third of the fundamental note; the other figured with a fifth and a sixth on the fifth of the fundamental note.

When any figures are dashed through, thus, $\frac{5}{3}$, it indicates that the intervals are to be sharpened.

Before leaving this part of the subject, we subjoin, as properly belonging to it, what is called the *harmony of the scale*; that is, the accompaniment which it carries in ascending and descending:—

MUSIC

Composition is the art of joining and combining concords and discords in such a manner that their succession and progression may be agreeable to the ear. It may be here mentioned that melody being chiefly the business of the imagination, its rules serve only to prescribe limits to it. But harmony is the work of the judgment; and its rules are more certain and extensive, and more difficult in practice. A person, indeed, unskilled in music may by chance make a piece of good harmony; but a person of judgment does it with certainty. In harmony, the invention has not so much to do; for the composition is conducted from a nice observation of its rules, assisted also by the imagination. It is not to be expected that in the compass of this article space can be afforded for a complete treatise on this part of the subject; all that we propose is to present to the reader some of the leading rules of the science.

The different motions of the parts which constitute harmony may be *direct* or *contrary*. In the former the parts move the same way, ascending or descending. In direct motion, the parts move the same way, ascending or descending,

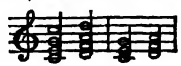

one of the parts rises whilst the other falls,

The latter is preferable.

As regards the motions and successions of concords: First, octaves and fifths must not be consecutive in direct motion. This for instance

is very bad, , and it may be avoided by giving the passages contrary

motion; thus, . Second,

unnecessary and distant skips must be avoided as much as possible, and the chords should be kept as close and as much connected as may be. Third, false relations, such as the extreme sharp second, must be avoided, unless the same be required for the purpose of expressing some

particular effect. Fourth, the regular motion of the different parts in harmony must be observed: sharp intervals should ascend after the sharp, whilst minor or flat intervals must descend after the flat. In observing this rule, however, that of avoiding consecutive octaves and fifths must nevertheless be observed; and it may also be neglected where certain effects are required. It is customary for a composition to begin with one of the concords of its key note, and it should end in the key note with its common chord for the harmony. To these we may add, that you must not go from an imperfect concord to a perfect octave or fifth by similar motion; such passages being said to contain *hidden* octaves or fifths, which will be seen by filling up the diatonic degrees through which one of the parts is conceived to pass.

We proceed to give a few remarks on the harmonic use of the intervals; but for the more complete development of the laws of harmony, special treatises on the subject must be referred to.

In the *second*, the lowest note is the discord. It may be prepared in any concord, and must descend to the resolution,

The preparation of a discord is effected by taking care that the note which is the discord is heard in the preceding harmony, its resolution being its descent either a tone or a semitone, according to the mode, after it has been struck. Those seconds are called *transient* which are introduced without preparation on the unaccented

part of the bar, thus, ; and if

these transient seconds be removed to the accented part of the bar, they then become appoggiaturas. When the second is attended by the fifth and third, it becomes a chord of four real parts, and retards the chord of $\frac{4}{3}$ or the $\frac{5}{4}$; and if the third be sharp, the minor mode is indicated.

A chord is said to have four real parts when it contains four sounds without octaves or unisons: a concord can only have three real parts. When the second is attended by the fourth and fifth, either the fifth or the fourth must be prepared; and it becomes the chord of the fifth and sixth at the resolution of the second by the bass.

MUSIC

The second accompanied with the sixth and fourth is a chord of four real parts, three of them forming a common chord above the bass, which being the discord must be resolved by a descent to the next degree: the sharp fourth usually

ascends,

The second is also

accompanied with the fourth and sharp seventh, which, when introduced upon a resting bass, allow all the intervals when struck to ascend,

When, however, the bass

moves, it is usual to prepare the upper parts,

The third major or minor, , is an agreeable concord; of which it is to be noted that two minor thirds in succession are better than two majors, but mixed thirds in succession are most pleasant to the ear; indeed, an octave of major thirds is extremely unpleasant. The third is sometimes accompanied by a fourth and sixth, . That species of it in which the third is minor, the fourth perfect, and the sixth major, is as elegant in effect as the seventh, from which it is derived. The following is an example:

Accompanied by the fifth, the fourth is a discord much used. When introduced on a resting bass, it resolves into the third; and its effect is so similar to that of the ninth, that they are frequently introduced alternately.

The chord of the fourth accompanied by the sixth is of great use in harmonical progres-

sions; and when preceded by the common chords to the key note and fourth of the key, and succeeded by the common chords to the fifth of the key and the key note, it forms one of the terminations to a musical period called the fourth and sixth cadence; thus,

When the seventh accompanies the fourth, and the latter is followed by the chord of the third, fifth, and seventh, either the fourth or seventh, or both, should be in some part of the chord preceding it. In the following example both the fourth and seventh are prepared and resolved:

The fourth

and seventh descend to the resolution, and generally resolve after each other.

The interval of the sharp fourth, which has been before mentioned, is a minor semitone more than the perfect fourth, and a major semitone less than the perfect fifth. Its natural resolution is that the bass shall fall a degree, and the upper part rise one, by which the two parts meet in a minor sixth. It is of very great use in modulation, as you can, by introducing it upon the key note, always change the mode you are in, as in the following

examples:

In

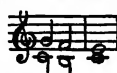

four parts the sixth and second are taken with it.

The interval of the imperfect fifth is a minor semitone less than the perfect fifth. In using this chord the highest note falls and the lowest one rises, so that they meet in a major

third; thus, . In four parts it is

accompanied by a third and sixth, .

The fifth is the next interval which we have to consider; of this we have already said that two perfect fifths cannot follow each other, except by contrary motion. A false fifth may

succeed a perfect fifth,  When

any note moves to a fifth in similar motion, there is said to be a *hidden fifth* in the

MUSIC

passage. The reader will, in the following example, see by the dots where these lie.

In a regular ascent, it is common for a fifth to be succeeded by a sixth, as in a descent it is common for the seventh to be succeeded by a sixth. Of both these, which are termed *sequences*, the following are examples:—

The extreme sharp fifth, which consists of two major thirds placed above each other, is generally considered and treated as a passing note, as in the following examples:—

It is here seen that the extreme sharp fifth to the bass, whether it be in the middle or at the top of the chord, always rises to the resolution. It is called a *transient chord*.

The sixth, by inversion, becomes a third; and it often happens that the bass which accompanies sixths will harmonise equally well with thirds. When accompanied with the fifth, the fifth is treated as a discord; this may be illustrated by two or three instances.

A species of this chord much used in minor keys consists of a perfect fifth, an extreme sharp sixth, and major third; and the

bass of it generally descends,

The major seventh accompanied with a third major and perfect fifth is one of the most agreeable of the discords; the seventh

should be prepared in the preceding chord

, and should be resolved

by descending. If the major seventh is, however, accompanied by the second and fourth, it resolves upwards on the octave. By raising the lower note of a minor seventh a minor semitone, the chord of the diminished or extreme flat seventh is produced.

This is also called the

Minor 7th. Diminished 7th.

equivocal chord, from the uncertainty of the key into which it may lead.

The ninth major is a whole tone, and the minor ninth a semitone major above the octave. Both should be prepared in the preceding chord, and resolved by descent. When the ninth is used in four parts, the third and fifth must be taken with it. It must be accompanied at the resolution by an eighth, if the piece be in four parts. We subjoin a few examples:—

The ninth may have other discords mixed with it, as the fourth, in which case the fourth must be prepared and resolved as a discord. The seventh may be also mixed with it; in which case the seventh must be also separately prepared and resolved.

Modulation consists, as we have before stated, in passing from one key to another. The methods of accomplishing this are almost numberless, and we can therefore only refer to the explanations given in books of harmony, or, still better, to the examples to be found in the works of all eminent composers.

Counterpoint refers to the composition of music in several distinct and separate parts. We have before said that harmony implies that several sounds are heard at the same time; and the art of counterpoint consists in so arranging these several sounds that each of them may belong to a distinct part, capable of being performed throughout by a separate voice or instrument. Each of these parts must form a kind of melody of itself, and yet when heard together the combination of them all must be

MUSIC

so arranged as to produce satisfactory harmony. It is in vocal compositions that counterpoint is chiefly exhibited—glees, madrigals, and choruses being all examples of this kind of music; but it is also shown in instrumental compositions, particularly for the stringed band, as in quartets and quintets, and also to some extent in orchestral works, although in these all the parts are not *real*, i.e. not perfectly distinct from each other. The best organ compositions, as for example the works of Sebastian Bach, are all strictly contrapuntal, and may indeed generally be divided into perfectly distinct parts, though played on one instrument only. In pianoforte music, the counterpoint is less decided; but a good composer will, whatever be the kind of music, always exhibit his contrapuntal power.

The number of distinct parts used in counterpoint of course varies exceedingly. It cannot exist with less than two; but this number must necessarily give imperfect harmony. Three is a better number, but four parts is by far the most common, and indeed the most satisfactory, as this number enables the harmony to be made quite complete, while, by a skilful arrangement, the parts, not being numerous, will make themselves each perfectly distinct to the ear. Beyond this the difficulty of composition increases; but five, six, seven, and eight parts are quite common in the church compositions and in the madrigals of the older composers. Indeed, so skilful were the ancient writers in this art, that compositions of twelve, sixteen, twenty-four, forty-eight, and even as many as ninety-six real parts are in existence.

The style of counterpoint may also vary considerably, and five kinds are generally mentioned in books on the subject; namely, 1. Note against note. 2. Two notes in one part to each one in another. 3. Three or four notes to one. 4. Syncopations in one of the parts; and 5. Florid counterpoint. There are rules for writing in all these styles, and in various numbers of parts, for which, however, we must refer to the many excellent treatises on the subject.

The study and practice of counterpoint have been greatly neglected by composers and students of the present day—a circumstance much to be regretted, as the successful application of the art gives to music one of its greatest charms.

There are several special forms of contrapuntal musical composition, as canon, fugue, and imitation.

A *canon* is a composition in which several parts take up strictly the same subject or theme, but at different points of time, and usually on different parts of the scale. Sometimes in some of the parts the subject is inverted, or taken backwards, or augmented, or diminished. The well-known grace after meat, *Non nobis Domine*, is a fine specimen of a canon in three parts.

A *fugue* is something like a canon, inasmuch

MUSICAL GLASSES

as the several parts repeat the same subject, but it is usually longer and less strict in style. Handel's choruses abound in fine fugues.

Imitation is even less strict. It is when the different parts merely imitate each other, without adhering strictly to the subject given. It is found in all sorts of music by good writers.

Rhythm is to music exactly what prosody is to poetry; namely, it relates to the division of the composition into parts of various lengths, so as to satisfy a natural desire for uniform motion and equable division of time. Thus the length and accentuation of each separate bar constitute a part of the rhythm of the whole piece; but in addition to this there are divisions of greater length, such as phrases, sections, and periods of two, four, or eight bars, which are necessary to give symmetry and perspicuity to the whole. Contrapuntal music, from its peculiar nature, is often without any rhythm, except the simple bar; but almost all music of a lighter or more modern kind is rhythmical; indeed, it must be so to be pleasing. The most perfect rhythm is found in dance music, in which the divisions into four and eight bars are very clear and intelligible.

Music Types. In Printing, the movable types used in producing cheap music in large quantities. The first really good music types were those cut by Mr. Hughes some five-and-twenty years since. Mr. E. Cowper invented a mode by which music could be printed in two forms, one being the lines, printed first, the other the notes, &c., printed upon it. This plan did not work well; and the late Mr. Branstons devised a method of striking the punches deeper into the plate, and then taking a stereotype plate from it in type metal. After the white parts were blocked out, the music was sufficiently in relief to be capable of being printed at the common printing press. MS. music types, however, cast in good metal, best answer the purposes of the printer.

Musical Glasses. A musical instrument consisting of a number of glass goblets, resembling finger glasses, which are tuned by filling them more or less with water, and played upon with the end of a finger damped. There are few persons at a dinner table who have not tried their skill in producing the sound which the vibration of a finger glass will yield in the way above described. The less the quantity of water in glasses of similar forms and equal capacity, the lower will be the tone of the scale; hence the facility of forming a complete scale by the quantity of water contained in each.

The skill, or rather knack, of operating upon the sets of glasses for the production of melodies and harmonies, is that of procuring instantly the required vibration by a gentle and rapid action of the finger upon their edges, and so quickly from one to another as to be able to introduce harmonies to the sounds of the air or melody before the vibrations of its glasses have ceased. A touch of the finger on

MUSK

the edge of a glass puts, of course, a stop to its vibration, and thus prevents confusion.

Musk. A peculiar concrete substance, the produce of the *Moschus moschiferus*, or musk deer, an animal which inhabits the mountains of Eastern Asia. Behind the navel is a bag, which in the adult animal is filled with musk. These bags are imported from China, Bengal, and Russia. Musk is originally a viscid fluid, but dries into a brown pulverulent substance, of a strong, peculiar, and highly diffusible odour. Its chief use is as a perfume: it has been employed in medicine as a stimulant antispasmodic, but much difference of opinion exists as to its efficacy; and its high price and extreme liability to adulteration are against its use.

MUSK, ARTIFICIAL. A substance obtained by the action of nitric acid upon oil of amber, and having an odour which some have thought to resemble that of musk.

Musk Deer. *Moschus moschiferus* (Linn.). The type of a distinct genus of Ruminants, with canine teeth and without horns. This species is especially remarkable for the large preputial glandular pouch which secretes the well-known substance called *musk*.

Musk Root. The Sambul root, supposed to be derived from a species of *Angelica*; also the Spikenard, *Nardostachys Jatamansi*.

Muskat. A rich sweet wine, made, in the South of France, of over-ripe muscadine grapes.

Musket. The firearm used by the regiments of the line. A great number of very curious muskets, of various dates and countries, from the earliest period of their use, may be seen in the repository of the Royal Artillery at Woolwich. 'When hawks were supplanted by firearms, the name of the birds of prey, formerly used in hawking, were transferred to the new weapons. *Mosquet*, the name of a sparrow-hawk, so called on account of its dappled (muscat) plumage, became the name of the French *mousquet*, a musket. *Faucon*, hawk, was the name given to a heavier sort of artillery. *Saors* in French and *saker* in English mean both hawk and gun; and the Italian *tersemolo*, a small pistol, is closely connected with *terzuolo*, a hawk. The English expression, *to let fly at a thing*, suggests a similar explanation.' (Max Müller, *Lectures on Language*, second series, p. 229.) Mr. Wedgwood (*Dict. of English Etymology*, s.v. 'Musket') holds that *mosquet*, as the name of a hawk, was not taken from its speckled breast, but is to be identified with the Dutch *mossche*, *mussche*, a sparrow, a word preserved in the English *titmouse*. It appears, further, that the words, *mosquette* and *muschita* signified an arrow long before the invention of firearms. The archives of Bologna for 1381 contain an item, 'Ducas septuaginta quatuor muschitas impennatas de carta in unâ cistâ,' and similar items occur in the archives of Lille for 1382. (Napoleon III. *Études sur l'Artillerie* i. 361.) This, however, only throws the metaphor one stage further back, the name of the hawk having been used to de-

MUSTARD

note first an arrow and then a firearm. [SMALL-ARMS.]

Musketeer (Fr. *mousqueton*). A species of musket in use towards the close of the seventeenth century, shorter, but thicker and wider in the bore, than the ordinary musket. It had a flint lock.

Muslin. A fine thin kind of cotton cloth with a downy nap on the surface. The name is derived from the town of Mosul, in Asia, where it was originally manufactured. The first muslin was imported from India into England in 1670; and twenty years afterwards it was manufactured in considerable quantities both in France and England. Muslins are now manufactured in immense quantities at Manchester and Glasgow, in France, Germany, and Switzerland, rivaling those of India in fineness and durability, while they are also much cheaper. [COTTON.]

Musophaga. A genus of Scansorial birds, characterised by the base of the beak forming a disc which partly covers the forehead. The species of this genus are called *plantain eaters*, because their principal food is the fruit of the banana.

Mussel. [MYTILUS.]

Mussite. A greyish-green variety of Diopside, from the Mussa Alps in Piedmont.

Musulman. A general appellation in European languages for all who embrace the faith of Mohammed. The term is derived from the Arabic *muslim*, a believer, and is said to have been first applied in Europe to the Saracens.

Must (Lat. *mustum*, Ger. *most*). The expressed juice of the grape before its conversion into wine by the process of fermentation. According to Berard the juice of ripe grapes contains sugar, gum, gluten, malic acid and malate of lime, bitartrate of potash and bitartrate of lime. The acidity of the juice of ripe grapes is principally due to the tartar which it contains, and which is precipitated by the alcohol formed during fermentation.

Mustard (Fr. *moutarde*, Venetian *mostarda*). The common name for *Sinapis*. The white mustard is *Sinapis alba*, and the black mustard *Sinapis nigra*. The seeds of the former are grown with those of cress to furnish what is known as small-salading; and together with those of the latter they furnish, when ground, the mustard of commerce. The mustard-tree of the New Testament is by some persons regarded as being the *S. nigra*, which in the climate of Palestine grows to a much larger size than with us; but by others it is considered to be a species of *Salvadora*.

The seed of the *Sinapis alba* and *nigra* forms, as already mentioned, when ground into powder and freed from the husks, the well-known condiment of the shops, or at least a part of it; for in order to reduce the strength of the pure mustard, a considerable quantity of wheaten flour is generally added. Brown mustard should be the flour of *Sinapis nigra* exclusively, which

MUSTARD

is much more pungent than the other. A dessert-spoonful of coarsely powdered mustard seed, taken in a glass of water, generally operates as an emetic; it is also aperient. A mustard poultice, or *sinapiem*, is sometimes a useful stimulant.

Mustard, Oil of. Mustard contains a fixed oil composed of erucin and olein, and also yields, when moistened with water, a volatile oil which is the sulphocyanide of allyl. The latter is the source of the pungent flavour and odour characteristic of recently made mustard paste. It is produced by the action of a ferment, *myrosin*, upon *myronic acid*, in the presence of water, and does not therefore pre-exist in the mustard seed, but is first formed when the crushed seed is macerated with water.

Mustela (Lat. *a weasel*). The generic name under which Linnaeus comprehended the Vermine or Vermiform quadrupeds of Ray, or the carnivorous Mammalia, which are distinguished by the length and slenderness of their bodies, and are thus enabled to wind, like worms, into very small crevices and openings, whither they easily follow the little animals that serve them for food. The otters, skunks, polecats, and weasels were included in this genus, and still constitute the natural family *Mustelidae*; but the genus *Mustela* is now restricted to the true weasels, which differ from the polecats in having an additional false molar above and below, and in the existence of a small internal tubercle on the lower carnassial or sectorial tooth; two characters which, Cuvier observes, somewhat diminish the cruelty of their nature.

Musters. On Shipboard, a weekly calling over of the men, each of whom passes across the quarter-deck as his name is called. It takes place also after a battle in order to ascertain the casualties.

Musters-roll (Old Fr. *monstrer*, to show or review). A specific list of the officers and men in every troop, battery, or company, accounting for every individual. At *muster*, which takes place on the last day of every month, every name on this list is called, and any officer absent without leave is not entitled to pay for the following month. A soldier so absent is not entitled to pay for that day, and is liable to imprisonment.

Mute (Lat. *mutus*). A dumb officer of the seraglio, whose duty it is to act as executioner of persons of exalted rank who have incurred the sultan's displeasure. The term *mute* is also applied to persons employed by undertakers to stand before the door of a house in which there is a corpse, for a short time before the funeral.

MUTE. In Grammar, a vowel (or consonant) is said to be mute when written but not pronounced; as the vowel *e* at the end of many English words, in some of which it effects a change in the pronunciation of the preceding vowel, as in *wife*, *life*, *place*, &c., rendering it long; after a diphthong it has no effect, as in

MUZZLE

house. In old English, the *e* now mute in many words, especially in nouns, retained its inflexional character and had a syllabic power, as in the poetry of Chaucer, &c.

MUTE. In Law, this term is applied to a person who refuses to plead to an indictment for felony, &c. By stat. 12 Geo. III. c. 20 such a person is to be considered as pleading guilty, but by 7 & 8 Geo. IV. c. 28 the court may order a plea of *not guilty* to be entered for him: Formerly a plea was extorted from him by the inhuman process of *PEIN FORTE ET DURE* [which see].

Muticus (Lat. *muticus*, *maimed*). A name applied by Linnaeus to the third of his primary divisions of Mammalia, including the whale tribe, as being maimed, or deprived of the hinder pair of extremities; also given by Storr to an order of quadrupeds comprehending those which want either a certain kind of teeth, or are wholly edentulous.

Mutilata (Lat. *mutilata*). This division of Gyrencephalate Mammalia is so called because their hind limbs seem, as it were, to have been amputated: they possess only the pectoral pair of limbs, and these in the form of fins; the hind end of the trunk expands into a broad horizontally flattened caudal fin. They have large brains with many and deep convolutions, are naked, and have neither neck, scrotum, nor external ears. It is composed of the two orders *Cetacea* and *Sirenia*.

Mutiny (Fr. *mutin*, *rebellious*). In Law, the offence, in a person under military or naval authority, of resisting or refusing obedience to that authority. The Mutiny Act is a statute annually passed since the reign of William and Mary (April 1689), by which the crown is vested with power to form articles of war, and to constitute military courts martial. [COURTS MARTIAL.]

Mutule. [MODILLION.]

Musarabes, Mosarabes or Mostarabes. Christians living under the government of the Moors in Spain; so called, it is said, from an Arabic word signifying adoptive Arabs (*adscititii*). The denomination is now chiefly remembered in consequence of the celebrated disputes between the supporters of the Musarabic liturgy, which was preserved by the Christians of Spain during their subjection to the Mohammedans, and those of the Roman, introduced by the see of Rome about the tenth century. During the following age this dispute was warmly carried on, and well-known legendary tales of miracles wrought in favour of the ancient ritual were long current in Spain. It was, however, gradually superseded by the Catholic. It is said that mass is still celebrated according to the Musarabic ritual in one chapel at Toledo. (Gibbon, *Roman Empire*, ch. li.)

Muzzle (Fr. *museau*, Ital. *muso*). In Artillery, the part of a gun next the mouth. [GUN.] In the smooth-bored cast guns, the thickness of metal is increased at the muzzle, forming what is called the *twip* or swell of the muzzle.

M. The lashing by which the muzzle of a gun in a ship is secured to the upper part of the port, to prevent motion during rough weather.

Mya. A name applied by Linnæus to a genus of the *Formes Testaceæ*, including those having a bivalve shell, characterised by a hinge with broad, thick, and strong teeth, seldom more than one, and not inserted into the opposite valve; shell generally gaping at one end. The Molluscs thus characterised form the first family (*Myacidae*) of the section *Siphonida* among the conchiferous Mollusca. They have been subdivided into the genera *Mya*, *Corbula*, *Sphenia*, *Neora*, *Thetis*, *Saxicava*, *Glycymeris*, *Panopæa*.

Mycoelia (Gr. *μύκης*, a fungus). The young flocculent filaments of fungi.

Mydriasis. Preternatural dilatation of the pupil of the eye.

Myelencephalus (Gr. *μυελός*, marrow, and *ἐγκέφαλος*, brain). The name indicative of the condition of the nervous system of the primary division of animals, comprehending those which have a brain and spinal chord: it is synonymous with *Vertebrata*.

Myelina. A yellowish or reddish variety of Kaolin from Rochlitz in Saxony.

Myelon (Gr. *μυελός*, marrow). The single-worded equivalent of *spinal marrow* and *spinal cord*.

Myeloneura (Gr. *μυελός*, and *νεῦρον*, nerve). A name given by Rudolphi to a group of animals corresponding to the *Articulata* of Cuvier, viz. Crustacea, Insecta, and Anellides, which have a gangliated nervous system, forming a chord considered to be analogous to the spinal marrow of Vertebrates.

Mykomelinic Acid. An acid resulting from the mutual action of allozan and ammonia. [URIXA.]

Mylo. Names compounded of this word are applied to certain muscles attached near the grinder teeth, as *mylohyoidæus*, *mylopharyngeus*, &c. [MOLARS.]

Myliodon (Gr. *μυλίδων*, a grinder tooth). A genus of *Megatheriidae*, which was discovered by Mr. Charles Darwin, at Punta Alta, near Bahia Blanca, in Northern Patagonia. The entire skeleton, which is now in the College of Surgeons, affords a proof of the existence of an animal not so large nor so powerfully built as the gigantic *Megatherium*, but teleologically adapted like that species for the uprootal, by energetic vibration, of the trees on the tender succulent leaves of which it depended for sustenance.

Myocommata (Gr. *μυελός*, and *κόμμα*, a section). The lateral flakes into which the muscular system of fishes is divided. Each is attached by its inner borders to the osseous and sponenrotic parts of the corresponding vertically extended segment of the endoskeleton, by its outer borders to the skin, and by its fore and hind surfaces to an sponenrotic septum, common to it and the contiguous myocommata.

Myology (Gr. *μῦον*, a muscle, and *λόγος*). The doctrine of the muscles. In the Fine Arts, the term is applied to a description of the muscles of animals.

Myoporaceæ (*Myoporum*, one of the genera). One of the orders of perigenous Exogens included in the Ecbial alliance, and distinguished by the irregular unsymmetrical flowers, confluent nuts, pendulous ovules, and two-called anthers. The *Avicennias* which belong to this group are shore trees, living like Mangroves in salt swamps.

Myops (Gr. *μῦψ*, blinking). A person who is purblind or near-sighted. This defect usually arises from too great convexity of the cornea causing the rays to come to a focus before they arrive at the retina. It is corrected by the use of glasses which increase the divergence of the rays before they enter the cornea, and thereby throw their focus farther back, so as to fall on the retina.

Myriad (Gr. *μυριάς*). Ten thousand. The word is often used as expressive of an indefinite multitude.

Myrialitre. A French measure of capacity equal to ten thousand litres, or 610,280 cubic inches.

Myriamètre. A French measure equal to ten thousand mètres; it is the equivalent of two leagues of the old measure. [MEASURES.]

Myriapods (Gr. *μυριάς*, myriad, and *ποῦς*, foot). The name of a class of Articulate animals, including those which have an indeterminate number of jointed feet, equalling that of the articulations of the body.

Myrica (Lat.; Gr. *μύρτις*). The typical genus of the *Myricaceæ*, consisting of small shrubs or small trees, one of which, *M. Gale*, is a native of bogs in this country, and is called Sweet Gale or Bog Myrtle on account of its fragrant leaves. The pleasant acid fruit of *M. sapida*, which is about as large as a cherry, is eaten in Nepal. The most important, however, is the wax-bearing *M. corifera*, the fruits of which are coated over with a thickish waxy secretion.

Myricaceæ (*Myrica*, one of the genera). A small order of diclinous Exogens of the Amental alliance, distinguished by their one-celled ovary and single erect seed with a superior radicle. The order comprises only *Myrica* and one or two other small genera.

Myricin. That portion of wax which is insoluble in alcohol. It melts at 147° Fahr. The wax of the *Myrica corifera* affords it.

Myricylic Alcohol. The hydrated oxide of myricyl. The oxide of myricyl exists in bees-wax in combination with palmitic acid, and is liberated in the hydrated form by the action of caustic potash. Myricylic alcohol is a colourless solid, of a silky lustre, melting at 185° Fahr.

Myriorama (Gr. *μυριάς*, a myriad, and *ῥάμα*, I view). A picture made up of fragments of buildings, landscapes, &c., so as to admit of an infinity of combinations.

MYRISTIC ACID

Myristic Acid (Gr. *μύρος*, *unguent*). One of the fatty acids contained in the expressed oil of nutmeg.

Myristica (Gr. *μυριστικός*, *fit for anointing*). The genus of *Myristicaceae* which yields the Nutmeg. This fruit is the produce of *M. moschata*, or *officinalis*, a tree of the Molucca Isles, Java, &c. growing twenty feet or more in height, bearing elliptic leaves, and axillary clusters of flowers. The fruit, which resembles a peach, bursts into two pieces, by which the enclosed seed covered by its arillose or false aril (Mace) is exposed. The seed has a hard outer shell, which is removed when dry, the albuminous interior mass forming the Nutmeg of the shops. The most esteemed are those of Penang. *M. fatua*, *Otoba*, *tomentosa*, *acuminata*, and others, especially the first, yield nutmegs which find their way into the market from Brazil, the Philippine Islands, and Madagascar.

Myristicaceae (Myristica, one of the genera). A natural order of arboreous Exogens inhabiting the tropics and belonging to the Menispermal alliance of didymous Exogens, in which they are known by their valvate cup-shaped calyx, and their ruminated albumen.

It has been sometimes placed in *Lauraceae*, from which it is distinguished by the structure of the calyx, anthers, and fruit. Brown places it between *Proteaceae* and *Lauraceae*; and it has also been regarded as an apetalous form of *Anonaceae*, agreeing in the trimerous flowers, arillate seed, ruminated albumen and minute embryo. The bark generally abounds in an acrid juice, which is viscid and stains red. The rind of the fruit is caustic; the aril and albumen of *Myristica moschata*, the former known under the name of *Mace* and the latter of *Nutmeg*, are important aromatics abounding in a fixed oil of a consistence analogous to fat, which, in a species called *Pirola sebifera*, is so copious as to be extracted easily by immersing the seeds in hot water.

Myristin. Myristate of glyceryl, from nutmeg-butter.

Myrmecobius (Gr. *μύρμηξ*, *ant*; *bios*, *life*). A genus of Marsupial quadrupeds which feed

The only known species, *Myrmecobius fasciatus*, is a native of Australia.

Myrmecophaga (Gr. *μύρμηξ*, and *φάγω*, *I eat*). The name of a genus of Edentate quadrupeds which feed on ants, and are called *ant-eaters*. They are peculiar to the continent of South America.

Myrmecoleonides (Gr. *μύρμηξ*, and *λέων*, *lion*). The family of insects commonly called *ant-lions*, having the genus *Myrmecoleon* as the type.

Myrmidons (Gr. *Μυρμιδόνες*). The followers whom Achilles led from Phthia to the Trojan war. The name (like that of Achilles, Helen, Paris, and many others) cannot be explained by any Greek words. According to one version of the myth, Zeus deceived Eurymedusa, daughter of Cleitus, in

ΜΥΛΙΝΑΟΡΕΑ

the form of an ant (*μύρμηξ*), and became the father of Myrmidon, the eponym of the Myrmidones. The Homeric poems exhibit the Myrmidons as warriors who cannot set except at the bidding of Achilles. Where he appears, they rush forth like wolves, *λύκοι* *ἔσσι* (*Il. xvi. 166*). The simile which follows lays special stress on the fiery colour of their cheeks, and the blood-red hue of their tongues and jaws. These images are in strict accordance with the solar character of Achilles [*MYTHOLOGY*], and the expression *λύκοι* thus at once suggests a comparison with the myths of LYCAON, Callisto and Arcas, and with the epithet Lycius (*Λύκιος*) applied to Phœbus (*Æschylus, Theb. 145*). The Myrmidons would thus be the streaming rays which break forth when the sun reappears after being veiled by clouds. [*EPIC; ILLAD.*]

Myrobalan (Gr. *μυροβόλας*, because formerly used in the preparation of unguents). A bitterish austere fruit, brought from India. Belleric Myrobalans are the fruit of *Terminalia Bellerica*, Chebulic of *T. Chebula*, Indian of *T. citrina*. Myrobalans are used by the Hindus in calico printing and medicine. The fruits of *Emblia officinalis* are sometimes called Emblic Myrobalans.

Myronic Acid. One of the components of black mustard seed.

Myrosin. [*MUSTARD, OIL OF.*]

Myrospermum (Gr. *μύρος*, and *σπέρμα*, *seed*). To this genus of *Leguminosae* belong the plants yielding the Balsams of Peru and of Tolu. The first is the produce of *M. peruvianum*, and is obtained by making incisions in the bark, thrusting cotton rags into the wound, and lighting a fire round the tree to liquefy the balsam. The rags are afterwards boiled, and the balsam collects below. It has a fragrant aromatic smell and taste, and has been used in chronic coughs, &c. The second is similar in character, and is derived from *M. toluiferum*. They are tropical American trees, with unequally pinnate leaves, and axillary racemes of white or rose-coloured flowers.

Myroxyllic Acid (Gr. *μύρος*, and *ξύλον*, *sharp*). A substance obtained from the Peruvian balsam, the produce of the *Myrospermum peruvianum*, formerly called *Myroxylon*.

Myrrh (Lat. *myrrha*, Gr. *μύρρη*). This gum resin is imported from Turkey. It is produced by *Balsamodendron Myrrha* in irregular tears and lumps, of a reddish brown colour, a fragrant odour, and a warm but bitter taste. It is a good stimulating tonic medicine, and is given in doses of from five to twenty grains.

Myrrhic Acid. A substance obtained by heating the resin of myrrh.

Myrsinaceae (Myrsine, one of the genera). A natural order of perigynous Exogens, referred by Lindley to his *Cortusial* alliance. In this group they are known by their woody stems, by having stamens opposite the petals, and by their indehiscent drupeaceous fruit.

MYRTACEÆ

They occur chiefly in islands of equable temperature, as those of the Indian Ocean, Mauritius, Bourbon, and Madagascar. Many of them are ornamental, but little is known of their properties. Bread is said to be made from the pounded seeds of *Thocophrasta Jussiei* in St. Domingo.

Myrtaceæ (*Myrtus*, one of the genera). An important natural order of polypetalous Exogenous plants of a woody texture, frequently forming small trees, and found in all tropical and temperate countries, where they are often cultivated for the sake of their valuable aromatic properties. They belong to the Myrtal alliance of epigynous Exogens; and their most essential characters are to have polypetalous calycifloral flowers, indefinite stamens, round erect anthers, inferior fruit, and dotted leaves with an intra-marginal vein. The spices *Cloves* and *Pimento* are produced by *Caryophyllus aromaticus* and *Eugenia Pimenta*; the agreeable fruits called *Guava*, *Jamrosade*, and *Roseapples* are yielded by *Psidium Guava*, *Eugenia malaccensis*, &c.; while the enormous *Gum-trees*, or *Eucalypti*, of New Holland, and the *Melaleuca*, which furnishes the oil of *cajeput*, also belong to the order. *Myrtaceæ* are nearly related to the Onagraceous order, from which they differ in having an indefinite number of stamens; and to *Melastomaceæ*, which have rostrate inflected anthers and ribbed leaves.

Myrtle. [*Myrtus*.]

Myrtus (Lat.; Gr. *μύρτος*). The typical genus of the order *Myrtaceæ*, and best known by the Common Myrtle, *M. communis*, a shrub with fragrant shining evergreen leaves and white flowers. Amongst the ancients the Myrtle was held sacred to Venus. The wood is very hard, and beautifully mottled.

Myacrine. An anhydrous carbonate of copper found at Mysore in India.

Myrtacineæ (Gr. *μύρα*, the upper lip or moustache). The name of a family of Infusories of the tribe *Trichoda*, including those which

have cilia, or fine hair-like processes,

Many species of animals derive their trivial name from the same root, as the *Vespertilio mystacinus*, or whiskered bat; the *Caprimulgus mystacinus*, or bearded goat-sucker; the *Cypselus mystaceus*, or bearded swift, &c.

Mysterics (Gr. *μυσ*, to be closed or shut, hence *μυσ*, to initiate in mysteries, *μύστος*, one so initiated, and *μυστήριον*). The desire to shroud certain doctrines or ceremonies in an obscurity penetrable only by those who have undergone a systematic initiation seems to have been common to most ancient nations. Thus, we find such mysteries or orgies existing in Egypt, Asia Minor, Greece, &c.; and it has been thought that in the latter they were directly derived from the former. But if there is little doubt that the Greek mysteries were greatly modified by the influence of Egyptian sacerdotalism, the existence of mysteries in Greece before any such influence could have

MYSTERIES

been exercised seems scarcely less clear. Beyond this, the subject is involved in great uncertainty, and it might be rash to do more than state the opinions, sometimes conflicting, which have been entertained by historical critics with regard to the origin and character of these mysteries. The idea that from beginning to end they were an imposition for the mere purpose of extending the authority of priests, may perhaps be dismissed at once. As in the case of the oracles, the mysteries could never with such a foundation have held their ground, while it is also certain that the initiated were not only not all priests, but numbered among their ranks some of the wisest thinkers and the greatest statesmen. In Greece, and especially at Eleusis, the rites had apparently a local significance, and were directly referred to distinctively Pelasgic gods; hence some historians have connected the mysteries with the primitive religion of Greece, before the introduction of the frenzied rites of Egypt, Asia Minor, and Thrace. Thus Bishop Thirlwall regards them as 'the remains of a worship which preceded the rise of the Hellenic mythology and its attendant rites, grounded on a view of nature, less fanciful, more earnest, and better fitted to awaken both philosophical thought and religious feeling.' At the same time he thinks it 'extremely doubtful how far they were ever used for the exposition of theological doctrines differing from the popular creed.' (*History of Greece*, ch. xii.) In the same way, from the manner in which they were all confused in the minds of various authors, Mr. Grote (*History of Greece*, part i. ch. i.) infers a close correspondence in character between the rites of the Idæan Zeus in Crete, of Dêmêtér at Eleusis, of the Cabeiri in Samothrace, and Dionysus (Bacchus) at Delphi and Thebes. These rites were in his opinion originally devoid of the element of mysticism or secrecy which, 'if not originally derived from Egypt, at least received from thence its greatest stimulus;' but he adds that this change altered also the original idea, and that the secrets which they now professed to teach would 'be such as to justify by their tenor the interdict on public divulgence,' and he concludes that it has never been shown, and is to the last degree improbable, 'that any recalcitrant doctrine, religious or philosophical, was attached to the mysteries, or contained in the holy stories,' whether of the Egyptian priests or any others. On the other hand, Dean Milman (*History of Christianity*, vol. i. ch. i.) attributes to them a Pantheistic doctrine, and a morality springing from the ancient Nature-worship of the East. But that the character of these mysteries was essentially dramatic, is beyond question. (Grote, *History of Greece*, part ii. ch. xliii. vol. v. 282, note.) This fact is clearly proved by the concluding ceremonies of the greater Eleusinian mysteries (apart from anything which may have preceded them), when the initiated, returning to Athens, sat down to rest on the roadside, and assailed all passers-

MYSTERIES

by on the bridge of the Cephissus with coarse ribaldry and ridicule. This jesting and scoffing, according to the local explanation, merely represented the rude playfulness of the servant-maid Iambé, who (in the Homeric hymn to Déméter) is said to have distracted the grief of the sorrowing goddess. (*Grote's History of Greece*, vol. i. p. 56 &c.)

Of the Egyptian mysteries, and the alleged marvels which they revealed to the initiated, little can be said with certainty. Probably 'their ceremonies were at once more licentious and more profane in the outpouring both of joy and sorrow than the Greek; and an intricate yet thoroughly organised priestly system brought the dramatic character of their mysteries to bear with greater power on the minds of the worshippers. The symbolical instruction, which is said to have been given in these mysteries, forms the groundwork of some chapters in Moore's *Tale of the Epicurean*. (For a further account of them, see *Cabinet Cyclopædia*, vol. lxi.; Sir G. Wilkinson's *Ancient Egyptians*, vol. ii. second series.)

It is, however, urged by some, that the opinions already noticed afford only a partial explanation of the phenomena of the mysteries; that religious celebrations accompanied by rites which are in varying measure common to Greece, Egypt, Syria, Phœnicia, Hindustan, and other countries, cannot be explained by reference to local customs, legends, or myths of any one of those countries; that no theory can be accepted as satisfactory which fails to throw light on the scattered and broken evidences which seem to indicate a common origin for all; that this common origin seems to be the worship of the vivifying principle, as exhibited in the procreative powers of living beings, and symbolised in the rites of Adonis, Aphrodite, Isis, Thammuz, Déméter, and other deities. That the *LINGA* from time immemorial has been a chief symbol of Hindu worship, is, it is maintained, as little to be questioned as that the adoration of the *PHALLUS* entered largely into that of the Greeks. The corresponding emblem to the *Linga* was the *Yoni*, or symbol of the earth, as the mother of living things; and this symbol, under its name *Argha*, signifying a cup or vessel, gave rise, it is affirmed, to the myth of the ship *Argo* (*signum in modum liburnæ figuratum*: Tacitus, *German.* 9), *Iswarra* (*Dionysus*) being styled *Argha-Nautha*, or lord of the boat-shaped vessel. The authority of Theodoret, Arnobius, and Clement of Alexandria is claimed for the assertion that the *Yoni* of the Hindus was an object of veneration in the Eleusinian mysteries; and it is asserted that the purification of women in these mysteries (as exhibited in vases in the Hamiltonian collection at the British Museum), answered closely to that of the Sacti in the mysteries of the Hindus.

The whole subject requires obviously the greatest caution, and the most rigorous scrutiny of facts and evidence; but as the enquiry is still in a very early stage, it would be premature

MYSTICISM

to add any further remarks to the foregoing sketch of the several opinions entertained by recent writers.

MYSTERIES. In Modern Literature, a species of dramatic composition, with characters and events drawn from sacred history. The mysteries of the middle ages are thought by some to have been first introduced by pilgrims returning from the Holy Land. They originated among, and were probably first performed by, ecclesiastics. However serious and solemn the events which were represented in these singular compositions, there were invariably, in the later mysteries, two characters introduced to make sport for the multitude: namely, the Devil and the Vice—a personage accoutred in a long jerkin, a cap with ass's ears, and a dagger of lath. He is now best remembered by the allusions to his character and office in the plays of Shakespeare. Miracles, or miracle-plays, were a species of mystery: they are usually said to have represented the martyrdoms of saints. In the sixteenth century, the mysteries were succeeded by *moralities*, which were much in vogue about the time when the Reformation made its chief progress in England. The characters in moralities were allegorical personages. Several of these performances, some by no means destitute of poetical merit, remain to us. They may be considered as the last step in the progress made by the dramatic art in modern Europe, before it reached the station and character which it has ever since retained.

The first biblical play on record is on Moses, and was the work of a Jew named Ezekiel in the second century; the second is a Greek tragedy on the Passion by Gregory Nazianzen. Religious plays were at an early time introduced into convents, and eagerly welcomed as breaking the monotony of convent life. A German abbess named Hroswitha composed some dramas of this kind in the tenth century. A great Passion-play is still celebrated every tenth year at the little village of Oberammergau in Bavaria; and such representations may be seen more frequently in the Basque country. (Lecky, *History of Rationalism*, vol. ii. ch. vi.; Francesque Michel, *Le Pays Basque*; *Edinburgh Review*, April 1864, p. 378 &c.)

MYSTICISM. In Religion, a word of very vague signification, applied, for the most part, indiscriminately to all those views or tendencies in religion which aspire towards a more direct communication between man and God (not through the medium of the senses, but through the inward perception of the mind) than that which may be obtained through revelation. Thus, the Pantheism of the ancient philosophers and many modern religionists, which supposed a God existing in all space and matter, and revealed to us in the outward manifestations of things; the Quietism of Madame Guyon, Fénelon, &c., who sought for direct revelation from the Divinity to the believer in a species of ecstasy; the Pietism of Molinos; the doctrines of the Illuminati in Germany; the visions of Swedenborg; and some of the notions

MYTHOLOGY

prevalent among the Methodists and other sects among ourselves—all approximate to mysticism.

Mythology (Gr. μυθολογία). By this term is generally understood the body of legends or traditions handed down by a people respecting their gods, heroes, and preternatural beings. It has been ascertained that the mythology of all the Aryan nations has a common source and groundwork: and that this groundwork was the ordinary speech of the people before the dispersion of the race. This language, as is evident from the Vedic Hymns, &c., attached a living force to all natural objects; and when its original meaning had been half forgotten by the several branches of the race in their new homes, its expressions still remained in the description of personal and anthropomorphous gods. Every word became an attribute, and all ideas, once grouped around a single object, branched off into distinct personifications. Thus the sun had been the lord of light, the driver of the chariot of the day; he had toiled and laboured for men, and sunk down to rest after hard battle in the evening. From such phrases sprang Phœbus and Apollo; and while Helios remained enthroned in the sun, his toils and death-struggles were transferred to Heracles (Hercules). Thus Endymion, a word meaning nothing more than the setting sun, became a youth who slept in the cave of Latmos (or forgetfulness). [LATHA and LATONA.] Hence the mythology of the Greeks, Romans, &c., becomes strictly a part of comparative philology, and can only be explained by it.

MYTHOLOGY, COMPARATIVE. As long as any people are acquainted only with their own legends and their own language, it is as impossible for them to analyse these tales to any good purpose as it was for Cæsar to know that the Gauls whom he subdued spoke a language akin to his own. The Greek could not of course fail to see the meaning of many names in his mythology. He could not but know that such names as Telephassa, Eurycleia, Eurygeneia, Iolê, Phaethon, were words which signified light, far-shooting and wide-spreading: but there were many others of which he could make nothing. He had received the exquisite legend of HERMES [which see]; but he had not the clue to guide him to the origin of the name: and he was wholly unable to explain such names as Achilles, Paris, Helen, Procris, Ixion, by any words belonging to his own language. Hence he was driven to conjecture; and each false guess became probably the germ of a new version of the myth, while it removed the tale farther from its original condition of mythical speech into the concrete form of an anthropomorphous and not unfrequently repulsive and immoral legend. Of these tales each country and almost every city retained its own version, without any consciousness that they were for the most part only different forms of the same story. Thus the citizen of Argos took pride in the myths

which clustered round the name of Perseus; while the men of Athens, Calydon, and Thebes had their tales of Theseus, Œdipus, and Meleagros. Yet the deeds attributed to them resembled each other in a way which nothing but the difference of names could have hidden from their eyes. Perseus is the destroyer, and he is the slayer of Medusa and the Libyan monster; but Apollo, also the destroyer, slays the serpent Python, and Bellerophon is the slayer of Belleros. Perseus goes to the land of the Graiæ and the Gorgons against his will; but against his will Heracles also toiled for Eurystheus, and Apollo served as a bond-man in the house of Admetus. Theseus also is a destroyer. He slays the Minotaur, and destroys the mighty robbers who desolated the land. Perseus again is the child of Danaë, and the golden shower; but Phœbus is born in Lykia, the land of light. [LYCAON.] All these heroes, again, move from east to west, Perseus to the home of the Gorgons, Heracles to the land of the Hesperides, Kephalos from Hymettus to the Leucadian cape. They are all armed with invincible weapons: Apollo Chysaor bears his sword; Artemis the spear which slays Procris; Bellerophon, Heracles, and Achilles the arrows which no enemy may withstand. All labour for the good of men, and the life of all closes in darkness, and generally with disaster. Perseus slays Acrisius, Œdipus kills Laios, Kephalos destroys Procris; and all do these deeds unwittingly. These parallelisms may be indefinitely extended. Œdipus, Paris, Perseus, Telephos, are all immediately after their birth cast forth to die: all are preserved in the same way with Cyrus, Romulus, and Chandragupta. If Theseus abandons Ariadne, Paris forsakes Œnonê, while Deianeira and Coronis are deserted by Heracles and Apollo. The imagery which runs through the legends is the same. A spotless white bull bears Europa across the sea: a golden ram carries away the children of Nephelê, the cloud. Hermes steals the herds of Phœbus, the lord of light; while Phaëthusa and Lampetis, the bright and glistering, lead the cattle of Helios, the sun, to their pastures. But while to the Greeks all these were different personages, their legends exhibit many points of contact: and thus the epos of Argos, for example, is twisted into a complicated chain with that of Attica. All this by itself is remarkable enough; but the wonder becomes much greater when we find stories substantially the same recurring in the mythology of Northern Europe. The Norse heroes are likewise destroyers of dragons that lie coiled round sleeping maidens, and Sifrit and Sigurd toil and fight for others not less than Heracles, Perseus, Achilles, or Bellerophon. If Heracles sees Iolê again at the end of his career, if Briseis is restored to Achilles, and Œnonê to Paris, so Brenhyldr comes before Sigurd in the hour of his death. Like Achilles, the Norse Baldr and the Persian Isfendiyyar can be wounded only in a single spot. The life of Meleagros

MYTHOLOGY

cannot be cut short until the torch kindled at his birth has been extinguished : and, like the Jewish Samson, Nisus cannot be overcome as long as the mystic locks of hair remain unshorn. The tale of Perseus is repeated in that of his descendant Heracles, but so is that of Sigurd in the legend of Ragnar Lodbrog. Thus the Hellenic and the Norse tales have each their own significance ; but they all point in the same direction. It is the same story of the struggling and toiling sun, producing fruits for the children of men, conquering his enemies but conquered himself by an inexorable fate. Procris, in the Athenian legend, is the child of Hērā the dew, Eos is still the morning, Seléné is still the moon, Endymion is the son of Aëthlios the toiler, Phaethon is still the brilliant child of Helios, the sun. Judging, then, from the evidence before us, we should be led to infer that where the Greek spoke of Perseus, the slayer of Medusa, as being the child of Danaë, the ancestors of the Greek had spoken of the sun, the destroyer of night, as the child of the golden dawn ; that when the Homeric poets spoke of the death of Achilles and Meleagros, their fathers had spoken of the brief but magnificent career of the short-lived sun. It is clear, therefore, that if adequate evidence for such a form of speech could be found, it would furnish the key to the mythology not only of the Greek, but of the Teuton, the Scandinavian, and the Persian. Under the head of LANGUAGE it has been shown that the discovery of Sanscrit rendered a science of comparative philology not only possible, but certain. The same discovery supplied the mythological key which had been so long sought in vain. This key is furnished by the earlier Vedic hymns. (Max Müller, *History of Sanskrit Literature*.) In these hymns, Kephelos, Procris, Hermes, Daphné, stand forth as simple names for the sun, the dew, the wind, and the dawn, each recognised as such, yet each endowed with the most perfect consciousness. In these hymns, when the night comes, the people say, ' Our friend the sun is dead : will he rise ? will the dawn come back again ? ' and thus we see at once the death of Heracles or Kephelos, and the weary waiting while Leto struggles with the birth of Phœbus. When the day comes back, the cry, ' Rise ! our life, our spirit is come back,' carries us at once to the Homeric hymn and the joyous shout of all the gods when Phœbus springs to life and light in Delos. In these early songs, the dawn is a maiden loved by Indra, from whose pursuit she flies, as Daphne fled from Apollo, and the tale of Orpheus and Eurydike appears in its earlier dress as the legend of Urvasi and Purāravas. The morning with its early breeze exhibits the germ of the tale of Hermes, and betrays the first sign of the faithlessness of Helen. [PARIS.] At once, names which in Greek mythology had defied all analysis become transparently clear. The Kentaurus or CENTAURS are the Sanscrit Gandharvas, the bright clouds in whose arms the sun reposes

as he journeys through the sky. Ixion, the lawless lover of Hērā, is identified with the Sanscrit Akshirān, the being who turns on a wheel, the four-spoked cross seen in the heavens at noon tide.

But it is obvious that language which might be both innocent and beautiful when applied to the sights and sounds of the natural world, might assume incongruous, repulsive, or disgusting phases, when these sights and sounds are anthropomorphised. Thus Œdipus like Perseus slays his grandsire, and as Heracles is in the end reunited to Iolē, is afterwards solaced with the love of Iocastē (Jocasta). But Iocastē is his mother : and the application of Greek ethical sentiment converted the legend into an appalling tale of incest, disaster, and ruin, until in the end Antigonē comforts him in his dying hour, as Iolē, Briseis, and Cēnonē stand at last by the side of those who had loved them and forsaken them. Of such legends the *Iliad* and the *Odyssey* present only varying forms ; how closely these forms resemble each other, can be determined only by an analysis of those poems, for which we have here no space ; but such an examination seems to warrant the conclusion that not only in the chief incidents of the story, but in the personal characteristics of Achilles and Odysseus, of Paris and Helen, of Phaethon and Telemachos, the Homeric poets worked on materials which came to them as a heritage from times long since passed away. They might embellish the materials, but they could not, and assuredly they have not, in each case, departed from the type set before them. It would follow, then, that the characters which they portrayed are not in strictness of speech national, or indeed even human. We have nothing to warrant the conclusion that the fierce wrath of Achilles and Odysseus was ever exhibited by Achaian chieftains ; and if we attempt to explain the tale by a reference to national character, we find ourselves utterly unable to explain why they fix on the methods which they choose for accomplishing their vengeance and winning their victory ; why, for instance, Achilles, like Meleagros, should choose inaction as the mode of avenging himself, and why he should make a vow not to rest until the blood of human victims should flow on the funeral pile of Patroclus, or why, again, Penelopē should weave and unweave her web [HYPERBORÆANS], and why she should refuse to see her husband until the evening, and then test him by bringing before him the beautiful tapestry which he had woven for her long ago. [RISHU, TEN SEVEN.]

Thus, then, in India and Greece, in Norway, Germany, Scandinavia, and Persia, we have a mythical system which is essentially the same ; in which the most striking names and incidents, the most remarkable details and imagery, are repeated with wonderful closeness. We find this parallelism in the legends of races who have certainly had no communication with each other since they assumed the form of distinct

MYTHOLOGY

nations, and who in all other respects exhibit very few (if any) common characteristics; and if we find that their most complicated epic poems disclose the same framework which is seen even in the most fragmentary legends, if we find that the adventures or the inaction of their heroes are simply the result of an inevitable process going on in all kindred languages, then all charges of immorality founded on the character of these adventures fall at once to the ground. It is simply impossible that such poets as Æschylus and Sophocles were descended from a people who, some centuries before, had deliberately sat down to invent ridiculous or loathsome fictions about the gods and heroes whom they worshipped and revered. In the Vedic mythology, Prajapati, the lord of creation, did violence to his own daughter; but Kumārila was ready with an explanation which the science of comparative mythology has established as incontestable. (Max Müller's *History of Sanskrit Literature*, p. 530.) The legend of Erichthonius, the coarsest perhaps in the whole range of Greek mythology (Apollodorus viii. 1. 46), resolves itself into a few mythical phrases as beautiful as they are innocent and pure; and all mystery therefore is removed from that strange combination of repulsive legends with a sensitive morality which is exhibited in the Hesiodic poem of the Works and Days. These legends lay bare to us, in fact, the workings of the human mind from a time indefinitely transcending all historical memorials whatsoever; and so clear is the light thus thrown on the earliest phases of human thought, that in the judgment of Professor Max Müller 'the idea of a humanity emerging slowly from the depths of an animal brutality can never be maintained again.'

The object of this brief sketch of the results already attained by the science of comparative mythology, will have been fully attained if it leads the reader impartially to examine the evidence which may be adduced for and against the several proposi-

NABLUM

tions under which its conclusions may be summed up. A more complete account of the subject will be found in Max Müller's 'Comparative Mythology,' in *Oxford Essays* for 1856; *Lectures on Language*, second series, by the same author; Bréal, *Hercule et Cacus*, and *Le Mythe d'Œdipe*; Cox's *Tales of the Gods and Heroes*, and *Tales of Thebes and Argos*; Dasent, *Popular Tales from the Norse*; Grimm, *Deutsche Mythologie*; Welcker, *Göttenlehre*; Creuzer, *Symbolik der Alten Völker*; Kelly, *Indo-European Folklore*, &c.

Mytilaceans (Gr. μυτίλος, Lat. mytilus, a mussel). The name of the family of Lamellibranchiate Molluscs having the genus *Mytilus*, or common mussel, for its type, and characterised by the mantle being open anteriorly, and by having a foot either sufficiently developed for the office of progressive motion, or serving to draw out, direct, and fix the byssus.

Mytilus (Lat.). A name applied by Linnæus to all Testaceous Vermes which have a bivalve shell, rough, and generally affixed by a byssus, with a hinge, mostly without teeth, generally with a subulate, excavated, longitudinal line. The species comprehended under the above phrase are placed by Cuvier in the Testaceous order of Acephalous Molluscs, and have been subdivided into the genus *Mytilus* proper (of which the common edible mussel, *Mytilus edulis*, is an example); *Modiolus*, Lam.; *Lithodomus*, Cuv.; *Anodonta*, Brug.; *Avicula*, Brug.; and *Meleagrina*, Lam., which produces the most precious pearls. Extensive establishments are maintained at Ceylon and other places for the express purpose of collecting the *Meleagrina margaritifera*, or pearl oyster.

Myxine (Gr. μύξα, mucus). The name of a genus of Cyclostomous fishes, remarkable for their mucous slippery integument: the species called *glutinous hag* (*Myxine glutinosa*) is a native of the British seas; its habits are parasitic, and it is most commonly met with in the interior of a cod upon whose flesh it has been preying.

N

N. One of the liquid series of letters. It is common to all known languages, and is interchangeable, more particularly in the Latin, Greek, and other cognate languages, with a variety of letters. As an abbreviation, N is used for *north*, *numero*, &c.; N.B. for *notu bene*; N.L. for *non liquet* (i.e. the case is not clear enough to pass sentence on); N.P. for *notarius publicus*, &c.

Nablum. One of the most famous musical instruments among the Hebrews. Its form and nature are so little known that Calmet thinks it was a harp, Kircher a psaltery

or stringed instrument of percussion played on by sticks, and Harmer (*Observations on Scripture*) hints at its being a bagpipe. Bythner (*Lyra*) says that it was like a leathern bottle, explaining his meaning to be that it bore a resemblance to the ancient Greek and Roman lyre, the body of which was made of the shell of the tortoise. The authority of Josephus (*Ant. Jud.* vii. 3. 12), if to be relied upon, distinctly shows it was not an instrument of percussion, but played upon with the fingers; his words are, ἡ νάβλα, δάδενα φόγγου ἐχουσα, τοῖς δακτύλοις κρούεται. Its having twelve

NABOB

sounds, without telling how those sounds were produced, whether by strings or wind, leaves the matter so doubtful that the reader must decide for himself.

Nabob (a corruption of *nawab*, from *naib*, a *deputy*). The title of the governor of a province or commander of an army, in India, under the rule of the Moguls. The nabob was, properly speaking, a subordinate provincial governor under the subahdar; i. e. governor of a subah, or larger province. In the decay of the Mogul empire, many of the nabobs became virtually independent, until their dominions were reduced by the English. The term *nabob* is vulgarly applied to Europeans who have amassed a large fortune in the East Indies, and live in Eastern splendour.

Nabonassar, Era of. In Astronomy, an era, followed by Hipparchus and Ptolemy, and adopted from the Chaldean astronomers, who had been in the habit of referring the observations of eclipses to the beginning of the reign of Nabonassar, the alleged founder of the Babylonish empire. This era Niebuhr (*Lectures on Ancient History* i. 29) regards as 'firmly established in history,' while he looks on Nabonassar as a prince who shook off the Assyrian yoke, and re-established the independence of Babylon. But while Niebuhr regards this fact as placed beyond all doubt, Sir G. C. Lewis (*Astronomy of the Ancients*, 428) regards the astronomical canon for the period before Cyrus as 'a complete historical puzzle,' and remarks that 'the name of Nabonassar, from whom the era is denominated, is unknown to us from any other source.' His conclusion is that the canon is referred to an arbitrary date, altogether beyond the evidence of history. Mr. Grote (*History of Greece*, part ii. ch. xix.) states that 'the earliest Chaldean astronomical observation, known to the astronomer Ptolemy, both precise and of ascertained date to a degree sufficient for scientific use, was a lunar eclipse of the 19th of March 721 a.c., the 27th year of the era of Nabonassar,' which begins with February 26, 747 a.c.

Nacarat (Span. *nacar*, *mother of pearl*). A term applied to a pale red colour with an orange cast. The *nacarat* of Portugal is a fine linen fabric, dyed fugitively of this tint. The brightest red crapes of this kind are manufactured by the Turks of Constantinople. (*Ure's Dictionary of Arts*.) [Rouge.]

Nacreite (Fr. *nacre*, *mother of pearl*). A talcose silicate of alumina, consisting of minute scales, with a glimmering pearly lustre.

Nadir (Arab. *nazeer*, *opposite*). In Astronomy and Geography, the point of the heavens diametrically opposite to the zenith. The zenith and nadir are the two poles of the horizon.

Nenia (Lat.). A funeral dirge sung to the music of flutes. The Romans personified *Nenia*, her chapel being built outside the walls near the Viminal gate; her worship was probably designed to procure rest and peace for the dead.

NAME

Nevus (Lat.). A spot or mark upon the skin of children at birth.

Nagelsbake (Ger.). A Swiss and Italian deposit of the Miocene or middle tertiary period, part of it being magnificently developed at the celebrated hill of the Superga near Turin. The rock is generally a mass of conglomerate, and is locally very thick.

Nagyagite. A native telluride of lead and gold, found at Nagyag and Offenbanya, in Transylvania.

Naiads (Gr. *Naiades*, a word akin to *nao*, I flow; *naus*, a ship; Lat. *nare*, to swim; the Sanscrit root being *na*, to wash). In Greek Mythology, female deities who presided over fountains, rivers, brooks, &c. The number of these goddesses was indefinite. [Nymphs.]

Naiadaceae (from *Naias*, one of the genus). A group of aquatic inconspicuous monocotyledons, found both in salt and fresh water. [FLUVIALS.]

Nail (Ger. *nagel*, Gr. *ὄνυξ*). This term is given to the terminal horny appendage of the finger and toe when they are in the form of flattened or depressed plates, serving to support a broad tactile surface, as in the human fingers. When these appendages are compressed, curved, pointed, and extended beyond the digit, they are called *talons* or *claws*, and the animal bearing them is said to be *unguiculate*; when they encase the extremity of a digit like a box, they are called *hoofs*, and the animal is *ungulate*.

Nais (Gr. *naïds*, a *naïad*). The name of a genus of minute Abranchiate Anellides, or red-blooded worms, remarkable for their powers of reproducing parts of the body when mutilated; and for procreating their kind by spontaneous separation of the hinder segments of the trunk.

Naked Flooring. In Architecture, the timber work of a floor, which supports the boarding, or ceiling, or both of these means of covering.

Name (Lat. *nomen*, Fr. *nom*). The designation by which any individual is known. The custom adopted in personal nomenclature has been based on some uniform principle since the earliest ages; modified, however, by the varying circumstances of different countries, and according to the more or less advanced state of civilisation of every people. Thus in the early state of society of the Jews, Egyptians, Persians, Greeks, Romans, Germans, Gauls, Britons, and indeed of every nation; no one had more than one name; but in a more advanced period one or more additional names were given, in order to mark the different families to which individuals belonged, as well as to distinguish members of the same family from each other. To effect these objects the ancient Romans, at least those of good family, generally used three names—the *prænomen*, the *nomen*, and the *cognomen*; the first, which was given on the assumption of the toga virilis, marked the individual, like our Christian name; the second distinguished the gens, and

the third the *FAMILIA*, to which he belonged. To these, however, was sometimes added a fourth name, called the *agnomen*, derived from some distinguishing peculiarities in each individual's character or condition; thus Publius Cornelius Scipio was named *Africanus*, from his exploits in Africa. The mode of designation adopted in all the countries of modern Europe is founded on a principle somewhat analogous to that of ancient Rome; with this prominent difference, that in the former no *nomen* or *clan* appellation intervenes between the *prænomen* (or Christian name) and the *cognomen* (or surname). [SURNAMES.]

Nandu. The name of the American ostrich (*Rhea americana*). [RHEA.]

Nankeen. A yellowish or buff-coloured cotton cloth, largely manufactured at Nankin in China. Its colour is that of the cotton wool of which it is manufactured. They are sometimes bleached, and then are called *white nankeens*. Imitation nankeens are manufactured at Manchester; but these are confessedly of an inferior quality to the Chinese, neither lasting so long, nor holding their colour so well.

Nantes, Edict of. [EDICT.]

naos or Nave (Gr. *naos*, a house or temple). In Architecture, that part of a temple which is enclosed by the walls. The part in front of it was called the *pronaos*, the part that occupied the rear being called the *posticum*. In modern ecclesiastical architecture the term *nave* is applied to the middle part or alley of a church, between the aisles or wings, to the west of the transepts and choir.

Naphtha. This term, originally applied to one of the products of the distillation of pit coal, has been extended to a variety of native hydrocarbons, issuing often in large quantities from fissures in connection with coal strata and in other localities. The Burmese petroleum or naphtha has long been celebrated; it issues from a sandy loam resting on bituminous shale, and coal strata, and is used in lamps, and mixed with earth for fuel.

Enormous quantities of naphtha, under the name of *rock oil*, have been imported from Canada and from the United States. The Mecca wells of Ohio are sunk in a sand-stone saturated with the oil, and have yielded from twelve to twenty barrels of oil daily. One of the Canadian wells is said to have yielded a thousand gallons an hour, much of which ran to waste from want of means to store it. These supplies are apparently inexhaustible, and have led, as already stated, to large importations into this country, where the oils are used for various purposes. It need scarcely be observed, that on account of the ready and dangerous inflammability of all these products, careful precautions against fire are requisite in the warehouses in which they are stored.

When these oils are subjected to fractional distillation they are separable into several distinct hydrocarbons, and they differ in composition and in specific gravity accordingly;

that of rock oil varies from 0·830 to 0·890, and their boiling points are liable to corresponding variations. (Mansfield, *Quart. Journ. Chem. Soc.* i. 252; De la Rue, *Proceedings of the Royal Society*, viii. 221.)

Naphthalene or **Naphthalin.** This is a solid hydrocarbon = $C_{10}H_{10}$, formed during the destructive distillation of pit coal for the production of gas. It is obtained by redistilling the coal tar. It is a white crystalline substance, heavier than water, and of a peculiar aromatic odour. It is extremely volatile (fusing at 180°), and its vapour condenses in large white flaky crystals. It burns with much smoke. It is soluble in alcohol and ether. This substance has given rise to an infinity of compounds with acids, chlorine, bromine, &c. none of which are of practical importance, but curious in reference to the substitution of compounds, and to the nomenclatural difficulties in which they are involved. (Miller's *Elements of Chemistry* iii. 667.) In some of our gas-works naphthalene is occasionally formed in such quantities as to produce much inconvenience by plugging up the service pipes.

Naphthalic Acid. *Phthalic Acid.* A crystalline product obtained by the action of nitric acid on naphthalin: it has also been similarly obtained from alizarin.

Napier's Bones or Rods. An instrument contrived by Lord Napier, the inventor of logarithms, for facilitating the performance of multiplication and division. It was described by Napier himself in his *Rabdologia*, Edinburgh 1617; a short explanation is also given in the *Penny Cyclopædia*. Although interesting as a curiosity, the instrument is practically useless.

Naples Yellow. A celebrated yellow pigment, formerly made by a secret process at Naples, and used not only in oil painting, but as an enamel colour; it is said to be a mixture of the oxides of antimony, lead, and zinc.

Napoleon, Code of. In 1802, during the temporary calm of the Peace of Amiens, Napoleon, then First Consul, undertook the great task of forming a civil code. It was intrusted to a commission of the council of state; of which Tronchet, Rœderer, Portalis, Thibaut-deau, Cambacérès, Lebrun, were the leading members. 'Tronchet' (said Napoleon himself to Las Cases) 'was the soul of the code.' (*Memoirs*, part iii. 234.) Portalis has also the credit of an important share in its composition. But Napoleon himself took great interest in the subject, and mingled eagerly in the discussions of the commission, as appears by the *procès-verbal* of those discussions. After all allowances made for the unparalleled flatteries of the Napoleonists, his remarks are said to show great intuitive sagacity, much readiness, and a peculiarly enquiring disposition, which often led him to the principles of things, while men of less natural power and trained in a different school, were busying themselves unprofitably with the matters on the surface. 'I had at first fancied,' he says, 'it would be possible to reduce all laws to simple geometri-

NARCOEIA

cal demonstrations, so that every man who could read and connect his ideas together would be able to decide for himself; but I became convinced almost immediately after that this idea was absurd.' (Las Casas, *Mem.* part vi. 263.) Still, according to himself, he continued to cherish the scarcely less absurd idea that no other laws might be necessary than those inserted in the code. The second volume of the work of Thibaut (sur le Consulat et l'Empire) is perhaps the most useful to consult for the history of these discussions. According to him, the secretary Loucé did not in any degree improve the speeches of the First Consul in his report. Although the ideas of Napoleon himself are said to have entered largely into the composition of the code, it does not appear clearly in what important particulars this was the case; except in one singular instance, that of the law of divorce (book i. title 6), the liberty of which he is said to have greatly promoted. The Code Civil is composed of a great number of laws, dated from the '14 Ventose, an 11' (March, 1803), to 24 Ventose, an 12 (March, 1804), in which latter month they were united in a single code; and which was republished under the empire in 1807. The 'Code de Procédure Civile' was put in force on the 1st of January 1807; the Code of Commerce dates from the same year; the 'Code d'Instruction Criminelle' from November 1803; the 'Code Pénal' from February 1810; which last is a revision of the 'Code Pénal' and 'Code des Délits et des Peines' of the Revolution. But the 'Code Civil' is that to which the term 'Code Napoléon' is in common language particularly applied. It consists of three books; the first 'of persons,' subdivided under eleven titles; the second 'of goods (biens), and the different modifications of property,' comprising four titles; the third 'of the different manners in which property is acquired,' with twenty titles. These last are again subdivided into chapters and sections; and the whole code consists of articles numbered in arithmetical order through the whole, in all 2281. The most important provisions of the code as to the civil state of persons are those relating to marriage and divorce. With regard to property, its fundamental law is that of equal succession by heirs, the abolition of most distinctions between landed and movable property, and the restraint imposed by it on the testamentary power. In the general character of its system, the Code Napoléon merely consolidated the revolutionary laws already existing. [CODE.]

Narceia (Gr. *νάρκη*, numbness). One of the vegeto-alkaline bases, contained in opium, and discovered by Pelletier in 1832. Its medical virtues have not been ascertained. Its composition is said to be $C_{22}H_{26}O_{11}N$. [OPIMUM.]

Narcissus (Gr. *νάρκισσος*). In Botany, a genus of Endogenes belonging to the natural order *Amaryllidaceae*, among which it is known by its flowers growing upon a scape, and having a cup at their mouth, the stamens opposite the

NARCOTINE

sepals being longer than the others. The species are very numerous; and from their delicate shape, soft and various colour, and sweet scent, have long been favourite objects of cultivation, especially the Daffodils, Jonquils, and Tazettas. Some of the more hardy species grow wild in our woods and under our hedges; but the finer sorts are natives of more southern latitudes. They are divided into several groups or subgenera, of which the principal are: *Ajax*, the Daffodils; *Ganymedes*, the Rush Daffodils; *Hermione*, the Polyanthus Narcissi; and *Queltia*, the Mock Narcissi.

NARCISSUS. In Mythology, the beautiful son of Kephissus and the nymph Liriope. The legends connected with his name are by no means consistent. According to one version, he was insensible to the feeling of love, and Echo, failing to win his affection, died of grief; as a punishment, Nemesis made him fall in love with his own image, reflected in water, and Narcissus in his turn pined away from unsatisfied longing. The story of his metamorphosis into the flower, so called, is given only in the version adopted by Ovid, and this version says that he killed himself, and that the flower sprang from his blood; while Pausanias, earnestly combating the proposition that Narcissus was so stupid as to be unable to distinguish a man from a man's shadow or image, maintains that he looked at his image in a well to remind himself of a sister whom he had loved and who had died. He is sure, however, that the flower existed before Narcissus, because Persephoné was gathering narcissi in the fields of Enna when she was stolen away by Hades. To so devout a believer in the supernatural, the proof was conclusive; but these inconsistent versions show at the least that the idea of an actual metamorphosis was of comparatively late growth.

Narceogenine (a product of narcotine). A basic substance resulting from the oxidation of narcotine.

Narcotics (Gr. *νάρκη*). Medicines which produce drowsiness, sleep, and stupor. Some of them appear, in the first instance, to act as stimulants, quickening the pulse, and rousing the energy of the nervous system; and, in very small doses, this is their most obvious operation. In larger doses these effects are followed by a tranquil state of mind, torpor, and even coma. Considerable skill and experience are required in the successful administration of these medicines, both as regards the cases in which they are to be prescribed, the doses in which they are to be given, and the peculiarities of habit which often interfere with and modify their usual effects. They are to be distinguished from *sedatives*, which do not produce preliminary excitement. Opium is a narcotic, henbane a sedative. [ANODYNES; HYPNOTICS.]

Narcotine (Gr. *νάρκη*). ($C_{48}H_{74}O_{15}N$). A crystallised substance, obtained by digesting opium in ether. It was discovered in 1803 by Derosne, and supposed to be the narcotic principle of opium; but this has since been shown to

NARD

reside more exclusively in *morphia*, and narcotine is possessed rather of stimulant qualities, and is the cause, perhaps, of the excitement which opium occasions; the statements, however, as to its medicinal action are much at variance. Narcotine is almost insoluble in water and in weak solutions of ammonia and potash. Alcohol and ether dissolve it, but not very freely. It fuses at 268°, and concretes into a crystalline mass on cooling.

Nard (Gr. *νάρδος*). The Nard of the ancients, or Spikenard as it is usually called, is now believed to have been the produce of a dwarf Valerianaceous herb, found in Nepal, and known to botanists as the *Nardostachys Jatamansi*. The roots are said to be very fragrant.

Nardoo (its native name). The *Narsilia macrospora*, or, as it is sometimes called, *N. salutaris*, the spores and spore-cases of which are pounded by the native Australians and made into bread or porridge.

Narration (Lat. *narratio*). In Rhetoric, the term usually applied to the second division of an oratorical discourse, in which the facts of the case are set forth from which the orator intends to draw his conclusions.

Narthex (Gr. *νάρθηξ*). The first section or division in the Roman basilicas, allotted especially to the monks and to women, and used for rogations, supplications, night-watches, and as a place for the dead during the performance of the funeral rites. The catechumens, the *energumani* (or persons supposed to be possessed by evil spirits) and the *lapsi* (or persons who had denied their faith during times of persecution) were also restricted to this part of the building. The baptistery was distinct from the narthex, being reckoned among the *cardae*, or appurtenances of the basilica. (Hook's *Church Dictionary*.)

NARTHEX. The genus of Umbellifers from which the drug Asafetida is obtained. [ASAFETIDA.]

Narwhal. The common name of the species of Cetacean which has a single long protruded tusk. [MONODON.]

Nasal (Lat. *nasus, nose*). A nasal pronunciation is given in some languages to particular letters, as in French to the letters *n* and *m* in certain positions. The only sound approaching to nasal in English is that of the double consonant *ng*; as in *thing, ring, &c.*

Nasalis. [SEMNOPTHECUS.]

Nascent State. Chemists generally apply this term to gaseous bodies at the moment of their evolution, as it were, from liquids or solids, and before they have assumed the æriform state. There are numerous cases in which bodies, having no tendency to combine under ordinary circumstances, readily unite when presented to each other in their nascent states. Hydrogen and nitrogen gases, for instance, when mixed together, show no disposition to combine; but when certain organic bodies containing those elements are heated, they are evolved in their nascent states, and combine so as to form ammonia; it is in this

NATION

way that ammonia is abundantly produced during the destructive distillation of many kinds of animal matter, and of pit coal. Hydrogen gas has no action, under ordinary circumstances, on sulphur or on arsenic; but when sulphide of iron or arsenide of zinc are acted on by dilute sulphuric acid, the hydrogen, at the moment of its evolution, combines with the sulphur and arsenic to form sulphuretted and arsenuretted hydrogen. The destructive distillation of organic substances in general furnishes abundant and important instances of these nascent combinations.

Nasturtium (Lat.). The scientific name of a genus of Cruciferous plants of weedy character, some of them found in this country, the most important being the Water-cress, *N. officinale*. It is also a popular or garden name for the *Tropæolum* or Indian Cress, doubtless from some fancied resemblance in its properties to those of the true *N*.

Nasum (Lat. *nasus, a nose*). A genus of Plantigrade Mammalia, so called from the remarkable elongation and upward curve of the nose. The species of this genus, *N. rufa*, or red coat, and *N. fusca*, or brown coat, are both natives of South America. They climb trees in pursuit of birds, and to rob their nests; they burrow for shelter at the foot of large trees, and often undermine them to such an extent that they are liable to be overturned even by a slight wind.

Nasuta (Lat. *nasus*). A term in Zoology, signifying the prolongation of the muzzle into the form of a nose, as in the *Peromyscus nasuta*, *Pleurocytus nasutus*, *Truxalis nasutus*; or the development of the integument of the face above the muzzle, forming a true nose, as in the *proboscis* monkey, *Simia nasuta*. Illiger called a family of Multungulate quadrupeds with the nose prolonged beyond the jaws, and movable, as in the tapir, *Nasuta*.

Natatores (Lat. from *nato, I swim*). Swimming birds. The name of the order of birds including those in which the toes are united by a membrane, whence the order is also termed *Palmpedæ*. The legs are placed behind the equilibrium, and the body is covered with a thick coat of down beneath the feathers. [ANSERIS; ANATIDÆ.]

Natatory. In Zoology, a term used to denote that a locomotive extremity, or other part, is provided with a membrane, or with close-set hairs, by which it is adapted for displacing water.

Nation (Lat. *natio*, from *nascor, to be born*). A collective appellation for a people inhabiting a certain extent of territory under the same government. The word is also used in some universities, by way of distinguishing students of different districts or countries, as the case may be. This latter meaning is borrowed from the custom of the university of Paris previous to the institution of faculties, when those who resorted to it from different countries lived under the same institutions

NATIONS, LAW OF

and masters; a *common country*, however, being the only bond of union.

Nations, Law of. [Law.]

National Debt. In Finance. Under the names of benevolences and loans, the English sovereigns had for centuries increased, whenever necessity pressed them, such resources as could be derived from their estates, from their feudal rights, and from parliamentary taxation. It is hardly needful to say that these debts were rarely repaid, and that parliamentary supervision over such parts of the revenue as were applied to the public service was, except in rare cases, unpractised and unknown. When these methods of raising funds were declared illegal, monarchs sometimes resorted to violence, as Charles I. and Charles II. did in the seizure of the merchants' and goldsmiths' deposits; sometimes they borrowed on their personal security, as Charles I. borrowed from the colleges of Oxford and Cambridge, from the Cavaliers, and the loyal corporations; sometimes they sold their possessions, as Charles II. sold Dunkirk; sometimes they even submitted to be the annuitants of foreign sovereigns, as the same monarch was of Louis XIV. A parliamentary guarantee was out of the question, for the effective existence of such a security implied the collateral necessity of parliamentary superintendence and control, and a far greater political independence than the house of Stuart could have endured, or indeed ever suffered. Had the course of events which led to the Revolution taken a different turn, James II., who was an economical and thrifty sovereign, might perhaps have so husbanded his ample revenue as to have rendered himself at once independent of his parliament and of Louis. But the Revolution threw the crown entirely into the hands of the House of Commons, and made the monarch, by virtue of its fundamental principles, wholly dependent upon the people for his supplies. Public debts had been created by the Dutch long before the era of the Revolution, and there cannot be a doubt that if an effectual guarantee had been possible, securities analogous to those created at the Revolution would have been negotiated during the Spanish and civil wars, and even during the time in which the nation was bent on recovering the Palatinate.

It is true that at the Revolution the new settlement was in great danger, but it may be doubted whether the danger was really understood. At the present time, when the worthlessness of most of the persons who joined the standard of William is known, it is quite possible to be wise after the event; but it is not likely that the public were alive to the perfidy of the men who, surrounding the throne of William, made ardent professions of loyalty, and all the while corresponded with the court at St. Germain. The intrigues of Louis XIV. and the defence of the Netherlands were the occasions by which the new parliamentary system was enabled to assert its authority

NATIONAL DEBT

over the revenue, to give the most satisfactory pledge of its power, by inducing subscriptions on the part of the mercantile public for the relief of government necessities, and to prove itself, in great degree at least, the expressed voice of the people at large. It is impossible to conceive the existence of a national debt, except on the hypothesis of parliamentary independence, because, unless the nation be personally pledged to the obligation, the security is worthless.

In order of time, the oldest part of the national debt is the composition made to the bankers for the seizure of their deposits, i.e. 1,328,526*l.*, in the Exchequer on the 6th of January, 1672. To still the panic which ensued upon this robbery, the king promised to pay interest at the rate of six per cent. on the sum appropriated; but, as might be expected, he broke his word, paid no interest, took no steps to liquidate the obligation, and the bankers nearly thirty years afterwards were obliged to accept a composition, by which interest at the rate of three per cent. was secured on the debt, with the option of redemption on repayment of half the principal. The actual debt was thus reduced to 664,263*l.*, and nearly the whole was absorbed in the subscription of the South Sea Company's stock in 1720, thus forming the earliest part of the national debt, being that only which was increased before the Revolution.

It has been observed above [*FUNDS, PUBLIC*], that originally the word *fund* was applied to the source from which the means for paying interest and (where the debt was terminable) the principal were to be derived, and that much of the public debt, when interpreted according to the amount originally contributed to the exigencies of government, is fictitious. [*FUND, SINKING.*]

During the greater part of the eighteenth century, loans were negotiated in a number of stocks. For instance, the subscriber of 100*l.* received a certain amount in consolidated annuities at three per cent., a certain amount in a four or five per cent. stock, and a terminable annuity. Hence the creation of that which was called *long annuities*; the extinction of which has been a considerable relief to the revenue of late years. But it has been found that the terms on which long annuities have been granted have been exceedingly disadvantageous to the borrowers, the worth of the annuity having been generally far in excess of the money advanced. This was still more notably the case in government life annuities; in regulating which, the government habitually granted an annuity worth fourteen years' purchase when the actual value of the life was not more than ten years' purchase.

The bank of England has always negotiated the government loans, and received a fixed sum for the same. Originally the interest on the several funds was paid at the Exchequer. But part of the South Sea scheme was the consolidation of all the funds, with a view to their being managed by the company, who were

NATIONAL DEBT

to make themselves responsible for the interest. Gradually the whole management of the debt, the payment of interest, the circulation of Exchequer bills, and all the other offices connected with the financial acts of the government, have been conferred on the Bank, which receives a stated annual sum in compensation, with the use of the Exchequer balances remaining in their hands. This payment is 300*l.* per million on 600 millions, and 150*l.* per million on all above 600 millions. Thus, in 1863 the Bank received 180,000*l.* for the first-named portion, and 20,224*l.* for the management of 134,827,423*l.* The payment of interest on the government annuities forms another item in the expense of management, this payment being provided for at the National Debt Office.

The public debt is divided into that contracted for Great Britain and Ireland; each of these heads is further subdivided into permanent funded debts and terminable annuities, and again into the various stocks, created either by original loan, consolidation, or reduction, with charges of interest on each portion. This state of the debt on March 31, 1863, is given in Table I. with the purpose of exhibiting the form in which the debt and charges are presented to parliament in the annual volume of miscellaneous statistics.

The debt has grown during periods occupied by foreign wars. This gradual growth is shown in Table II. with the diminutions which have been effected in its amount during times of peace. The redemption amounts to less than ten per cent. upon the capital created. For the expedients which have been from time to time adopted, for the purpose of liquidating public obligations either in whole or part, see **FUND, SINKING.**

It is not possible to separate from the ordinary consequences of taxation in general the effects of so large an annual deduction from the profits of the nation, in order to meet the interest to be paid on those public debts which have been created upon the guarantee of national honour. These profits are at present mulcted to the extent of twenty-six millions a year; and if it were possible to free industry from so vast an incumbrance, and to permit the accumulation and productive employment of so large an amount of a nation's annual earnings, it would seem that industrial efforts would be recompensed by a far larger share of prosperity than they can attain under the pressure of such enormous annual obligations. But though taxation diminishes the quantity of enjoyments possessed by the contributor, it does not follow that it cripples the collective energy of a nation. It may, and often does happen, that taxes paid to government are deductions from unnecessary expenditure, and that the proceeds of these taxes are devoted towards the maintenance of labour, and even of productive labour. If indeed a war expenditure is rendered necessary in order to support the independence or political existence of a nation, however much the charges may press upon individuals, its effect

on a community is rather to displace a portion of profit, which may have been spent as well as saved, from particular persons, in order to invest it in permanent advantage to the nation at large. Government expenditure, even for war, is not necessarily a public loss, however just it may be that war should not be undertaken except under the pressure of overwhelming necessity, and should be, as far as its burdens and charges are concerned, so distributed as to affect as evenly as possible all classes alike. The pressure of the interest on the public debt is to be considered, therefore, much more as affecting the power of expenditure possessed by individuals, than as really affecting national resources. [**TAXATION.**]

Unlike almost all other nations, the English people has consistently recognised the sanctity of its public obligations; and if repudiation has ever been recommended, it has been by obscure persons, who have been met by indignation or contempt. Sometimes indeed it has been argued that the act of a generation by which it pledges posterity to the liquidation of debts incurred in the interest of a bygone policy, or a temporary advantage, is not and should not be binding on posterity. But such reasoning ignores the greatness of the inheritance which has been received from our ancestors, and is of the same nature as the morality which would accept the estate of another, and dispute the debts which have been contracted for the purpose of defending, improving, and securing the estate. Even if the political action of our forefathers was not wise (and much if not by far the greatest part of the national debt was contracted for unreal or illusory objects), supposed value was taken by the act, and real value received for the obligation. So if an heir received an inheritance from his ancestor, and on taking possession discovered that large debts were due from the estate, for instance, in consequence of extravagant expenditure on an election, no one would admit the plea that the futility of the purpose for which the liabilities were incurred, or the folly of the ancestor, entitled the heir to dispute or deny the debt, if the debt were bona fide, and for value legally received. It is just indeed that those who have received the largest share of the inheritance, or have derived the greatest advantage from the outlay, should be liable to the largest portion of the obligation.

In the debates which took place at the conclusion of the Continental war, many persons advocated the resumption of cash payments, in a depreciated currency, suggesting for instance that the sovereign should contain fifteen shillings' worth of gold only, and urging that as gold had stood for several years at a premium equivalent to such a depreciation, and as large part of the public debt had been created in paper having a forced circulation, it was just that the payment of the interest on the debt should be made at the actually low, and not at the nominally high rate in which the securities were originally funded. The plan failed, and most righteously. Only one part of the state-

NATIONAL DEBT

ment was true, and all the reasoning was fallacious. It was true that a large, but certainly not the largest, part of the existing debt had been created in a depreciated paper. But the terms on which the loan was made implied, according to parliamentary guarantee, a resumption of cash payments within a year after peace was declared; and it is matter of history that steps were not taken to redeem this pledge till three years after the occurrence of peace, and even then that very gradual justice was done to the fund-holder. Again, during the whole time that the paper was depreciated, the holders of all stocks created before the war, and before the Bank paper was at a discount, were paid in a medium which reduced the actually receivable dividend by the full amount of the depreciation, and so had inflicted a considerable wrong on the public creditor. In short, the scheme, amounting to a repudiation of a fourth of the national debt, was as sophistical as it was dishonest, and would have been assuredly suicidal.

Real reductions have been made in the amount of the debt by diminutions in the rate of interest. By far the largest portion of the debt consists of permanent annuities, analogous in their nature to a perpetual mortgage, in which the mortgagee foregoes his right of demanding payment, but the mortgagor retains the privilege of extinguishing his obligation by repayment. Hence when the price of the security exceeds its nominal value, it becomes possible to create a new debt for the purpose of extinguishing the old, the new debt being negotiated at a lower rate of interest. At different periods, advantage has been taken of the high value of public securities to perform this operation. This was first done on a large scale, after several previously ineffectual attempts, in 1749, and the fund created formed the basis of the consolidated annuities, of which more than half the public debt consists. Of late years a $2\frac{1}{2}$ per cent. stock has been formed.

The actual burden of the public debt and the virtual reduction of its incidence are relative to the annual income of the nation. Obligations once exceedingly onerous are now comparatively easy, because the wealth and ^{its} of the nation have so largely increased. At the peace of 1815, the charge of the debt absorbed the greater portion of the annual revenue; at the present time, although reduced in amount by little more than six millions, it does not form much more than a third of the expenditure, the larger revenue being derived with less difficulty and far less personal sacrifice than during the years which followed on the cessation of the great European war.

It would seem that the best means by which debt can be cancelled, is by the creation of long annuities. There is very little difference in market value between an annuity of 100 years and a perpetual payment, although of course the difficulty of estimating

the present value of a long annuity by an individual renders it next to impossible that such securities should be circulated widely among the general public. But there is a class of institutions peculiarly fitted for the negotiation of such securities, namely insurance and finance companies, who, it may be supposed, on certain advantages being offered, might be induced to make considerable investments in long annuities, and be able to recoup themselves by the creation of a reserve corresponding to the annual depreciation of the principal sum. At present only about 17 millions of public debt is in the course of liquidation by these means.

Public securities present certain advantages to investors, and are protected by certain privileges. No duty is levied on purchase and sale; brokers are obliged to transact business for their clients in public stocks at certain fixed rates; and till lately personal property in the hands of trustees, which they were not expressly authorised by the instrument of trust to invest otherwise, was compulsorily invested in consols. Besides, consols may be, and constantly are, pledged in order to procure bankers' advances, and so to a great extent fulfil the function of deposit accounts. But it may be doubted whether these securities are ever likely to be at par again. So many new advantageous, and apparently safe objects for the investment of capital have been and are discovered, and the principle of limited liability is being applied so extensively to commercial undertakings, and is absorbing savings on so large a scale, that the attractions of these investments come powerfully into competition with the feeling and desire of security which led to the selection of consols. The fact is significant, because if consols remain permanently below par, the prospect of reducing the incidence of the debt by conversion into stock of a lower denomination is finally shut off, and the only means by which the amount can be lessened will be by the continual excess of income over expenditure, or by the adoption on a large scale of a system of long annuities, by which the extinction at some future time of a large portion of debt will be effected at a small increase of annual payment for a period.

The liability of each person, in the population of the several European states, towards the public debt, is greatest in Great Britain and Ireland, and least in Switzerland; in the former amounting to 27*l.* 1*s.*, in the latter to 1*s.* 3*d.* The Netherlands come after England, and next France. The French debt is on this calculation less than half the English proportion. On the other hand, the burden of interest is higher proportionately in France than in Great Britain; for though the English debt is so large, it must not be forgotten that its magnitude is due to the fact, that, unlike almost any other, this country *has never* (with the exception of part of the banker's debt, already noticed) *repudiated any of its obligations.*

NATIONAL DEBT

TABLE I. *Amount of each DESCRIPTION of the PERMANENT PUBLIC FUNDED DEBT, and of the TERMINABLE ANNUITIES, in GREAT BRITAIN and IRELAND respectively, and of the UNFUNDED DEBT of the UNITED KINGDOM, with the Amount of ANNUAL INTEREST PAYABLE ON EACH KIND OF DEBT, on March 31, 1863, and the AMOUNT PAID for the MANAGEMENT of the PERMANENT DEBT in the same Year.*

Description of Debt	Rate of Interest	Amount of Debt	Annual Interest
GREAT BRITAIN.			
Permanent Funded Debt:—	Per cent.	1863 £	1863 £
New Annuities	2½	2,949,667	73,741
Consolidated Annuities	3	400,237,351	12,007,120
Reduced Annuities	3	114,198,564	3,425,956
New Annuities	3	213,130,895	6,393,296
Bank Debt	3	11,015,100	330,453
New Annuities	3½	240,746	8,426
Ditto	5	430,603	21,530
Exchequer Bonds	2½	418,300	11,503
		742,621,226	22,272,025
<i>Estimated Capital of Debt.</i>			
Terminable Annuities:—			
Annuities for life		10,099,660	1,017,668
Annuities for terms of years		639,979	76,200
Annuities 4 Geo. IV. c.22 expiring April 5, 1867		2,168,719	585,740
Red Sea Telegraph Company's Annuity, expiring August 4, 1908		818,199	36,000
Red Sea Telegraph Company's Annuity, expiring April 5, 1885		84,794	12,127

NATIONAL DEBT

TABLE II. *Amount of the Principal and Annual Charge of the Public Debt at different Periods since the Revolution.*

	Principal, Funded and Unfunded	Interest and Management
Debt at the Revolution, in 1689	£ 664,263	£ 39,855
Excess of debt contracted during the reign of William III. above debt paid off	15,730,439	1,271,087
Debt at the accession of Queen Anne, in 1702	16,394,702	1,810,942
Debt contracted during Queen Anne's reign	37,760,661	2,040,416
Debt at the accession of George I., in 1714	54,145,363	3,351,358
Debt paid off during reign of George I. above debt contracted	2,053,125	1,133,807
Debt at the accession of George II., in 1727	52,092,238	2,217,551
Debt contracted from the accession of George II. till the peace of Paris in 1763, three years after the accession of George III.	86,773,192	2,634,500
Debt in 1763	138,865,430	4,852,051
Paid during peace, from 1763 to 1775	10,281,795	380,480
Debt at the commencement of the American war, in 1775	128,583,635	4,471,571
Debt contracted during the American war	121,267,993	4,980,201
Debt at the conclusion of the American war, in 1784	249,851,628	9,451,772
Paid during peace, from 1784 to 1793	10,501,380	243,277
Debt at the commencement of the French war, in 1792	239,350,148	9,208,495
Debt contracted during the French war	601,500,343	22,829,679
Total funded and unfunded debt on February 1, 1817, when the English and Irish Exchequers were consolidated	840,850,491	32,038,174
Debt cancelled from February 1, 1817, to January 5, 1854	85,538,790	4,163,515
	755,311,701	27,874,659
Debt created by Russian war, 1855-9	68,623,199	652,824
	823,934,900	28,527,483
Cancelled to 1863	6,395,583	2,295,692
Debt and charge, March 31, 1863	817,539,317	26,231,791

See, for the earlier portion, Grellier's *History of the National Debt*; and for the later, Porter's *Progress of the Nation*.

National Defence. The defence of a state or a nation against invasion. The short distance of our shores from those of France rendering us peculiarly liable to invasion in case of hostilities with that country, the best method of national defence for England has been the theme of much contention. Forts, iron-clad ships, larger armies, have been advocated. Within the last few years, large sums of money have been spent on the national defences. Our dockyards are being strongly fortified; iron-clad ships have been built for the defence of our coasts; and large bodies of volunteers have been trained, who could be rapidly massed at one spot, by means of our railways, in the event of a threatened invasion. But it must not be forgotten that all history shows that irregular troops can never successfully oppose regularly disciplined soldiers; and too great a reduction of the standing army should on no account be attempted, while all the powers abroad are so fully armed. To

build fortifications without soldiers to hold them, to mount guns without gunners to man them, is useless.

Native Amalgam. A native alloy of quicksilver and silver. It occasionally forms perfect crystals, and is found at Almaden in Spain, Rosenau in Hungary, Moschellandsberg in Deux Ponts, Chili, &c.; chiefly it is said, at the intersection of veins of mercury and silver.

Nativity. In Astrology, a term synonymous with Horoscope.

Natrix (Lat. a *water-snake*). The subgenus of the Linnæan *Colubri*, of which our common harmless snake, *Coluber Natrix*, Linn., is the type.

Watrolite. Prismatic Zeolite. A hydrated silicate of alumina and soda, which occurs in slender or acicular crystals, and in small mammillary fibrous masses of a white, yellowish, or greyish colour.

Watron. Native carbonate of soda has long been known under this name, and hence the term *natrium*, applied to sodium by the German chemists, which has led to the adop-

NATURAL

tion of the symbol Na for that metal. It is found in sandy soils of various countries, but more especially in Egypt, where it was anciently employed in the art of embalming. [MUMMY.] It occurs also in Africa, near Fezzan, under the name of *trona*, at Maracaibo in South America, and in large quantities in the plain of Debreczin in Hungary, and elsewhere.

Natural. In Music, a character marked thus ♮. Its office is to contradict the flats or sharps placed at the beginning of a stave or elsewhere, and by its use the note to which it is prefixed returns to the natural scale of the white keys.

Natural History. The history and description of the natural products of the earth, whether minerals, vegetables, or animals, together with a scientific development of their causes and effects. The several branches of this subject are treated under their respective heads.

Natural Orders of Plants. In Botany, the groups of genera which are supposed to bear a greater resemblance to each other than to anything else. They may be said to be coeval with our knowledge of plants; for the old ideas of grasses, trees, herbs, corn, and fruit trees, indicate a perception of the existence of some such groups. When systematical botany first assumed the appearance of a science, we find the Umbelliferous, Leguminous, Liliaceous, Labiate, and Composite orders, more or less distinctly defined. It is, however, chiefly to the labours of botanists posterior to the days of Linnæus, especially to Jussieu and his followers, that we owe the present improved limitation of natural orders. The most complete account of them in English is in Lindley's *Vegetable Kingdom*, in which 303 natural orders are defined. [BOTANY.]

Natural Philosophy or Physics. The science which treats of the properties of natural bodies, and the action of their masses on each other. [PHYSICS.]

Naturalisation. In Law, the process by which an alien is placed in the same civil condition as if he had been born under the dominion of the state. In England, this could formerly take place only by Act of Parliament, but by stat. 7 & 8 Vict. c. 36 an alien may obtain a certificate from one of the principal secretaries of state, conferring on him all the rights and capacities of a natural-born British subject, except those of sitting in parliament and being a member of the privy council. [ALIEN.]

Nature Printing. The art of reproducing and printing on paper botanical specimens of flowers, leaves, or of whole plants, so truthfully that the microscope may detect in the print peculiarities too minute to admit of imitation by any effort on the part of the engraver. The art was first practised by M. Auer, superintendent of the Imperial printing office in Vienna, and was introduced into this country by the late Mr. Henry Bradbury.

VOL. II. 641

NATURE PRINTING

The subject to be printed is first *thoroughly* dried by placing it between thick blotting paper, and pressing it in a screw press, frequently changing the paper, and repeating the process until all moisture is extracted; in some instances the services of the sun, or even of artificial heat, are additionally called into requisition. When it is thoroughly dried (and this fact may be ascertained by its brittleness), it is ready for manipulation. The plant may be said to engrave its own plate in this wise: a thick piece of pure soft sheet lead, rather larger than the paper on which the subject is ultimately to be printed, must be planed as bright and even as a looking glass. It may be here mentioned, that Mr. Bradbury found this his only difficulty—and his efforts were for a time completely paralysed; for although the process was perfect in other respects, the plates were *ribbed*, as it is termed, and, when printed, gave impressions of a large number of latitudinal lines not intended to be in the subject. In this exigency he applied to Mr. James Wood, who, by an adaptation of the knife so as to polish and cut at the same time so soft a substance as lead, constructed a machine by which tons of plates have been since satisfactorily planed. Upon the bright prepared lead plate the subject is laid in the position required, and is then passed between powerful rollers of polished steel, until the plant is embedded in the lead, and a fac-simile matrix is the result. Great care and patience now become requisite, the subject having to be disinterred without injury to the lead plate; this is done piecemeal, and the blow-pipe is found to be of great use in burning the particles which cannot easily be got out otherwise; and, as some of the more delicate portions of the lead plates would become fused, and consequently useless, just sufficient flame only is applied to consume the dried fibres. One or two impressions can now be obtained from the lead plate by the copper-plate press, but of course the softness of the lead renders another process necessary for securing large quantities of impressions. The back and edges of the lead plate are therefore covered with a varnish, the face only being left exposed; it is then suspended in an electrotype depositing trough, and a deposit of copper thrown on it, and allowed to remain until the copper has grown to an eighth of an inch in thickness; the lead plate and copper impression are then separated, the copper relief plate in its turn undergoes the varnishing of the back and edges, to prevent the adhesion of superfluous copper, the face being well black-leaded with the purest plumbago (to prevent the two copper plates from incorporating); the relief plate then undergoes the same operation that the lead plate underwent, the result being another deposit the reverse of the first. These in their turn have to be separated, and the climax is arrived at, viz. the production of an engraved copper plate ready for the printer, who inks the plate in such a manner as to represent nature as nearly

T T

as may be, the leaves being green, and the stems and roots brown; he then pulls his impression upon unusually soft paper at an iron copper-plate press, the paper sinking to the full depth of the plate, and an embossed printed picture is the result. (Wood's *Typographical Advertiser*.) The *Ferns of Great Britain and Ireland*, with Text by Lindley and Moore, is one of the most beautiful specimens of this kind of printing.

Nauca. In Botany, a seed in which the scar of the hilum occupies one third part of the external surface, as in the horse chestnut.

Naucrary (Gr. *ναυκραπία*). Before the time of Solon the naucraries were political divisions of the Athenian people answering to the Demi of the constitution of Cleisthenes. Up to this time they had no connection with the navy, the name probably being derived from *valeu*, to dwell, and *κλῆρος*, a lot, with the simple meaning of householder. Afterwards, each naucrary was made answerable for providing a ship of war, and this duty was ultimately developed into the Trierarchy. [ΛΙΤΩΒΕΥ.]

Naunium (Lat. from Gr. *ναῦλος*, *passage-money*). In the usage of the ancient Greeks and Romans, a piece of money put into the mouths of deceased persons to enable them to pay Charon for ferrying them over the Styx.

Naumachia (Gr. *a sea-fight*). Among the Romans, a representation of a naval engagement, which took place most usually in theatres (called also naumachiae) made for the purpose. These exhibitions were originally instituted for purposes of naval discipline; but, in process of time, only malefactors or captives whose lives had been forfeited acted in them. They appear to have been conducted on a scale of such magnificence as almost to exceed belief. Within the places set apart for them whole fleets went through their evolutions. In the sea-fight on the lake Fucinus, given by Claudius, there are said to have been no fewer than 19,000 combatants. Julius Cæsar appears to have first given a naumachia on an extensive scale; his example was followed by many of his successors on the imperial throne; and at last they were frequently exhibited at the expense of private individuals, as a means of increasing their popularity. The seats for the convenience of spectators were arranged in a manner somewhat similar to those in the amphitheatres. [ΑΜΦΙΤΗΑΤΡΕΩ.]

Naumannite. A native selenide of silver found at Tilkrode in the Harz; and named after Naumann, the Saxon mineralogist.

Nausea (Gr. *ναῦστος*, *qualmishness*, from *ναῦς*, a ship). A sensation of sickness, similar to that produced by the motion of a ship at sea. An inclination to vomit.

Nautilidae. The family of Cephalopods with siphoniferous shells, of which the *nautilus* is the type.

Nautilus (Gr. *ναῦτιλος*, literally *a sea-man*). The name of a genus of Tetrabranchiate Cephalopods, including those which

have a chambered shell with simple septa, perforated in the centre, concave towards the outlet of the shell, the last chamber being the largest, and containing the body of the animal.

Naval Architecture. The science of designing the forms for vessels, in order that they may properly fulfil the purposes for which they are severally intended, is distinct from shipbuilding, which is the application in practice of the theoretical designs of the naval architect.

When a ship is to be built, her form is projected in three different planes perpendicular to each other.

1st. The *sheer draught*, which is the side view, or projection on the plane of the keel. On this are laid off the length, the heights of all the parts from the keel, the position and rake of the stem and stern post, the principal frames or timbers of the sides, the ports, decks, channels, place of the greatest breadth or midship frame, stations of the masts, &c.

The frames before the midship frame are distinguished by letters; abaft it, by numbers.

The midship frame is not exactly in the middle of the length, but rather before it.

2nd. The *body plan*, or end view. This shows the contour of the sides of the ship at certain points of her length; and since the two sides are exactly alike, the left half represents the vertical sections in the after part of the body, and the right half those in the fore part. The base of the projection is the midship, or largest section, called also the *dead flat*, within which the other sections are delineated. On this are exhibited also the beams of the decks.

3rd. The horizontal or floor plane, called also the *half-breadth plan*. The base of this is the section made by the horizontal surface of the water and the outside surface of the ship, and is called the *upper water line*, or *load water line*. If the ship now be supposed to be lightened uniformly, she will exhibit another water-line, and thus any number of like parallel sections at equal distances down to the keel.

These three sections correspond to each other upon the same scale; and any point in one is immediately referable to the other two projections.

The sheer draught plan shows length and height, the body plan breadth and height, the half-breadth plan breadth and length. Thus the three dimensions are given each on two plans for every point of the outer frame of the ship.

The water-lines, or lines parallel to the surface of the water, appear on the sheer draught as straight lines parallel to the keel or the upper water-lines; in the body plan, as straight lines at right angles to the keel; and on the half-breadth plan as curved lines.

The lines representing the timbers, or exterior of the cross sections of the ship, appear as curves in the body plan, and as straight lines at right angles to the keel in the other two plans.

NAVAL ARCHITECTURE

The several parts are drawn from these plans in their full size on the floor of the mould loft, and worked by the practical ship-builder from the moulds or models so taken. A sketch of some of the operations by which the actual ship is produced from the designs of a naval architect will be given under **SHIP-BUILDING**.

The forms of ships vary according to the object for which the vessel is built, and according to the ideas of the architects; for although great steps have been made in this science, it must be confessed that in many points it is still empirical. Results occur which the designers did not anticipate, and the most successful vessels are not always those which by theory should attain the palm. Formerly the vessels of the royal navy, copied from French prizes, were our best models, but in recent years the merchant service has equalled if not surpassed the navy in improvements, great as has been the advance made by the latter. The large clippers built for the Australian trade and the magnificent steamers for ocean navigation have opened a new era in ship construction. The principal improvements have been in the direction of giving increased length, sharper prows, rounder bottoms, and therefore lower centres of gravity.

Numerous experiments have been made to ascertain the best forms for ships. The results may be shortly summed up as follows:—

1. The resistance of the water against the heads of ships varies as the areas of midship sections immersed and as the weights.

2. The centre of lateral resistance is at the middle point of the keel when the ship floats level and is at rest. As speed increases, the centre of lateral resistance moves towards the bow.

3. Stability is increased by increased width and by increased length in an arithmetic ratio. The maximum as regards depth is attained when the depth immersed is one-fifth the beam.

4. Sharper bows give greater speed than bluff bows, and a gently curved line than a straight line. The resistance is also diminished by the sides of the bow being bevelled from the water-line towards the keel.

5. Speed is augmented by the sides tapering in from the midship section backwards towards the stern. This also adds to the steering power. The bottom should also curve up from the midships section towards the stern.

6. Speed is increased by additional length.

7. The immersed portion of the midship section gives most speed when semicircular, least when triangular. A flat rectangle gives most stability, a triangle the least. The flat rectangle draws least water for a given burden, the triangle the most.

8. The pressure for lee-way is as the area of the sheer plan immersed.

9. All lines where resistance has to be overcome should be gently convex.

NAVIGATION

10. The midship section from which curves start for bow and stern should be nearer to the bow than stern.

11. In all steam vessels the portion amidships devoted to the engine room should float the engines, boilers, and fuel, and nothing else. The ship should therefore be computed for her intended duties, divided in the middle, and the engine room there inserted.

Naval Cadets. Boys training for service as naval combatant officers. They enter between twelve and fourteen years of age, and are required to pass a simple examination. After two years' service the naval cadet becomes a midshipman.

Naval Crown. Among the Romans, a crown, of gold or silver, resembling the prow of a ship, awarded to the man who first boarded a hostile vessel. [Crown.]

Naval Reserve. An auxiliary naval force formed in 1859 under 22 & 23 Vict. c. 40 for men, and 24 & 25 Vict. c. 129 for officers. It consists of masters of merchant vessels (certificated) as lieutenants, chief mates as sub-lieutenants, and men of all ranks in the merchant service. The men enroll themselves for five years, and are bound to train for twenty-eight days in each year in a ship of war or with the coastguard, as directed. While training they receive naval pay, and as a retaining fee 6*l.* a year. In case of national emergency the reserve may be called out for service in her majesty's ships in any part of the world for a period not exceeding five years. After about the age of forty-five a man of the reserve becomes entitled to a pension of 12*l.* for life, or to a smaller sum for the longest liver of himself and wife. If he have actually served for three years, he is entitled to 2*d.* a day additional.

The officers receive while training or serving, lieutenants 10*s.* a day, and sub-lieutenants 7*s.* a day, with pensions for wounds and (if killed in action) to widows at the same rates as in the royal navy.

The establishment sanctioned by the Acts is 400 officers and 30,000 men. About half that force has been actually enrolled.

Naos. [Naos.]

Naue of a Wheel (Ger. nabe). The centre part of a wheel. It is usually made solid, and from it the spokes radiate.

Navicular (Lat. navicula, a little boat). Boat-shaped. The *navicular* bone is one of the bones of the tarsus. The term is also used in Botany.

Navigation (Lat. navis, a ship). That branch of science by which the mariner is taught to conduct his ship from one port or place to another.

To understand the principles of navigation, and their practical application, it is necessary that the mariner should be acquainted with the form and magnitude of the earth, the relative situations of the lines conceived to be drawn on its surface, and that he should have charts of the coasts and maps of the harbours which he

NAVIGATION

may have occasion to visit. He must also understand the use of the instruments for ascertaining the direction in which a ship is steered and the distance which she sails; and be able to deduce from the data supplied by such instruments the situation of his ship at any time, and to find the direction and distance of any place to which it may be required that the ship should be taken.

A curve passing through any two places on the earth, and cutting every intervening meridian at the same angle, is called a *rumb line*; the angle which such a curve makes with each meridian is called the *course* between any two places through which the curve passes; and the arc of that curve intercepted between any two places is called their *nautical distance*. This distance is more than that measured on the arc of a great circle passing through the two places, unless both places are on the same meridian, or both on the equator, when the rumb line and great circle coincide.

The *difference of latitude* between any two places is an arc of a meridian intercepted between the parallels of latitude on which the places are situated; and the *difference of longitude* is the arc of the equator, or the angle at the pole included between the meridians of the places. Hence, when the latitudes or the longitudes of two places are of the same denomination with respect to *north* or *south*, *east* or *west*, the difference is found by subtracting the less from the greater; but when of different denominations, what is called their difference is found by taking their sum. [LATITUDE; LONGITUDE.]

When a ship has sailed on a rumb line from one meridian to another, the arc of the parallel at which the ship has arrived, intercepted between the two meridians, is called the *meridian distance* which the ship has made; and the sum of all the intermediate meridian distances, computed on the supposition that the distance sailed on the rumb line is divided into indefinitely small equal parts, is called the *departure*.

In the annexed diagram, let P represent the north pole; DE an arc of the equator; PD, PF, PG, and PE meridians, and A B a rumb line passing through A and B; A S, K H, L I, and B C, arcs of parallels of latitude at the points A, H, I, and B respectively; and let A H, H I, I B, &c. be so small and so numerous that neither they nor A K, K H, H O, I O, &c. may differ sensibly from straight lines. Then if a ship sail from A to B, B C is called the meridian distance; if from B to A, A S is called the meridian distance; and in either case the sum of K H, O I, N B, is called the *departure*; and A K + O H + I N, &c., which is always equal to A C or B S, is the *difference of latitude*.

Now, A K H, O H I, N I B, &c., may be considered as right-angled plane triangles; and if in the annexed plane triangle, right-

angled at C', A' B' be taken equal to A B in the preceding figure, A' C' to A C, or to its equal A K + H O + I N, and the angle B' A' C' to B A C, or O H I, or N I B, then C' B' in this figure would accurately represent K H + O I + N B, &c. in the preceding one. That is, in the plane triangle A' B' C', right-angled at C', if A' represent the course from one place to another, A' B' the distance of the two places measured on the rumb line passing through them; then A' C' will be their *difference of latitude*, and C' B' the *departure* made in sailing from the one to the other.

On these principles depends what is called *plane sailing*; and it is evident that if any two of the four elements, *course*, *distance*, *difference of latitude*, and *departure*, be given, the others may be found by the solution of a right-angled plane triangle. The formulæ are:

$$\begin{aligned} \text{dep.} &= \text{dist.} \times \sin \text{course,} \\ \text{diff. lat.} &= \text{dist.} \times \cos \text{course,} \\ \text{dist.} &= \text{dep.} \times \text{cosec course,} \\ \text{dist.} &= \text{diff. lat.} \times \sec \text{course,} \\ \tan \text{course} &= \frac{\text{dep.}}{\text{diff. lat.}} \end{aligned} \quad (\text{A})$$

When a ship sails on a meridian, the diff. lat. is the same as the nautical distance, and the *latitude* only, not the *longitude*, is changed; and when a ship sails on a parallel of latitude, the departure is the same as the nautical distance, and the *longitude* only, not the *latitude*, is changed: but it is evident that in sailing in any other direction both the latitude and longitude are changed.

For finding the change of latitude corresponding to any course and distance, the principles of plane sailing, already explained, are sufficient; but to find the change of longitude corresponding to any given change of place, considerations of a different kind are needed.

Let a ship sail on a parallel of latitude, as from C to D, and let P C A, P D B, be two meridians passing through C and D, and meeting the equator in A and B; then A B, or the angle A P B, is the difference of longitude, corresponding to the distance C D sailed on the parallel in the latitude A C or D B. And if F be the centre of the sphere, A F B, C E D, portions of the planes of the equator and parallel respectively, we have, by similar sectors,

$$\begin{aligned} \frac{AB}{CD} &= \frac{BF}{DE} = \frac{FD}{DE} = \text{cosec } PD = \sec BD = \sec \text{ lat.} \\ \text{or } AB &= CD \sec \text{ lat.} \end{aligned}$$

i.e. difference of longitude = distance \times sec lat. Hence, again, if in the annexed plane triangle M N O, right-angled at N, the angle M be made equal to the number of degrees and minutes of the latitude of the parallel on which the ship is sailing, and M N be equal to C D, M O in this figure will be equal to the arc A B in the preceding one, and will

NAVIGATION

consequently represent the difference of longitude; for

$$MO = MN \sec M = CD \sec \text{lat.}$$

Therefore, in sailing on a parallel, the properties which connect the latitude of the parallel, the distance sailed upon it, and the corresponding diff. long. are all found in a right-angled plane triangle; the base representing the distance sailed on the parallel, the hypotenuse the diff. long., and the included angle the latitude of the parallel.

When a ship sails on an oblique rhumb, two methods have been proposed for connecting the other elements with the diff. long.: one called the *middle latitude method*; and the other, from the name of its inventor, *Mercator's sailing*.

Middle latitude sailing is a compound of plane and parallel sailing. Referring to the first figure in this article, it is evident that KH is greater than CM, but less than AQ; that OI is greater than MN, but less than QR; and that KH + OI + NB will not differ greatly from the meridian distance midway between the parallels CB and AS.

The departure corresponding to course c , and distance d , being therefore found from $\text{dep.} = d \sin c$, and this being taken as a meridian distance in the latitude $\frac{1}{2}(l + l')$, the middle latitude between the latitude l sailed from and l' arrived at, the diff. long. is found approximately from the principles of parallel sailing, from the formula,

$$\text{diff. long.} = \text{dep.} \sec \frac{1}{2}(l + l').$$

From this, and from the first and last of the formulæ (A), we immediately deduce the following for middle latitude sailing, viz.:—

$$\text{diff. long.} = \frac{\text{dist.} \times \sin \text{course}}{\cos \text{mid. lat.}}$$

$$\tan \text{course} = \frac{\text{diff. long.} \times \cos \text{mid. lat.}}{\text{diff. lat.}} \quad (B)$$

$$\text{dep.} = \text{diff. long.} \times \cos \text{mid. lat.}$$

In *Mercator's sailing*, the globe is conceived to be extended from the equator towards the poles, so as to form a cylinder whose diameter is that of the equator; the corresponding elementary parts of the meridians and parallels, as projected on the cylindric surface, bearing the same proportion to each other with the like corresponding parts on the spherical surface; the projected rhumb lines being straight lines, and the poles vanishing in infinite distance. Such a cylinder, unrolled on a plane, is called a *Mercator's chart*. Now, considering the earth as a sphere, the meridians and the equator are equal great circles, and therefore any small portion of a parallel is to a like portion of the meridian in the same proportion as the radius of the parallel to the radius of the equator; and therefore the elementary portion of the meridian divided by the corresponding portion of the parallel will be equal to the secant of the latitude. If, therefore, m represent the

length of an elementary portion of the meridian at latitude l , and m' be the projection of m on Mercator's chart, then, generally, $m' = m \sec l$.

It follows from this that in Mercator's projection the degrees of latitude, which at the equator are equal to those of longitude, increase with the distance of the parallel from the equator proportionally to the secants of the latitudes. The parts of the meridian thus increased are called *meridional parts*; and it is a property of the projection that the meridional parts of any given latitude are equal to the sum of the secants of the minutes in that latitude. [MER-CATOR'S CHART.] The sum of the secants being computed for every minute up to any latitude, l , and tabulated, forms what is called a table of *meridional parts*; and the difference, or the sum of the meridional parts corresponding to the latitudes of any two places, is called the meridional diff. lat. of those places, the *difference* being taken when the latitudes are of the *same*, and the *sum* when of *different* denominations.

It is likewise a remarkable property of Mercator's projection, that any triangle on the sphere is represented on the chart by a similar triangle, the angles of the original triangle and its representation being equal. Hence the ship's path on the sphere and its projection on the chart cut the meridians under the same angle. If, therefore, ABC be a triangle on the sphere, AC being a portion of the meridian, and A'B'C' its projection; then A'B' and A'C' will be in the same direction with AAB and AC, and B'C' will be parallel to BC. In these triangles, therefore, the course A is an angle common to both; AC is the diff. lat., A'C' the meridional diff. lat., CB the departure, C'B' the diff. long., AB the distance run, and A'B' the distance as projected on the chart, the same scale being used for measuring all the lines in the diagram. Hence, from such parts of these triangles as may be determined by observation, or taken from tables, the others may be computed by the common rules of plane trigonometry.

The following formulæ are obvious consequences of this construction:—

$$\text{diff. long.} = \frac{\text{dep.} \times \text{mer. diff. lat.}}{\text{diff. lat.}}$$

$$\tan \text{course} = \frac{\text{diff. long.}}{\text{mer. diff. lat.}} \quad (C)$$

$$\text{distance} = \text{diff. lat.} \times \sec \text{course.}$$

The course of a ship at sea is determined by the *compass*. [COMPASS.] The needle generally rests in a position pointing northerly and southerly; and the angle which its direction makes with the true north and south line is called the *variation of the compass*, the variation being denominated *easterly* or *westerly*, accordingly as the north end of the needle is to the east or west of the true north.

NAVIGATION

The amount of this deviation differs greatly in different situations; and it is by no means a constant quantity even at the same place. There are, however, simple astronomical means of finding it at any place; so that, by applying a correction for the variation, either the true course may be gained from an observed compass one, or the compass course from a computed true one.

Besides the general *variation* to which we have here adverted, it is found that in ships which have large masses of iron on board, or which are themselves constructed of iron, the compass is sensibly attracted, and the effect varies with the direction of the ship's head. The effect on the compass for different positions of the ship's head is discovered by swinging the ship and noting the difference of reading off between a compass placed on shore beyond the influence of the iron, and that of the compass on board. [DEVIATION OF THE COMPASS.]

The velocity of the ship, or the *rate* of sailing, is determined experimentally, at the end of every hour, by heaving the *log*. [Log.] For changes of velocity between the times of heaving the log, the officer on duty makes the best estimate he can.

When the wind is adverse or changeable, it is often requisite to sail on different courses; and the crooked line which the ship then describes is called a *traverse*. The method of finding a single course and distance equivalent to such a compound one is called *resolving a traverse*.

This may be done by a geometrical projection, but it is generally effected in practice by the aid of the traverse table. From this table the *diff. lat.* and *dep.* corresponding to each course and distance is taken, and entered in an appropriate table, having columns headed N. S. E. W.; namely, N. and S. for *diff. lat.*, and E. and W. for *departure*. The difference between the sums under N. and S. shows the *diff. lat.*, as does the difference between the sums under E. and W. the *departure*; and in either case the difference is of the same denomination as the larger sum. The course and distance required are then either found by inspection in a traverse table, or by the formulæ (A).

When a ship makes considerable way through the water, and the wind is on the beam, abaft it, or even a little before it, she generally moves forward in the direction of the fore and aft line; but in rough weather, with the wind forward, she will generally be driven more or less to leeward, as will be shown by the direction of the wake, or the ripple formed by the waves closing behind her. The angle which this ripple makes with the direction of the keel is called the *leeway*; and it must be applied as a correction to the course shown by the compass, and always allowed *from* the wind—that is, to the left, if the wind is on the right-hand side of the ship, and to the right, if on the left. [LEEWAY.]

All matters relating to the navigation of a ship are entered in a systematically ruled book,

called the *log-book*; and that which day after day is so recorded is called the ship's *journal*. The principal columns in the log-book are for the hour of the day, the course, rate of sailing, leeway, and winds; one for general remarks, and for entering the particulars and results of celestial observations, for notes on the weather, and memoranda as to all important points of duty in the ship, the sails set, and the manner in which the crew are employed. To this is daily appended the latitude and longitude of the ship at noon, both as deduced from celestial observations, and as computed from the course and distance since the time when the place was last ascertained. The place determined from the course and distance is called the place by *dead reckoning*. The bearing and distance of the land first expected to be seen, and the course and distance made on the whole, during the day, are also added.

If the course and distance could always be accurately determined, the place of the ship could be computed with corresponding exactness from the principles of which we have above given a concise account. But these data can only be obtained in a roughly approximative form. The effect of unknown currents, unavoidable imperfections in steering, and numberless other sources of error, render the place of the ship, as estimated from the reckoning, very doubtful; and, in fact, when the mariner is obliged to rely for several days on these data only, he often finds that his expected and his true place are considerably distant from each other.

In the modern practice of navigation, therefore, the course and distance are only used to enable the seaman to assign approximately the place of his ship between the times at which it is determined, independently, by celestial observations.

This branch of nautical knowledge, which is generally and properly included in every system of navigation, is called *nautical astronomy*; and the improvements which have been introduced in its modern application constitute the chief difference between navigation as practised in our own and former times.

For a minute explanation of the processes by which the place of a ship on the wide ocean may be determined, from the observed situation of celestial objects with respect to each other and to the horizon, we must refer to works expressly devoted to the subject. But we shall give a short account of the most useful practical methods of finding the *latitude*, the *longitude*, and the *variation of the compass*, which are the three principal problems in nautical astronomy.

Reduction of Altitudes.—Before the altitudes of celestial objects as observed at sea can be employed in the solution of astronomical problems, they must be corrected for the effects of dip and parallax; and for semidiameter, when the altitude of the upper or lower border, instead of that of the central, has been observed, as in the case of the sun or moon.

NAVIGATION

If A = the altitude of the upper or lower border, s = the semidiameter, d the dip of the horizon (that is, the angle through which the sea horizon appears depressed in consequence of the elevation of the observer), r the refraction corresponding to the alt. A , and p the horizontal parallax taken from the *Nautical Almanac* for the time of observation, and A' = the true altitude: then

$$A' = A - d \mp s + p \cos (A - d \mp s) - r.$$

In practice, the corrections to be applied to A to obtain A' are taken from tables, and the process of reduction is short and simple.

To find the latitude from the observed meridian altitude of a known celestial object:

Let z be the complement of the true altitude as deduced from the observed one, D the object's declination, and L the latitude; and call s north when the zenith is north, and south when it is south of the object: then $L = z \pm D$; a formula in which D is + when z and D are of the same, and - when of different denominations, and L is of the same denomination as the greater of z and D .

To find the latitude from two observed altitudes of the sun, with the time elapsed between the observation:

Let t = the half elapsed time in degrees, p the sun's polar distance at the middle instant between the observations, s = half the sum, and d = half the difference of the two corrected altitudes; then compute the angles A, B, C, D , and E , in succession, from the following formulae:—

$$\begin{aligned}\sin A &= \sin t. \sin p. \\ \cos B &= \sec A. \cos p. \\ \sin C &= \operatorname{cosec} A. \cos s. \sin d. \\ \cos D &= \sin A. \sin s. \cos d. \sec C. \\ E &= B \mp D.\end{aligned}$$

And the expression for the latitude is,

$$\sin \text{lat.} = \cos D. \cos E.$$

There are many other methods by which the latitude may be found, but the two which we have given are those most generally used by seamen.

We pass on to a consideration of the principles on which the methods of finding the longitude astronomically at sea are founded.

The longitude is found by comparing the time at the first meridian with the time of the same denomination at the place of observation, allowing 15° of longitude for every hour in the difference of the times.

In the annexed diagram, let PA represent the meridian passing over the first point of *Aries*, PS that passing over the true and PM that passing over the place of the mean sun, and PX that passing over any

other celestial object X . Let also PG be the meridian of Greenwich, PN a meridian in west longitude, and PO a meridian in east longitude.

Then for that instant of absolute time, APG

represents the *sidereal*, SPG the *apparent*, and MPG the *mean* time at Greenwich; twenty-four hours of time being represented by four right angles. APN, SPN , and MPN , are the *sidereal*, *apparent*, and *mean* time at the meridian PN ; and APO, SPO , and MPO , the like times at the meridian PO .

Now NPG , the longitude of the meridian PN , = $APG - APN = SPG - SPN = MPG - MPN$; and GPO , the longitude of PO , = $APO - APG = SPO - SPG = MPO - MPG$.

Therefore, the longitude of any place represented in time is equal to the difference of the relative times at the first meridian and the meridian of the place; the times being both *sidereal*, both *apparent*, or both *mean* time, and both reckoned from the same noon—*west* when the Greenwich time is *greater*, and *east* when it is *less* than the time at the place of observation.

The angle XPG , reckoned westerly from PG , is called the meridian distance of the object X from the meridian PG , and XPN its meridian distance from the meridian PN . APX is its right ascension, APS the right ascension of the sun, and SPM the *equation of time*, or the difference between mean and apparent time.

Now, if a be the altitude of an object X , as observed in a given latitude l , say on the meridian PN , and $p = PX$ its polar distance; then, if we put $s = \frac{1}{2}(a + l + p)$, the angle XPN may be determined from this expression, $\sin \frac{1}{2}(XPN) = \sqrt{[\sin(s-a) \cdot \cos s \cdot \sec l \cdot \operatorname{cosec} p]}$. And $XPN + APX - APS \pm SPM = MPN$, the mean time at the meridian PN .

PX, APX, APS , and SPM , are furnished by the *Nautical Almanac*; and it is evident, therefore, that from an observed altitude of a celestial object, with the data supplied by the *Nautical Almanac*, the *mean time* at the place of observation may be found.

With respect to the corresponding Greenwich time, it may be found by means of a chronometer, whose error and rate are ascertained before it is taken to sea. For example, if on May 4 the chronometer be 4m. fast for Greenwich time, and on May 14, 4m. 50s. fast for Greenwich time; then, if on May 30, at sea, an altitude be observed to determine time at the place of observation, when this chronometer shows 5h. 46m. 12s., then the true mean time at Greenwich is 5h. 40m. 2s.; and if the mean time at the place deduced from the observation be 3h. 57m. 48s., the longitude of the place will be 5h. 40m. 2s. - 3h. 57m. 48s. = 1h. 42m. 14s. = $25^\circ 33' 30''$ west.

The Greenwich time may also be found by considering the moon in the heavens as the pointer of a Greenwich clock, and her distances from the sun and certain stars as indicating the Greenwich times to which they correspond. These distances are computed, and published beforehand in the *Nautical Almanac*, for every third hour of Greenwich time; so that if at any moment we ascertain the moon's distance from some such celestial object, the Greenwich

NAVIGATION LAWS

time may be found by comparing that distance with those in the *Nautical Almanac*.

The distances there given, however, are the distances of the objects as seen from the centre of the earth; and therefore before a distance observed on the surface can be made available for finding the Greenwich time, it must be reduced to what it would have been if the observation had been made at the centre. Many formulæ have been devised, and numerous and extensive collections of tables have been formed, to assist the observer in making this reduction; but perhaps the following is as convenient as any that has been proposed.

Let z be the true zenith distance of the moon; z_s the sun's or star's; a the apparent altitude of the moon; a_s the sun's or star's; d the apparent distance of the centres of the two bodies, and D the true distance of the centres required; then D can be readily found from the following expression:

$$\begin{aligned} \text{vers } D &= \text{vers } (z + z_s) + \text{vers } (d + A) \\ &+ \text{vers } (d - A) + \text{vers } (a + a_s + A) \\ &+ \text{vers } (a + a_s - A), \\ \text{where } \cos A &= \frac{\sin z_s \sin a_s}{2 \cos a_s \cos a_s} \end{aligned}$$

The value of A has been calculated for different altitudes, and forms the table called the *table of the auxiliary angle A*, to be found in Inman's and other Nautical Tables. (See Jeans' *Navigation* for the construction of this table, and for other methods of clearing the lunar distance.)

To compute the bearing of the sun, the altitude, polar distance, and latitude being known:

Let a = the altitude, l = the latitude, p = the polar distance, $S = \frac{1}{2}(a + l + p)$, and B the required bearing, or azimuth—estimated from the south when the latitude is north, and from the north when the latitude is south; towards the east when the altitude is increasing, and towards the west when it is decreasing, then

$$\sin \frac{1}{2} B = \sqrt{[\sec a \cdot \sec l \cdot \cos S \cdot \cos (S - p)]}.$$

If the compass bearing of the object be observed when the altitude is taken, the variation of the compass may hence be found; for let B' = the compass bearing; then the variation is $B + B'$ or $B - B'$, the sign + being used when one bearing is eastward and the other westward, and - when both are on the same side of the meridian; and the variation is *west* when B is to the *left*, and eastward when it is to the right of B' .

For an account of the history of navigation, the reader is referred to the Introduction to Robertson's *Elements of Navigation*. Of modern works on this subject in general use among British seamen, we may notice those by Dr. Inman, Mr. Jeans, and Mr. Riddle, treating both of the theory and practice. The *Epitomes* of Lient. Raper, Mackay, and Norie are also very useful compilations, and have long had an extensive circulation.

Navigation Laws. In *Economical History*, the enactments made for the purpose of

securing a monopoly of the carrying trade to home shippers, either by an absolute prohibition on goods imported in foreign bottoms, or by differential duties levied on such goods. Navigation laws have also been enacted in order to regulate the right of coast and deep-sea fishing, the coasts having generally been allotted to fishermen of the country, and importation from deep-sea fisheries having been limited to such vessels as have been built in the United Kingdom, and manned by British crews.

Regulations and statutes of this character are traceable in the earliest history of English commerce, though in consequence of the connection of a considerable part of the French seaboard with this country during the era of the Norman and Plantagenet kings, the restrictions put on maritime intercourse were not very severe, and as a consequence rates of transit were low, and supplies, especially of French produce, were abundant. The origin of the modern navigation laws is to be found in the foreign policy of this country, and the hostility felt towards the Dutch in the seventeenth century.

Foreigners had been excluded from the fisheries and coasting trade by 5 Eliz. In 1650, the Republican parliament prohibited all ships built or manned in foreign ports from traffic with the American plantations, unless a license were first obtained. This measure, one rather of police than of exclusion, was followed in the next year by the famous Act of Navigation. The provisions of this Act were partly intended to secure a monopoly of European traffic, partly to promote shipping interests, and to create and sustain a large seafaring population, partly to injure the opulence, and especially the maritime supremacy of the Dutch, who had about this time well-nigh engrossed the carrying trade of the world. All produce of Asia, Africa, and America, was excluded from England, Ireland, and the colonial dependencies, except it were imported in English ships, manned by an English master and (for the most part) by an English crew. Nor could any European produce be imported, except in English ships, or in ships which were the real property of the people in whose country the exported commodity was produced, or from which alone it could be exported. It was this last clause which was intended to cripple the trade of the Dutch, whose wealth was almost entirely derived from the profits of the carrying trade. On the Restoration, the navigation law was immediately re-enacted, and till a recent period was the basis of the commercial relations entered into between this and foreign countries. So strongly impressed were the people of the time with the wisdom of the Navigation Act, that they considered it a provision second only in its beneficial effects to the great charter, calling it the *Charta Maritima*. Two years later, the Act was extended so as to apply to Germany. Certain goods, it is true, were allowed to be imported in ships of any kind or origin; but a long list of specified articles, containing the

NAVIGATION LAWS

chief kinds of bulky and raw produce, were rigorously limited to English carriers. In effect the statute was intended to prohibit commercial intercourse with a large portion of the mercantile world, and as far as this country could bring such a result about, to exclude the Dutch and Germans from the pale of trade; and though some of the regulations in the Acts of 12 & 14 Ch. II. were relaxed, the leading provisions were retained up to the late changes in the law.

The policy of the navigation laws was the object of general praise. Even Adam Smith, though he fully recognised that any limitation of the means by which the market is supplied would enhance the cost of foreign produce, and diminish the price of exported goods, and therefore would check the power of buying as cheaply and selling as dearly as possible, does not scruple to say, that 'national animosity' suggested 'regulations as wise as could have been dictated by the most deliberate wisdom.' He does not indeed argue this, as some have argued it, on the ground that the existence of British commerce depended upon the provisions of the navigation laws; but, accepting the impression that the Act provided a nursery for seamanship, and acknowledging that defence is more important than opulence, he was prepared to sacrifice cheapness in one direction in order to secure safety in another. It is very doubtful, however, whether any such results were effected by the navigation laws, or whether any such compensation has been afforded.

It does not seem that the Dutch trade was weakened by the navigation laws, or the naval superiority of the Republic diminished. It remained powerful at sea for at least a century after this Act was passed; and the decline of its commercial superiority was due to other causes than the restrictive policy of this and other communities. It is generally, but we think erroneously, assigned to the pressure of taxation on the industrial resources of the Republic. It is more naturally interpreted by the unwise regulations which were taken by the Dutch in order to maintain the price of tropical produce, and by the weakness of a community which owed its commercial greatness to no permanent advantages of position on the highways of commerce, but to the precarious distinction implied in the qualities of intelligence, activity, and thriftiness. Holland occupied its commercial position chiefly, we believe, because other nations possessed of far larger natural capacities were late in discovering and adopting those principles and practices on which mercantile prosperity depends. It was eminent because it had as yet no rival, but its precedence was lost as soon as ever it was disputed by nations of equal energy and wider resources.

Nor does it appear that the naval superiority of this country depended in the least degree on the passing and continuance of the Navigation Act. England had begun to be formidable at sea before the protective system implied in

this Act was elaborated. Drake and Hawkins and Frobisher were the true fathers of the English navy, and were bred up in the hardy school of free enterprise. Blake owed his maritime skill to other causes than the fostering care of the navigation law, and the naval pride of the Dutch was humbled before the law was enacted, and revived during the early years of its existence. Van Tromp was defeated when the highway of nations was free, and the Dutch burnt the English fleet in the Medway and insulted London when those provisions in which Adam Smith recognised the most deliberate wisdom were in force. As Mr. McCulloch has very pertinently observed, 'Navigation and naval power are the children not the parents, the effect not the cause of commerce. If the latter be increased, the increase of the former will follow as a matter of course.' Shipping is no exception to the general rule, that protected interests never thrive.

The indirect effects of our navigation laws were exceedingly mischievous, and ultimately led to a system of retaliation which would, if it had not been met by timely concessions, have seriously endangered our commerce. The Americans in 1817 copied the very words of our own Act, and prepared to carry out its provisions in their own country, avowedly in order to compensate the restrictions which our laws had put upon their trade. The northern European powers threatened the same policy, and would certainly have carried their measures into execution, had it not been for the changes introduced into our maritime code by Messrs. Wallace and Huskisson. These changes contained important alterations in the rules by which trade with the British colonies from foreign ports was governed. At present, the last step in the direction of freedom having been taken in the year 1850, the trade between the colonies and the rest of the world is completely unshackled.

Pending the entire abolition of the navigation laws (with the exception of such parts of them as refer to the coasting trade, which still remains subject to certain conditions, chiefly with the view to obviate smuggling), a concession was adopted called the reciprocity system. This had its origin in the retaliatory measures of the United States, who levied a differential duty of nearly a dollar a ton on all produce imported in foreign ships beyond that paid by American vessels. To meet this regulation, various inoperative duties were attempted and abandoned. Ultimately, by the commercial treaty of 1815, it was agreed between this country and the United States, that equal charges should be imposed on ships of either country in the ports of the other, and that equal duties should be imposed upon all articles. Similar regulations were laid upon commercial intercourse with the South American states. In 1825, in order to meet similar retaliatory measures on the part of European communities, the reciprocity system was extended to the whole world, the administration

of the Act being left, as far as its details go, to the Privy Council. This doctrine of reciprocity is also retained in the Act of 1850, with this difference, that no rule exists that a foreign country must accept the provisions of the Act previous to its being entitled to participate in its advantages. If it appears to the council that any prohibition, restriction, or discriminating duty should be enforced, it may be ordered, subject, of course, to criticism in parliament.

Lastly, the distinction between British and foreign built ships is done away. To constitute a British ship, it is not now required that it should have been manufactured in any dock of the United Kingdom. It is to all intents and purposes British, if it be the property of British owners. Hence the English merchant may employ the building yard of any country, and is therefore enabled if he see fit to buy ships, as he may buy any other product, in the cheapest market. It was said at the time when this liberty was given, that foreign builders, owing to the greater cheapness of labour, would be able to undersell the home manufacturer, and some went so far as to predict the loss of the art of shipbuilding in England. But, as is often the case, the objectors did not define cheapness by its true test, efficiency; and the prophecy has been falsified by events. [SHIPPING.]

Navire (Fr.). An order of knighthood instituted by St. Louis, king of France, in 1269, to encourage the lords of France to undertake the expedition to the Holy Land. It derived its name either from the circumstance that the collars of the knights belonging to it had a ship pendent from them, or because the knights were allowed to bear in their arms a ship argent in chief.

Navv (Lat. *navis*, a ship). Its most extended signification this term is combined both to the mercantile and military marine of a nation; but it is more commonly restricted to vessels of war only, all others being said to belong to the merchant service. In treating of the navy, it is usual to consider it under two distinct heads, the matériel and personnel: the former comprising all that relates to the construction, armament, and equipment of ships; the latter including all who receive rank, pay, or emolument in the service of the navy, and including whatever concerns the appointment, station, and duties of officers, sailors, and marines. Under the different heads the reader will find a notice of the chief subjects included in the matériel of the navy.

The naval history of Great Britain is usually divided into three eras; the first comprising all the period that preceded the reign of Henry VIII.; the second ending with the restoration of Charles II.; and the third from the Restoration down to the present time. Omitting the English naval history between the Conquest and the reign of Henry VIII. as too unimportant to be dwelt upon in a sketch like the present, we may state, before passing to the second period, that

the first monarch who maintained a naval force in time of peace was Henry VII., who also built the first line-of-battle ship of the British navy, in the third year of his reign. She was called 'The Great Harry,' had three masts, carried 80 guns (mostly, however, of trifling calibre), measured 138 feet in length, and 36 feet in breadth from outside to outside, and cost upwards of 14,000*l*. This ship constituted the most noble monument of the regard of Henry VII. for the navy; but his designs were matured by his son Henry VIII., in whose reign England may be said to have first possessed a regular and permanent navy. Before his reign our sovereigns had but few ships; and when they wished to transport an army to France, or to undertake any considerable naval enterprise, it was usually effected by requisitions of ships and seamen from the different seaport towns of the kingdom, or by hiring them from the merchants of Hamburg, Lubek, Genoa, &c.; to be dismissed as soon as the occasion for their service was over. But Henry, whose naval force, as in the preceding reigns, was chiefly dependent on foreign auxiliaries, caused several 'shippes royall' to be constructed for the service of the state; among which were the 'Regent,' the 'Marie Rose,' and the celebrated 'Henri Grâce de Dieu,' of 72 guns, 700 men, and about 1,000 tons burthen. At the end of his reign in Jan. 1547, the verified list of the navy amounted to seventy-one ships and vessels of all sorts, measuring 11,268 tons. During the succeeding reign of Edward VI. and Mary, the naval force of England diminished considerably, and at the demise of the latter in 1558 amounted only to twenty-six vessels, measuring 7,110 tons burthen. During the long and prosperous reign of Elizabeth which ensued, the navy was greatly encouraged. The naval force collected to oppose the Armada, which consisted of 160 ships with nearly 30,000 men, amounted to 176 sail equipped with about 15,000 men; of these, thirty-four ships with 6,225 men, a larger royal armament than had ever before assembled together, belonged to the crown, the remainder being made up from London, Bristol, Yarmouth, the Cinque Ports, &c. During the last twenty-five years of Elizabeth's reign the navy almost doubled its number; and at her death, in 1603, it amounted to forty-two ships, measuring 17,055 tons, and carrying 8,346 seamen. The reign of James I. was remarkable for the first able and scientific naval architect, Phineas Pett, to whom the art of shipbuilding was indebted for many improvements, particularly in the diminution of top-hamper. 'In my own time,' says Raleigh, 'the shape of our English ships hath been greatly bettered; in extremity we carry our ordnance better than we were wont; we have added crosse-pillars in our royall shippes to strengthen them; we have given longer floares to our shippes than in olden times, and better bearing under water.' The striking of topmasts was also invented in this reign; and besides the improved shape of the vessels,

NAVY

Raleigh mentions various minor improvements, adding, 'to the courses we have devised studdingsails, spritsails, and topsails; the weighing of the capstan is also new, and the chain-pump and bonnet; we have fallen into consideration of the length of cables, and by it we resist the malice of the greatest winds that can blow.' At the death of James I. in 1625, the royal navy consisted of thirty-three ships, measuring 19,400 tons. The navy was first divided into rates and classes under Charles I., who built several new ships in the beginning of his reign, and among others the 'Sovereign of the Seas,' a larger ship than had ever been built in England, carrying 100 guns, and measuring 1,637 tons. But in 1648 Prince Rupert carried off twenty-five ships, none of which ever returned to England; and so reduced was the navy at the commencement of Cromwell's government, that he could muster only fourteen men-of-war, some of them carrying only forty guns. But his vigorous administration speedily raised the navy to a magnitude and power formerly unknown; and under the command of Blake, it became not merely equal but superior to that of the Dutch, then the greatest maritime power of Europe. It was during the Protectorate that the ratings into which Charles I. had first divided the navy were clearly defined, and a regular system established, which has, with little alteration, remained in force down to the present time. At the death of Cromwell in 1658, the navy amounted to 157 ships, measuring 21,910 tons, and carrying 50,000 men.

At the restoration of Charles II. in 1660 (from which is dated the third period of British naval history), the whole fleet amounted to only sixty-five ships; but under the able administration of the duke of York, the royal fleet soon became a fine armament; and though the retirement of the latter (in consequence of his inability to take the Test Act), and the subsequent extravagance of the king, caused the navy to decay, yet such prompt and effective measures were afterwards taken by the duke, on his recall to office, for its restoration, that at the demise of Charles II. the navy amounted to 179 vessels, measuring 103,558 tons. During the foregoing reign, a remarkable change had taken place in scientific and mechanical operations, and the art of ship-building, so long practised on vague and imperfect principles, began to be more highly and extensively developed; for not only were the proportions and qualities of vessels improved, but the mind of the designer was directed to theoretical investigation; and thus the beginning of the third period of naval history marks the first application of science to naval architecture. It must, however, be remembered, that the science thus applied was essentially deductive. On his accession to the throne, James II. continued to evince the same warm interest which, as lord high admiral, he had always manifested for the welfare of the navy. He suspended the navy board, and appointed a new commission, with which he

joined Sir Anthony Deane, the best naval architect of the time: four hundred thousand pounds were annually set apart for naval purposes; and so diligent were the commissioners in the discharge of their duty, that on the abdication of James, in 1688, the navy amounted to 173 sail, measuring 101,892 tons, and carrying 6,930 guns and 42,003 men. Under the administration of William and Mary, who made little alteration in the system adopted by their predecessor, 99 new ships were added to the fleet; and the celebrated engagement off Cape la Hogue, in 1692, gave the British navy its ascendancy over that of France. Queen Anne at her accession found the navy to consist of 272 vessels, measuring 159,020 tons; but in the third year of her reign a most destructive storm visited this country and the adjacent coasts, by which the navy sustained great damage and loss. No fewer than ten men-of-war were totally lost, and many more were driven on shore and damaged. All measures adding to the strength and efficiency of the navy were exceedingly popular during this reign, and every plan compatible with financial economy was adopted for its benefit; so that though the number of ships was less at the end of Anne's reign, 1714, than at its commencement, the tonnage had increased 8,199 tons. During the first four years of George I. large sums were voted for the extraordinary repairs which were required after the long war. A general survey was made of the dockyards and sea-stores; new dimensions for several classes of ships were established; and at the death of this monarch, in 1727, the navy consisted of 233 ships, measuring 170,862 tons. The navy remained stationary for the first twelve years of the reign of George II.; but on hostilities breaking out with Spain, in 1739, it was considerably augmented, and a scale of increased dimensions was established in 1742. In the wars of 1744 and 1755, our naval enterprises were crowned with signal success; and at the demise of George II., in 1760, the navy consisted of 412 ships, measuring 321,104 tons, the vote for the naval service of that year being 5,611,508*l.*, 51,645 seamen, and 18,355 marines. The unprecedented progress of the navy during the long reign of George III. is familiar to all. It may be sufficient, therefore, to observe, that though the combined fleets of France and Spain appeared to have an ascendancy during the American war, the victories of Rodney restored British superiority. The nature of the struggle with revolutionary France, the bitterness with which it was carried on, and the fleets required not merely for the protection of our own shores, but for that of our mercantile shipping and of our numerous colonies in all parts of the world, led to an immense increase of our naval force; and while our navy was thus progressively augmented, the decisive victory of the 1st of June, 1794, followed by those of St. Vincent, Camperdown, the Nile, Copenhagen, and Trafalgar, almost destroyed every fleet

NAVY

that could be opposed to it, leaving us undisputed masters of the ocean.

From the commencement of hostilities in 1793 to the peace in 1815, the British captured from their enemies 155 ships of the line, and 586 smaller war vessels, while they lost (otherwise than by natural causes) 5 ships of the line and 151 smaller vessels of war.

Since the peace great reduction has been made in the number of royal ships, but the size of the individual vessels has been vastly augmented, the aggregate tonnage being now far in excess of that of 1815. The navy during this period has undergone three distinct reconstructions: first, by the substitution of larger ships; secondly, by the adoption of steam; and thirdly, by replacing wooden ships in a great degree by armour-plated vessels, almost invulnerable to shot, many of which have the peculiarity of reviving the ancient mode of warfare by being used as *rams*, the massive iron prows and powerful screw propellers constituting, however, a sensible difference from the beaked galleys of the ancients. Simultaneously the guns of the ships have been decreased in number, but enormously increased in power and range. On the whole, the power of a ship of war has so augmented within the last half-century, that it is probable that a heavy-armed iron-clad steam sloop of the present day could destroy a fleet of first-rates of the class known to Nelson, without receiving appreciable damage in return. To show how deceptive an estimate of the navy's force would be formed from a mere numerical return, the following statement of the progressive increase of the tonnage of ships of the most powerful class is alone necessary: In 1677 the largest vessel did not reach 1,600 tons; 1,800 tons had been attained in 1720; 2,000 tons by 1745; by the end of the American war there was a ship of 2,200 tons. In 1800, 2,500 tons was reached. Before the French war closed, there was a ship of 2,616 tons. For the Russian war we had a vessel of 4,000 tons; and now the largest iron-side—only a frigate, and carrying but 26 gigantic guns—counts 6,321 tons!

There is yet a moot question with regard to armour-plated ships themselves, which may perhaps in its ultimate results lead to further alteration. The great increase in the weight of artillery (the largest guns being now of the weight of 12 tons, exclusive of carriage) has led to the question whether it is practicable for a vessel to carry them as a broadside armament without unduly straining the keel and floors. Naval architects consider that ships, as now built, cannot; and, if they could, the management of such ponderous guns would be a matter of great difficulty. On the other hand, a ship can readily carry these or even heavier cannon amidships, as swivels. But as the protection of armour is now necessary, these swivels require shot-proof covering, for which purpose Captain Cowper Coles, R.N., has invented revolving iron turrets, centred on the keel, and made to revolve by machinery con-

nected with the ship's engines. The bulwarks are made to fall down on hinges, and the masts are based on three diverging supports. These arrangements give t-

range; and, viewed as a battery, there can be no question as to the advantage of the system. The Americans constructed, during the war of secession, numerous vessels on this plan; but they have not proved good sea-boats. The 'Royal Sovereign,' on the contrary, which was adapted in this country to Captain Coles' design, has held her own against the best of the other iron-clads in heavy sea-ways. The Admiralty still debate whether to try to make broadside-armoured vessels, which are known to be seaworthy, capable of carrying the heaviest ordnance, or to build seaworthy turret-vessels which can without doubt carry guns of the largest calibre.

It is a noteworthy circumstance, that of the new iron vessels, many of the finest have been built in private yards on the Thames, Tyne, Mersey, and Clyde.

The following table will show the force of the British navy at four distinct periods memorable in naval history:—

The present constitution of the navy so often excites political and professional discussion, that a greater detail is desirable. The following table shows the strength of the several classes of vessels composing the steam navy in 1865. For purposes of offensive war, these may be taken to represent our total effective force; for the wooden sailing vessels of the old type (of which many still exist), although useful as dépôts, hulks, and training-ships, would be of little avail in line of battle, supposing that they could ever get there.

The Steam Navy of Great Britain, 1865.

3 An approximation.

653

NAVY

These classes of the royal fleet are thus subdivided:—1. *Rated ships*. *First rates*: ships carrying 110 guns and upwards, or having complements of at least 1,000 men. *Second rates*: one of the royal yachts, and all ships carrying from 81 to 109 guns, or having complements of from 800 to 999 men. *Third rates*: other royal yachts; all ships bearing the flag or pendant of an admiral superintendent or a captain superintendent of a dockyard; ships carrying 60 to 80 guns, or having complements of from 601 to 799 men. *Fourth rates*: frigate-built ships carrying from 410 to 600 men. *Fifth rates*: ships the complements of which are not more than 400 and not less than 300 men. *Sixth rates*: other ships bearing captains. The second class (sloops) includes all vessels placed in the charge of commanders, and carrying their principal armaments on one deck in broadside ports. The third class (gun vessels) comprises all vessels under commanders, and carrying their principal armament on one deck amidships. The fourth class, principally devoted to gunboats, is sufficiently described above.

Government of the Navy.—The general direction and control of all affairs connected with the navy is intrusted, under her majesty, to the lord high admiral, or to the commissioners for discharging the functions of that officer. The duties of the lord high admiral were formerly judicial as well as administrative; he having not merely to govern the navy, but to preside over a court for adjudging all nautical cases, and for taking cognisance of all offences committed on the high seas. But the judicial are now separated from the other duties of this high functionary, being devolved upon the judge of the Admiralty Court. [ADMIRALTY, COURT OF.]

From the reign of Queen Anne down to the present time, with the exception of the short period during which William IV., when duke of Clarence, held the office, the duties of the lord high admiral have been discharged by commissioners. These have consisted generally of a first lord and of four junior lords. Civilians may be appointed to these offices; but at least two of the lords are professional men. But though assisted by the advice of junior lords, practically all the power and authority of the board is vested in the first lord. The powers exercised by the Board of Admiralty are very extensive and important. They have the absolute control of the matériel and personnel of the navy, both as regards discipline and finance; subject, of course, to the votes of parliament and the annual Mutiny Act. The navy is represented in parliament by the first lord, who is a cabinet minister, by one civil lord and one of its secretaries, who are members of the government, and by any of the naval lords who may happen to be in the House.

Under the superintendence of the lords commissioners, the civil departments of the Admiralty are directed by a controller of the navy, an accountant-general, a storekeeper-

general, a controller of victualling, a director-general of the medical department, a director of transports, a director of engineering and architectural works, an hydrographer, and a controller-general of the coastguard.

Passing to the active service, there are three gradations of admirals, viz. admirals, vice-admirals, and rear-admirals; distinguished by the mast at which they severally carry the St. George's flag, viz. at the main for an admiral, fore for a vice-admiral, and mizzen for a rear-admiral. All admirals, whatever be their rank, take the common title of *flag officers*. Admirals rank with generals in the army, vice-admirals with lieutenant-generals, and rear-admirals with major-generals.

The command of every rated ship is intrusted to a captain, who has under him a commander (if the ship be of the first, second, or third rate), a certain number of lieutenants, according to the size of the ship, with a master, paymaster, marine officers, surgeons, sub-lieutenants, engineers, midshipmen, gunners, &c. A captain of three years' standing ranks with a colonel in the army, and a captain of less than three years' standing, or a commander, with a lieutenant-colonel; a lieutenant of eight years' standing ranks with a major, and other lieutenants with captains; sub-lieutenants with lieutenants in the army, and midshipmen with ensigns. The captain is responsible for the discipline and efficiency of the crew, and the good order of the ship. But although he is furnished with minute instructions for his guidance in every particular, much must always necessarily depend on his conduct and character. He has power to order punishment to be inflicted; but his sentence must be carried out in the presence of all the officers and the ship's company. An account, stating all the circumstances, must also be entered in the ship's log, an abstract of which is forwarded each quarter to the Admiralty. This regulation has tended to repress hasty and inconsiderate punishment; and has done much to improve the conduct of the officers, as well as to promote the proper discipline of the navy.

Composition of the Navy.—The navy is composed of two bodies of men—sailors and marines [MARINES]; and the officers under whose command it is placed are divided into three classes, viz. commissioned, warrant, and petty officers. Commissioned officers comprise flag officers, commodores (who are acting flag officers), captains, commanders, lieutenants, staff commanders, masters, inspectors of machinery, chief engineers, sub-lieutenants, second masters, chaplains, naval instructors, medical officers, paymasters, secretaries to flag officers, assistant paymasters, and all officers of marines. Warrant officers are those who hold their appointment by warrant from the lords commissioners of the Admiralty; to this class belong gunners, boatswains, carpenters, and engineers. Petty officers are divided into three classes: chief, first class, and second class. It is unnecessary to specify the numerous com-

ponents of these classes, who comprise all the skilled artificers of the crew.

Any person may enter the navy as a common seaman, on application to the commanding officer of any of her majesty's ships in commission, provided he be approved by the examining surgeon, and have not previously been 'discharged from the service with disgrace.' Persons who have never been at sea are rated as ordinary seamen of the second class, and seafaring men are rated as *ordinary* or *able* seamen, according to their experience. [IMPRESSION.]

Young gentlemen enter the service as naval cadets between twelve and fourteen. The cadet must remain in the training ship a twelve-month; he is then discharged into a sea-going ship as a cadet, unless he obtain a first-class certificate on passing out, in which case he will be discharged as a midshipman. If discharged as a cadet, he has to serve another twelve-month in order to qualify for a midshipman. After serving as midshipman three years and a half, he is examined (provided he is nineteen years of age) in seamanship, and he then obtains the rank of acting sub-lieutenant, which rank is confirmed on his passing the examinations at the Naval College at Portsmouth.

No person is eligible for promotion to the rank of lieutenant till he has passed the above three examinations; but if a midshipman has passed in seamanship he may, by death or invaliding vacancy, be granted a commission as *acting* lieutenant, which is generally confirmed on his passing the final examination at Portsmouth.

Captains and admirals are promoted by seniority, on what is termed a *flag promotion* taking place; but a captain must have served as under, in command of a rated ship, before he can obtain his flag; viz.

In war	4 years.
In war and peace combined	5 "
In peace	6 "

All other classes of officers are promoted at the discretion of the Board of Admiralty, the patronage resting with the first lord. There is, however, an educational standard to which every officer must attain, prior to promotion or advancement. For other particulars relating to the navy, see NAVAL ARCHITECTURE, SHIP, and the other naval articles, which will be found under their respective heads in this work.

Foreign Navies.—Space forbids any lengthened description of foreign navies, and it must suffice to state that the marine of nearly every power has advanced greatly in efficiency during the past few years. There seems to be a contest between the powers which shall form the best fleet of iron-sided vessels. Nations little known in modern naval warfare are already acquiring these terrible floating fortresses. Italy, Turkey, Egypt, Sweden, Denmark, Spain, and Portugal have already several; while France, Russia, and the United

States have fleets which the British government might not always find it easy to match. It is fair to add, that a large proportion of these foreign armour-plated vessels, as of those built for the British navy, have been constructed in the workshops of the Thames, Clyde, Mersey, and Tyne.

Nazarene. A native of Nazareth. This name is commonly applied in the East to Christians, as being the followers of Jesus of Nazareth. It also denotes a sect which sprang up in Palestine in the second century, and endeavoured to engraft the rites and observances of the Jews on the religion of Jesus Christ: in this respect they bore a considerable resemblance to the Ebionites, whose contemporaries they were, but with whom they must not be confounded. No traces of them existed in the fifth century.

Nazarite (Heb. *nazar, to separate*). In the Levitical law, one separated to the Lord by a vow. (Num. vi.) The chief observances of the Nazarites were, to refrain from drinking wine, to suffer the hair to grow, and to avoid coming in contact with a corpse.

No Great Regno (Lat.). In Law, a writ to detain a person from going out of the kingdom without the king's license, directed to the sheriff, or to the party himself. The use of the writ is to prevent a party from withdrawing his person and property from the jurisdiction of the courts in England; but this purpose was served at common law before the late Insolvent Act by arrest, and bail obtained. This writ lies, therefore, where there is a suit in equity for a demand for which the plaintiff could not arrest at law; and is always granted upon a bill just filed in equity.

Neap or Weep Tides. The lowest tides, being those which are produced when the attractions of the sun and moon on the waters of the ocean are exerted in directions perpendicular to each other. When the two forces act in the same or in exactly opposite directions, the *spring* or highest tides are produced. The neap tides take place about four or five days before the new and full moons. [TIDES.]

Neat (A.-Sax. *nyten*, from *nitan* = *ne witan*, *not to know*; corresponding to the Greek *ἄλογον*, as a name for an irrational animal: Wedgwood). A term applied to cattle: *neat's foot oil* is the fat obtained by boiling calves' feet.

Nebulæ (Lat. *clouds* or *mists*). In Astronomy, the name given, on account of their general cloudy appearance, to a very numerous class of celestial objects, being, however, for the most part, *telescopic*, and only visible in telescopes of considerable power.

It is to Sir William Herschel that astronomy is indebted for the first examination and analysis of these remarkable objects. A few of them have indeed been known since the discovery of the telescope, and one or two of them are visible to the naked eye; but his powerful telescopes first disclosed the fact of their existence in immense numbers, and in all quarters of the heavens, not indeed distri-

NEBULÆ

buted uniformly, but generally speaking with a marked preference to a broad zone, crossing the Milky Way nearly at right angles, its general direction being not very remote from that of the hour circle of 0h. and 12h. In the southern hemisphere the distribution appears to be more uniform.

Nebulæ are divided by Sir W. Herschel into the following classes: 1. Clusters of stars, in which the stars are clearly distinguishable; 2. Resolvable nebulæ, or such as excite a suspicion that they consist of stars, and which any increase of the optical power of the telescope might be expected to resolve into distinct stars; 3. Nebulæ, properly so called, in which there is no appearance whatever of stars; 4. Planetary nebulæ; 5. Stellar nebulæ; and 6. Nebulous stars.

Clusters of Stars.—These are either globular or of an irregular figure, forming bright isolated patches, which attract attention, as if they were brought together by some general cause. The Pleiades is a cluster of this sort: the naked eye can distinctly perceive six or seven stars in it, and may catch occasional glimpses of a great many more; but the telescope shows fifty or sixty crowded together in a very moderate space, and insulated from the rest of the heavens. A luminous spot, called *Præsepe*, or the Beehive, in the constellation Cancer, is resolved entirely into stars by an ordinary telescope. In the sword-handle of Perseus is another such spot, crowded with stars, but not so easily resolved. There are a great number of less distinct nebulous specks of the same kind, which in ordinary telescopes have much the appearance of comets without tails, and have frequently been mistaken for such: when, however, they are examined with instruments of great power, any such idea is completely destroyed. They are then, for the most part, perceived to consist entirely of stars, crowded together so as to occupy almost a definite outline, and to run up to a blaze of light in the centre, where their condensation is usually the greatest. Many of them are of an exactly round figure. Others, again, are of an irregular form, and less definite in their outline, so that it is not easy to say where they terminate. In some of them the stars are nearly all of a size, in others extremely different; and it is no uncommon thing to find a very red star occupying a conspicuous situation in the group.

Resolvable nebula are considered as objects of the same nature as the preceding; but as being either too remote, or consisting of stars too faint, to affect us by their individual light. They are almost universally round or oval; their irregularities of form being extinguished by the distance, and only the general figure of the condensed parts being discernible. In telescopes of insufficient optical power, all the great globular clusters exhibit themselves under this appearance.

Nebula, properly so called.—Observations with superior telescopes had rendered it probable that no physical distinction existed

between this class of objects and clusters of stars, the difference of appearance seeming to depend only on the power of the telescope with which they were observed; but recent researches with the spectroscope applied to the telescope have completely negatived such an hypothesis. Although multitudes of nebulæ which in Herschel's eighteen-inch reflector exhibited not the slightest appearance of resolvability, when examined with Lord Rosse's six-foot reflector are clearly resolvable, and seem to consist merely of clustering stars, still many exist which, under the greatest powers which have been yet applied, show no signs of being composed of separate stars. The great nebula in the sword-handle of Orion, discovered by Huygens in 1666, and repeatedly figured and described by astronomers since that time, is a notable instance. Another in the constellation of Andromeda may be mentioned, which is visible to the naked eye, and often mistaken for a comet. Its appearance is described by Simon Marius as that of a candle shining through horn. Its form is a pretty long oval, increasing by insensible gradations of brightness, at first very gradually, but at last more rapidly, up to a central point, which, though very much brighter than the rest, is yet evidently not stellar, but only nebulous matter in a high state of condensation. It has in it a few small stars; but they are obviously casual. Mr. G. P. Bond describes it as extending nearly two and a half degrees in length, and upwards of a degree in breadth. Like the last described, a very numerous class of nebulæ are of a round or oval figure, increasing more or less in density towards the central point. In this respect, however, they differ extremely; in some the condensation being slight and gradual, in others great and sudden. They also present great diversity of appearance, in respect of deviation from the spherical form. Some are only slightly elliptic, others much extended in length; and in some the extension is so great as to give the nebula the character of a long, narrow, spindle-shaped ray, tapering away at both ends to points. Some nebulæ are annular; but these are among the rarest objects in the heavens. The most conspicuous is situated halfway between the stars β and γ Lyrae, and may be seen with a telescope of moderate power.

Planetary nebula have exactly the appearance of planets—round or slightly oval discs, in some instances quite sharply terminated, in others a little hazy at the borders, and of a light exactly equable, or only a little mottled, which, in some of them, approaches in vividness to that of actual planets. Whatever the nature of these objects may be, they must be of enormous magnitude. One in Aquarius presents the diameter of 20"; another, in Andromeda, has a visible disc of 12", perfectly defined and round. Granting them to be equally distant from us with the stars, their real dimensions must be such as would fill, on the lowest computation, the whole orbit of Uranus. Their intrinsic splendour must also be immeasurably

inferior to that of the sun's: for a circular portion of the sun's disc, subtending an angle of 20", would give a light equal to 100 *full moons*, whereas not one of the nebulae in question is discernible with the naked eye. Lord Rosse has recently observed a marked spiral arrangement in several nebulae.

Stellar nebulae are those in which the condensation of the nebulous matter towards the centre is great and sudden; so sudden, indeed, as to present the appearance of a dull and blotted star, or a star with a slight burr round it. The *nebulous stars* present the beautiful and striking phenomenon of a sharp and brilliant star, surrounded by a perfectly circular disc or atmosphere of faint light: in some cases dying away on all sides by insensible gradations, in others almost suddenly terminated. A very fine example of such a star is 55 Andromedæ, R.A. 1h. 43m., N.P.D. 50° 7'.

'The nebulae,' says Sir J. Herschel, 'furnish, in every point of view, an inexhaustible field of speculation and conjecture. That by far the largest of them consist of stars, there can be little doubt; and in the interminable range of system upon system, and firmament upon firmament, which we thus catch a glimpse of, the imagination is bewildered and lost. On the other hand, if it be true, as, to say the least, it seems extremely probable, that a phosphorescent or self-luminous matter also exists, disseminated through extensive regions of space, in the manner of a cloud or fog, now assuming capricious shapes, like actual clouds drifted by the wind, and now concentrating itself like a cometic atmosphere around particular stars, what, we naturally ask, is the nature and distinction of this nebulous matter? Is it absorbed by the stars in whose neighbourhood it is found, to furnish, by its condensation, their supply of light and heat? or is it progressively concentrating itself, by the effect of its own gravity, into masses, and so laying the foundations of new sidereal systems, or insulated stars? It is easier to propound such questions than to offer any probable reply to them.' ('Treatise on Astronomy,' *Cabinet Cyclopædia*. See also Herschel's *Outlines of Astronomy*.)

The recent researches of Mr. Huggins have proved that many of the unresolvable nebulae consist, chiefly at least, of glowing gaseous matter; nitrogen and hydrogen being apparently their principal constituents. This highly important discovery entirely alters the ideas previously entertained respecting the nature of such nebulae. The opinions which have been entertained of the enormous distances of the nebulae, founded upon the supposed remoteness at which stars would cease to be separately visible in our telescopes, must now be abandoned, in reference at least to those of the nebulae which have thus been proved to be gaseous. If we suppose the gaseous substance of these objects to represent the *nebulous fluid* out of which, according to Herschel's hypothesis, stars are to be elaborated by subsidence

and condensation, we should expect a gaseous spectrum with groups of bright lines as numerous as the dark lines, due to absorption, found in the spectra of the stars. We cannot, however, conceive that the elementary gases composing these nebulae can ever condense into solids and liquids such as we find in our own solar system.

Necessity, Doctrine of. That scheme which represents all human actions and feelings as links in a chain of causation, determined by laws in every respect analogous to those by which the physical universe is governed. This doctrine has been attacked and defended with great zeal, in almost every period of speculative enquiry since the Reformation. The inductive method of research, applied by Bacon and his contemporaries to the phenomena of nature, led very soon to the adoption of a similar method in reference to the phenomena of mind. The discovery, or rather the distinct reassertion, of the law of association, by Hobbes, and the ready solution which it appeared to furnish of states of consciousness, which, without it, would have seemed capricious and unaccountable, encouraged many philosophers to attempt its application to every province of the human mind. It is only in connection with this fact that the prevalence of necessarian views in modern times can be adequately explained. The distinction between man and nature, between the actions of a self-conscious agent and the workings of blind unintelligent powers, was considered by the great philosophers of antiquity as the groundwork of their systems of morality, and as involved in the very conception of moral science. It was natural that this distinction should be felt to be a barrier to the progress of an exclusively empirical psychology. To the historians of man's nature the necessity of his actions appeared in the light of an hypothesis which lay at the very foundation of their enquiries, precisely as the natural philosopher is compelled to assume the regular recurrence of the same outward phenomena under the same circumstances. The psychologist considers the states of which he is conscious merely as they are related to each other in time; and, thus considered, it seems to him a mere identical proposition to assert that all that can be known of them is the order of their succession. If their succession were arbitrary or uncertain, nothing could be known of it, and the science which he professes could no longer have an existence. It is in this consideration, rather than in the dialectic subtleties by which the doctrine has been sometimes defended, that the real strength of the necessarian lies. So long as he can maintain the merely phenomenal character of human knowledge, he can reduce his opponents to the dilemma of either denying the possibility of mental science altogether, or of admitting the existence of those uniform laws which are its only object. In its relation to morality, the doctrine of necessity has been considered to involve dangerous consequences. Attempts have been made by modern neces-

NECK OF A CAPITAL

arians to rescue it from this imputation. Sir James Mackintosh, in particular, has devoted some portion of his Dissertation (*Encyclopædia Britannica*) to the explanation of the principal ethical terms, on the necessarian hypothesis. (*General Remarks*, sec. vii. p. 393.) Notwithstanding the ingenuity of this effort, the student will probably find, on careful examination, that the great question at issue is left much in the same state as before.

Neck of a Capital. In Architecture, the space above the shaft of a column, between the annulet of the capital above, and the astragal at the top of the shaft below. In Mediæval Architecture, the mouldings at the bottom of the capital of a column are frequently called the neck mouldings.

Necrology (Gr. νεκρός, *dead*, and λόγος). A collection of biographical notices of deceased persons, published shortly after their death, is commonly called a necrology. The list of deceased benefactors to a monastery, cathedral, &c., was also termed its necrology.

Necromancy (Gr. νεκρομαντεία). Divination by consulting the spirits of the dead. The Necyomanteia of the *Odyssey* exhibits the superstition in a very peculiar form. Odysseus (Ulysses) performs a sacrifice with peculiar solemnities, and pours the sacrificial blood into a ditch; the spectres of the dead rush wildly from the infernal regions to taste the blood; when, discovering the shade of Teiresias, of which he was in search, he compels it to answer his questions. The rest of the book, in which Odysseus appears actually to descend to the shades, and to see the punishments of celebrated criminals, is suspected by some commentators to have been an interpolation of later times. Similar customs in practising the art of necromancy seem to have been followed for a long period in Greece and Italy. Horace mentions the pouring of the blood of a sacrificed sheep into a ditch in order to attract the Manes from beneath. But in Thessaly, the most celebrated of classical regions for its proficiency in the art of magic, peculiar horrors seem to have attended the exercise of necromancy. Erichtho, Lucan's Thessalian witch, reanimates the corpse of a soldier slain in battle, and compels him to answer her questions respecting futurity. But the ψυχαγωγοί, or professed evokers of spirits, in Thessaly, seem to have performed their rites, whether as impostors or as fanatics, with the sacrifices of human beings and various other enormities. [MAGIC; WITCH.]

Necronite. A variety of Orthoclase. It is found in small nodules in the limestone of Baltimore, and when struck it exhales a fetid odour resembling that of putrid flesh.

Necrophagans (Gr. νεκρός, and φάγω, *I eat*). The name of a family of Clavicorn beetles, comprehending those which feed on dead and decomposing animal substances.

Necropolis. Literally, a *city of the dead*, or a common graveyard for interring the bodies of deceased persons. The burying-places of the ancient Egyptians were often divided into

NEGATIVE SIGN

places of interment for the separate castes in the same enclosure. One of the most singular of these structures may be seen at Isu-el-Haghar in Lower Egypt: it is a parallelogram of 2,160 French feet on the side, by 1,440 feet, and contains several rows of tombs. Amongst the Greeks, the custom appears to have prevailed of using the ancient quarries for this purpose, as at Nauplia, and near many cities of Asia Minor also. The necropolis of the Greek cities was always removed from the habitations of the living; and no one was buried in the cities, but as an exception. For the Etruscan tombs, see Dennis, *Cities and Cemeteries of Etruria*.

Necrosis (Gr. νέκρωσις). In Botany, a disease of plants, chiefly found upon the leaves and soft parenchymatous parts of vegetables. It consists of small black spots, below which the substance of the plant decays; and hence is commonly called *spotting*.

Necrosis. This term is applied in Surgery to the mortification of parts of bones.

Nectar (Gr.). In Greek Mythology, the drink of the immortal gods. [AMBROSIA.]

Nectarine. A variety of the peach, in which the velvety covering of the skin is obliterated, and the surface is smooth and shining. Nectarines are generally more highly flavoured than peaches.

Nectarium. In Botany, the nectary of a flower, that is to say, any part that secretes a honey-like substance. The term is variously applied to modifications of the petals, of the stamens, and of the disc.

Needle Ore (so called from the acicular form of its crystals). A native sulphide of bismuth, copper and lead, found at Beresowsk in Siberia, embedded in white Quartz. It occurs in acicular four or six sided prisms.

Needle Stone. The name given to acicular varieties of Natrolite and Scolecite.

Negative (from Lat. nego, *I deny*). In Logic, this term denotes the quality of a proposition which denies the agreement between the subject and predicate.

Negative Sign. In Algebra, this term denotes an operative symbol written thus, —: it is also called *minus*, and combines with other symbols according to predetermined rules. The fundamental operative laws of algebra remaining the same, the results will bear different interpretations, or admit of no intelligible interpretation whatever, according to the greater or less generality of the meanings ascribed to the symbols. Thus in the first generalisation of ordinary arithmetic, where letters are used as symbols of numbers, the negative sign denotes subtraction, and a result $a - b$ is perfectly intelligible so long as a exceeds b , but simply unintelligible when b exceeds a . In the latter case, of which $3 - 5$ may serve as an illustration, the general laws of algebra permit us to write the result in any one of the forms $(5 - 2) - 5$, $5 - 5 - 2$, $0 - 2$, -2 ; in which last form the result in question is called a *negative number*. When, more generally, we operate

upon symbols of quantity, a result such as — *a* is called a *negative quantity*, and may always be considered as a quantity of the same *nature* as *a*, but diametrically opposite in *kind*; thus if *a* represent distance measured *northwards*, — *a* will denote the same distance measured *southwards*; if *a* denoted a sum of money *gained*, — *a* would denote an equal amount *lost*; or again, if *a* represented *future* time, — *a* would denote *past* time, and so on.

The doctrine of negative quantities involves many metaphysical subtleties, and has given rise to numerous discussions; amongst the most instructive works on the subject are the following: Carnot's *Géométrie de Position*, Paris 1803; Peacock's *Algebra*, Cambridge 1830, and his 'Report on certain Branches of Analysis,' *Proceedings of the British Association* 1834; De Morgan's *Trigonometry*, London 1849, and his art. in the *Penny Cyclopædia*; Sir W. R. Hamilton's *Lectures on Quaternions*, Dublin 1853, and his 'Essay on Conjugate Functions, &c.' in *Transactions of the Royal Irish Academy* 1835.

Negotiable Instruments. In Law, instruments on which the right of action passes by mere assignment, signified ordinarily by indorsements, of which the chief are bills of exchange and promissory notes. To render them legally negotiable, it appears that the words *payable to bearer or to order*, or equivalents for these, must be employed.

Negro (Span.; Lat. *niger, black*). This term has been applied to the dark races of men distributed over the tropical and southern districts of Africa, and found also in the Papuan, Australian, and Tasmanian islands. Latham has defined a negro as an intertropical African in 'a humid alluvial locality.' The skulls of negroes exhibit a more or less prognathism or protrusion of the maxillary alveoli, and diagonal position of the teeth. The hair is crisp and woolly, and the calf of the leg fleshless; the feet are large and flat, whilst the pelvis is contracted. The outer surface of the brain of negroes exhibits a more symmetrical arrangement of the gyri than is usual in Europeans; it is not known whether this difference extends to the internal cerebral structure. The large size of the true molar teeth and the junction of the frontal and squamosal bones are also frequent characters of the negro races.

The distinctions of this race are marked and peculiar; but they are not universal or everywhere the same. Thus, the colour varies, although less so, perhaps, than that of any other of the great varieties of mankind; the Hottentots, and various southern tribes belonging to the Ethiopian race, are in this and other respects widely different from their brethren. The woolly hair, dark jet colour, and some external peculiarities of conformation, seem chiefly to belong to those numerous tribes which inhabit the west coast of Africa, between the equator and the tropic of Cancer. But, even within that region, some tribes are to be found whose physiognomy is very different

from that which we are accustomed to regard as representing the negro type. South of the equator many of the tribes are inferior in strength and stature, and very different in appearance: from this region many of the Brazilian negroes are imported. In New Guinea, off the south-eastern extremity of Asia, a native population is found with most of the characteristics of the African negro.

The negro race appears to have been subjected to the tribute of furnishing slaves to its more powerful and intelligent neighbours from a very remote period. Many ages before the first European slave ship had visited the coasts of Africa, the Arabs bore off slaves in their caravans, across the Sahara, to the northern coasts of the continent; and even in classical writers (Terence, for example) we find mention made of black or Ethiopian slaves. [SLAVE TRADE.]

By the mixture of the negro and white races the mulatto is produced; the Zambo is the offspring of a negro and an American Indian. The numerous varieties of these mixed races, according to the proportion of negro, European, or Indian blood in each, are classed and denominated accurately in the West Indies. It may probably be estimated that there are now on the continent and islands of America, including negroes and mulattoes, but excluding those mixed races which have a larger proportion of European blood, about ten million individuals of African descent; viz.

In the United States . . .	3,500,000
British colonies . . .	900,000
Hayti . . .	700,000
Spanish, French, &c. West Indies . . .	1,200,000
Brazil . . .	2,500,000
The free states of continental America, formerly Spanish colonies . . .	1,000,000
	<hr/> 9,800,000

Of these many are still in a state of slavery; the remainder, except in Hayti, forming an inferior and generally an oppressed class of free inhabitants. The ultimate destiny of this multitude of human beings is a matter of anxious speculation. Hayti, peopled by the slaves of the French colony of St. Domingo, who threw off the yoke at the period of the French revolution, is the only region in which they have as yet established an independent community; and the progress of that community in civilisation is not such as to raise the hopes of the philanthropist.

The existence of the distinguishing features of the negro race in a strongly marked degree is uniformly associated with the lowest state of barbarism; and as they recede from this strongly marked type, we find a greater degree of civilisation and improvement. The inevitable conclusion is, that every variety of the negro type, which comprises the inhabitants of almost all Central Africa, is indicative of mental inferiority; and that ferocity and stupidity are

NEGUNDO

the characteristics of those tribes in which the peculiar negro features are found most developed.

But without drawing any conclusions as to their inferiority merely from their configuration and appearance, it may be remarked that while most of the European and Asiatic nations have attained to a high state of civilisation, they continue, with few exceptions, in nearly primeval barbarism. It is scarcely enough to reply that this is the result of the unfavourable circumstances under which they have been placed. An intelligent enterprising people will contend against unfavourable circumstances, and make them become favourable; but the Africans, with the questionable exception of the ancient inhabitants of the valley of the Nile, have never displayed any considerable degree of enterprise or invention.

For an able summary of the physical and mental characters, as well as the history of the negro races, see Campbell's *Negronia*, 8vo. Philadelphia 1855; Pruner Bey's *Mémoire sur les Nègres*, 8vo. Paris 1861.

Negundo. A genus of *Aceraceæ* comprising an ornamental hardy tree of small stature, sometimes introduced with good effect into shrubberies. A variegated-leaved variety, in which the leaves are very conspicuously marked with white, is one of the most attractive of deciduous trees, if well placed in planting. The only species is called *N. fraxinifolium*.

Nehalonia. The name of an ancient Dutch and Flemish divinity who presided over commerce and navigation. Her origin and general character are unknown, and even the name suggests only forced and unsatisfactory associations; the sixteen altars bearing her image and name found in the island of Walcheren in 1647 are taken as evidence of her former influence. (Grimm's *Deutsche Mythologie*.)

Nell's Parabola. [PARABOLA; SEMICUBICAL.]

Neith. An Egyptian deity, who was regarded as an incarnation of nature, and as the patroness of all the arts. Her most celebrated temple was at Sais, where stood the famous veiled image.

Nelumbiaceæ (Nelumbium, one of the genera). In Botany, the name of a natural order of aquatic plants of great beauty, belonging to the Nymphal alliance, distinguished principally by its distinct carpels and large honeycombed torus. The only genus is *Nelumbium*, which comprises two or three very handsome species. One of them, *N. speciosum*, is believed to be the Sacred Lotus, or Pythagorean Bean. The nuts of all the species are wholesome and edible, and the rootstock is also sometimes eaten.

Nem. Con. A contraction for (Lat.) *nemine contradicente*, signifying no one contradicting; *nem. diss.*, contracted for (Lat.) *nemine dissente*, signifies no one dissenting.

Nemalite (Gr. *νέμος*, wood; *λίθος*, stone). A fibrous variety of Brucite.

NEOCOMIAN

Nematodeans (Gr. *νηματόδης*, *filiform*). The name of an order of *Celemintha*, or cavity intestinal worms, comprehending those which are dioecious, and have a round, filiform, elongated body.

Nematoneura (Gr. *νήμα*, and *νεῦρον*, nerve). A name proposed for that division of the *Radiata* of Cuvier, including animals in which nervous filaments are distinctly traceable, and the alimentary canal floats loosely in a distinct abdominal cavity.

Nemean Games. One of the four great national festivals of Greece, in which all the states participated. [GAMES.] They were celebrated at Nemea, a village in the north-eastern part of Argolis. By some they are said to have been established by the Epigoni, children of the warriors who besieged Thebes; but other versions of the myth relate that they were first instituted by Hercules after his victory over the Nemean lion. They were held every third year, under the presidency of citizens chosen by lot from the states of Argos, Corinth, and Cleonæ. The games were the same as those of Olympia. The victorious combatants were crowned with parsley.

Nemesis (Gr. *distribution*). This word, which in the *Iliad* is used only to express any cause of anger or righteous indignation, becomes in the Hesiodic *Theogony* the name of a daughter of Nyx, the night (or, according to another version, of Erebus). Starting with the notion of mere apportionment whether of good or evil, the idea of the goddess assumed afterwards a harsh and forbidding character, and she became especially the punisher of those on whom Fortune, *τύχη*, had bestowed her favours too lavishly. This idea of Nemesis suggests a comparison with the later notions of Atë, and ERINYs. Nemesis had a celebrated temple at Rhamnus in Attica; and her earlier statues are said to have resembled those of Aphrodité. She is generally represented as a virgin deity; but there was a legend that from an egg born of Nemesis sprang Helen and the Dioscuri, Castor and Polydeukes. [POLLEX.]

Nemocera (Gr. *νήμα*, a thread, and *κέρας*, horn). The name of a family of Dipterous insects, including those which have long filiform antennæ.

Nemoglossata (Gr. *νήμα*, and *γλῶσσα*, a tongue). The name of a tribe of Hymenopterous insects, including those which have a long filiform tongue, as the bee tribe.

Nemophila (a name coined from Gr. *νέμος*, a grove, and *φιλέω*, I love). A genus of beautiful annual flowers very popular amongst amateur gardeners, from their free-flowering habit and brilliant colours. It belongs to the order *Hydrophyllaceæ*, and in *N. insignis*, which has blue flowers with a white centre, yields perhaps one of the gayest of flower-garden ornaments.

Neocomian. The rocks of the lower division of the Cretaceous period, including part of the Wealden, bear this name on the continent of Europe. They form an extensive and important series of deposits in the neighbourhood

NEOCORUS

of Neufchâtel in Switzerland. There are two divisions. The Lower Neocomian represents the greater part of the Lower Greensand and some Upper Wealden beds. The Upper Neocomian is the uppermost division of the Lower Greensand much more largely developed than in England.

The Neocomian beds in Switzerland and elsewhere on the Continent are well supplied with characteristic fossils, which agree on the whole with those of the corresponding beds in England.

Neocorus (Gr. *νεωκόρος*, literally *a temple sweeper*). In Grecian Antiquities, the title of officers employed as guardians of temples and their treasures.

Neolite (Gr. *νέος*, *new*, and *λίθος*, *stone*). A massive variety of Talc in which part of the silica is replaced by alumina. It is found at the Aslak iron mines, near Arendal in Norway.

Neologism (Gr. *νέος*, and *λόγος*). The introduction of a new phrase or word into a language, or any innovation on ordinary modes of expression. Most European tongues have their classical diction fixed by precedent and authority; and words introduced by bold or careless writers, since this standard was established, go by the name of neologisms until usage has added them at last to the received national vocabulary.

Neology. In the last century, this name was given by orthodox divines in Germany to the novel system of interpretation which then began to be applied by many to the records of the Old and New Testaments. [RATIONALIST.]

Neomenia (Gr. *the time of the new moon*). The name given by the Greeks to the beginning of the month of the lunar calendar.

Neophyte (Gr. *νεόφυτος*, *newly planted*). In the primitive church, newly converted Christians were so termed; and the same appellation is still given in the Roman church, to converts made by missionaries among the heathen, to any person entering on the priestly office, and to those persons newly received into the communion of the church.

Neoprase (Gr. *νέος*, *new*; *πράσις*, *formation*). A native sulphate of iron found at Fahlun, in Sweden. [BOTRYOGENE.]

Neoplatonists. In Ancient Literature, the mystical philosophers of the school of Ammonius Saccas and Plotinus are commonly so called, who mixed some tenets of ancient Platonism with others derived from a variety of sources, and particularly from the demonology of the East. They flourished in the fourth and fifth centuries of the Christian era. Some, however, have contended that this title is more properly applicable to the eclectic Platonists, or school of Antiochus and Philo. [PLATONISTS; ECLECTICS.] For a singular view of the doctrines and tendency of the Neoplatonists, the reader may consult the *Quarterly Review*, July 1840.

Neotokite (Gr. *νέος*; *τόκος*, *a birth*). An amorphous mineral of a black or brownish-

NEPHELIUM

black colour found at Gäsbole in Finland. It is, probably, an altered form of Rhodonite, produced by the weathering of other minerals.

Neotype (Gr. *νέος*, and *τύπος*, *a form*). A variety of Natrocalcite containing Barytes.

Nepenthaceæ (Nepenthes, one of the genera). A natural order of subshrubby climbing plants referred by Lindley to his Euphorbial alliance, and distinguished by some technical points in the structure of the seeds. They are, however, to be recognised with ease and certainty by their external characters. The leaves, for instance, are more or less elongated, and their midrib is extended beyond the apex in the form of a tendril, which in the perfect condition of the plant supports a pitcher-like body provided with a jointed lid. They afford some of the most curious objects to be met with amongst plants. *Nepenthes* is the only genus, but there are many species known, several of which are to be found in the hot-houses of the curious.

Nepenthe (Gr. *νηπενθής*, *removing sorrow*). A magic potion, mentioned by the Greeks and Romans, which was supposed to obliterate pain and sorrow from the memory of those who partook of it. The mixture given under this name by Helen to the guests of Menelaus is said to have been obtained from the Egyptian Thebes; hence the term *Thebaic tincture*, applied to tincture of opium, or *laudanum*. The word is now used figuratively to express any remedy which gives rest and consolation to an afflicted mind.

Nepeta (Ital. *nepatella*, *cat-mint*). The genus of the Catmint, a common wayside weed of the labiate order, particularly attractive to cats. This catmint is *N. cataria*, sometimes called *Nep*.

Nephalia (Gr. *νεφέλαι*, *sobor*). Certain Grecian sacrifices in honour of various deities, so called because no wine was offered during their celebration.

Nephele (Gr. *νεφέλη*, *a cloud*). In Greek Mythology, the wife of Athamas, and mother of PHRIXUS and HELLIS, who are thus literally the children of the mist.

Nepheline (Gr. *νεφέλη*). A double silicate of alumina and soda found at Capo di Bove, near Rome, and on Monte Somma, near Vesuvius, in fine white crystals lining cavities in the older lavas, with Idocrase, Mica, Hornblende, &c. Transparent fragments immersed in nitric acid assume a clouded appearance (whence the name). It is also known by the name of *Sommeite*.

Nephelium (Gr. *νεφέλη*). This genus, which belongs to the order *Sapindaceæ*, contains three celebrated exotic fruits, the Litchi or Leeches of China, the Longan of China, and the Rambutan of Malaya. The Litchi produces nearly round fruit, an inch and a half in diameter, containing a sweet jelly-like pulp; the Longan is smaller, and possesses an agreeable subacid flavour; and the Rambutan, which is of an oblong form and about two inches long, is esteemed for its pleasant acidulous

NEPHRALGIA

pulp. All these are small trees with pinnated leaves.

Nephralgia (Gr. *νεφρός*, the kidney; *ἄλγος*, pain). Pain in the kidney.

Nephrite (Gr. *νεφρός*). A hard tough mineral occurring in compact masses of a leek-green colour, passing into grey and greenish-white, on the western coast of New Zealand. The name more commonly given to Nephrite is Jade, of which there are two kinds: White or Oriental Jade; and Green Jade, the Jaddite of Damour. Both these varieties are silicates of alumina, and of other bases, as lime, magnesia, soda, protoxide of iron, &c., and both are only broken, or cut and polished, with great difficulty. Oriental Jade is the well-known material of a pale greenish-white colour, which is brought to this country from the eastern parts of Asia, carved into various articles with a beautiful polish, a manufacture for which the Chinese are very celebrated. Green Jade is more rare than the Oriental kind, and valuable in proportion. The colour, which varies from apple-green (like that of Chrysoprase) to a sort of emerald-green, is probably due to oxide of nickel. The name Nephrite probably originated in the circumstance of small plates of the mineral having been formerly worn suspended from the neck for the cure of diseases of the kidneys.

Nephritis (Gr. from *νεφρός*). Inflammation of the kidney. This disease is attended by pain in the affected part, extending along the ureter, and increased on walking, or in the upright posture: nausea and vomiting are common attendants, and the appearance of the urine is generally far from healthy. Bleeding, warm baths, sudorifics, and aperients, with opiates and diluents, are the principal remedies resorted to.

Nephrodium (Gr. *νεφρός*, and *εἶδος*, likeness). A genus of Ferns, closely allied to *Lastrea*, belonging like it to the Aspidiaceous group, and like it also having the sori covered by reniform indusia; but in *Nephrodium* the veins of the pinnule-like segments anastomose in a connivent manner with those of adjoining segments for a greater or less distance from the rachis of the pinna, as the segments are more or less united. They are for the most part tropical plants.

Nephrotomy (Gr. *νεφρός*; *τέμνω*, I cut). The operation of extracting a stone from the kidney.

Nepidae. [HYDROCORISÆ.]

Nepotism (Lat. nepos). A word invented to express a peculiar characteristic of many high ecclesiastics in Roman Catholic countries, and more particularly of popes: a propensity, namely, to aggrandise their family by exorbitant grants and favours conferred on members of it; literally, on nephews (nepotes). Many of the highest and wealthiest families of the Roman nobility owe their elevation entirely to this species of patronage.

Neptune (Lat. Neptunus). In Astronomy, the planet of our system the most distant from

NEREIDANS

the sun. The existence of this planet was predicted, and its place in the heavens announced within one degree of the truth, independently by two astronomers—Professor Adams and M. Leverrier—before it was discovered by the telescope. This triumph of mathematical skill marks an epoch in astronomy and sets a seal on the theory of universal gravitation which formed the basis of the method of prediction. Its existence was first suspected in consequence of irregularities in the movement of the planet Uranus, which baffled all attempts to attribute them to perturbation caused by known bodies. As far back as 1841 Mr. Adams determined to investigate the problem, and by September 1846 the new planet had fairly been grappled. On July 29 in that year the equatorial of the Cambridge Observatory was first employed in the search after the planet, the probable place having been stated by Mr. Adams. M. Leverrier, who had been working independently at the same problem, published his researches on August 31; and in a letter to the Berlin astronomers, which reached them on September 23, he assigned the place where he expected it would be found. This place was not one degree from that assigned to it by Mr. Adams. On the same evening, thanks to the Berlin star maps, which had not reached England, the planet was discovered.

As Neptune's nearest approach to us is 190,000,000 miles, it is invisible to the naked eye. Its diameter is 4.72 greater than that of the earth. Its revolution round the sun is accomplished in 60126.72 days. Neptune is accompanied by a satellite, the distance of which from the primary is nearly equal to that of our moon—225,000 miles; it accomplishes its revolution in 5 days 21 hours 8 minutes. Of the physical constitution of the planet we know nothing except its mass and density; these, as compared with the mass and density of the earth, are 18.900 and 0.321 respectively.

NEPTUNE. In Mythology. [POSEIDON.]

Neptunian. A name formerly given to a school of geologists which taught (with Werner) that all the great deposits and accumulations of rock had taken place in the presence of water, and from solution or suspension in water. That a very large proportion of all rocks have been so formed, is now placed beyond a doubt by evidence derived from the fossils which they contain; and that many more, generally thought plutonic, have been originally formed in contact with water and with water as an essential element, is also certain. Still there is no doubt that certain rocks, such as lavas at present and basalts anciently, are distinctly igneous, and that many of the plutonic rocks have been formed at great depths, at high temperature and under enormous pressure, although probably not without the presence of liquid water. The discussions concerning the *Vulcanists* and *Neptunists* are now only interesting as connected with the early history of geology.

Nereidans. The name of the family of

NEREIDES

dorsibranchiate Anellidans of which the genus *Nereis* is the type. The characters are, an even number of tentacula attached to the sides of the base of the head, and a little farther forwards two others which are biarticulate, between which are two simple ones. Their branchiæ consist of small laminae, between which is spread a network of vessels; each foot is also furnished with two tubercles, two packets of bristles, one cirrus above and another beneath.

Nereides (Gr. *Νηρηίδες*). The daughters of Nereus, and nymphs of the sea. They were originally conceived to be of a beautiful form, but later fictions degraded them to the idea of a mermaid. Among the most famous of these nymphs were Amphitrite, Galatea, Thetis, &c. [*Nymphs*.]

Nereus (Gr.). A sea-god, son of Ocean and Earth, standing to Poseidon in the same relation in which Gæa stands to Dêmêtér, or Helios to Phœbus.

Nerita (Lat., the name of a shell-fish in Pliny). This term was applied by Linnæus to a genus of his *Vermes Testacea*, characterised by having a shell with the columella in a straight line, which renders the aperture of a semicircular form: this aperture is always closed by an operculum. The genus is ranked by Cuvier amongst his Pectinibranchiate Gastropoda, and is subdivided into the subgenera *Natica*, Lam., *Nerita*, *Voluta*, and *Neritina*, Lam. *Nerita* proper is a marine shell, while *Neritina* is an inhabitant of fresh waters. Examples of both genera are found fossil in the strata of the Paris basin.

Nerium (Gr. *νέρβος*, *humid*). To this genus of *Apocynaceæ* belongs the well-known Oleander, a shrubby plant, with long willow-like leathery leaves, and terminal clusters of large rose-coloured flowers. It is very ornamental, but like many others of its order is furnished with a poisonous juice.

Neroli. The name given by perfumers to the essential oil of orange flowers. It is procured by distillation with water in the same way as the other volatile oils. The oil of the leaf of the orange-tree (*essence de petit grain*) is sometimes substituted for it.

Nervation. In Botany, the manner in which the veins of the leaves &c. are arranged.

Nerves (Lat. *nervus*, Gr. *νῆρον*). In Botany, the ribs or principal veins of the leaf.

Nervous Fever. This term was formerly used to indicate a condition now recognised as a variety in typhoid fever, in which nervous symptoms, or sensorial debility, are especially prominent. The treatment consists in allaying irritation and supporting the strength.

Nervous System. In Physiology. The nerves are fibrous chords in direct or indirect connection with the brain, and extending their ramifications into every part of the body. Their ultimate structure is filamentous, and they consist of a peculiar grey substance, their size depending upon the number of filaments enclosed in the common sheath. They are

NERVOUS SYSTEM

often so interwoven as to form a kind of network or *plexus*; and some of them have what are termed *ganglia*, or rounded masses of nervous matter, not fibrous, but apparently composed of globules disseminated through a vascular network.

There are two distinct systems of nerves; one of which is connected with the brain and with the spinal chord. These, being media of sensation and of voluntary motion, are termed the nerves of *animal life*, or the *cerebro-spinal* nerves. The other system is in communication with the brain and spinal chord, or with the cerebro-spinal nerves, only by very small filaments, and they have numerous ganglions throughout their course; they preside over the nutritive functions, upon which the mind has no direct influence: these are the nerves of *organic life*, or *ganglionic* or great *sympathetic* nerves.

The cerebro-spinal nerves convey impressions from their extremities to the brain, and they also convey the influence of the will from the brain to the voluntary muscles; these passing and repassing, or receptive and emissive, influences, are conveyed by distinct sets of nervous filaments, which, however, are generally enclosed in the same sheath, and therefore appear to form a single nerve: the terms *centripetal* and *centrifugal* filaments have been distinctively applied to them.

The history of the nervous system in all its details forms an extended and complicated, but a highly important part of anatomy and physiology, and the investigations connected with them have led to many useful practical results, which, however, have thrown but little light upon the cause of the phenomena, or the ultimate nature of the nervous influence. The works of Sir Charles Bell, Dr. Marshall Hall, and Dr. Wilson Philip must be consulted in reference to the functions of the different classes of nerves; there is a good general account of the subject in Baly's translation of Müller's *Physiologie*.

NERVOUS SYSTEM. In Comparative Anatomy. In some of the lowest-organised animals the nervous system has been detected in the form of simple filaments; these are afterwards found connected with a nervous ring surrounding the cesophagus. As organisation advances, nervous matter begins to be accumulated upon the ring, forming a brain; and upon different parts of the radiating filaments, forming ganglions.

When the principal gangliated filaments are not parallel, or not symmetrical in their course, they are associated with the type of organisation which characterises the molluscos or *heterogangliate* division of animals. When the gangliated filaments are two in number, symmetrical, and run parallel with each other along the ventral aspect of the body, they are associated with and bespeak the type of organisation characteristic of the articulate or *homogangliate* division. When the brain ceases to present the form of a ring, and sends down the back a prolongation of its sub-

NERVURES

stance, called the spinal marrow, the rest of its organisation is that which characterises the vertebrate or *myelencephalous* subkingdom, or primary division of animals. In the vertebrate and articulate animals the superficial tract of the spinal or ventral chords is *sensitive*, the deeper-seated tract *motive*.

Nervures. In Entomology, corneous tubes serving to expand the wing and keep it tense, as well as to afford protection to the air-vessels: they are termed costal, post-costal, mediastinal, externo-median, interno-median, anal, axillary, &c. according to their relative positions.

In Botany, *nervures* are the veins of leaves. [NERVES.]

Nesodon (Gr. νῆσος, *island*, and δῶνς, *tooth*). A genus of fossil Toxodont Mammalia from the pliocene strata of Port St. Julian, Patagonia. The *Nesodon ovinus* was as large as a sheep; the *Nesodon unbricatus* the size of a llama.

Ness. The termination of several names of places in Great Britain where there is a headland or promontory, as Inverness, Sheerness. The word is probably akin to the Fr. nez, the Ger. nase, Lat. nasus, *nose*.

Nestorians. The followers of Nestorius, patriarch of Constantinople, in the first half of the fifth century. This prelate agitated the Christian world, after the Arian controversy had been settled, by the introduction of certain subtle disputations concerning the divine and human natures in Christ, between which he affected to distinguish with peculiar precision; and, in guarding against the propensity which he discovered in the Christians of his own day to confuse the two and look upon them as absorbed into one compound substance, he forbade men to entertain any combined notion at all, and kept constantly before their eyes both the God and the man. He insisted, for instance, that the Virgin should not be entitled *Mother of God*, but *Mother of Christ*, or of *Man*, the human nature being essentially distinct from and only inhabited by the divine, as a temple by its divinity. Nestorius was condemned by the third general council held at Ephesus, in the year 431: his principal adversary being the president of the assembly, Cyril, patriarch of Alexandria. After his deposition, he was banished by the emperor to an oasis in Upper Egypt, where he died. His opinions, however, spread throughout Asia, and appear to have been carried along, with the advancing stream of Christianity, to the farthest parts of India and China. In the more Western regions, they were soon afterwards counteracted by the spread of the opposite theories of Eutyches. [EUTYCHIAN; MONOPHYTES; MONOTHELITES.] Besides the well-known authorities, the reader may consult Doucin, *Histoire du Nestorianisme*, 1698; Asseman's *Bibliothèque Orientalis*; Grant's *Residence among the Nestorian Christians*, 8vo. 1841; Milman's *Latin Christianity*, book ii. ch. iii. [THREE CHAPTERS.]

Nests, Esulent. A species of nests built

NEURAL ARCH

by swallows, peculiar to the Indian islands, and much esteemed in China and other parts of the world. These nests resemble in form those of other swallows; they are formed of a viscid substance, and in external appearance as well as consistence are not unlike fibrate ill-concocted isinglass. Esulent nests are principally found in Java, in caverns usually situated on the sea-coast. Nothing satisfactory is known as to the substance of which these nests are composed. (*Commercial Dictionary*, art. 'Birds' Nests.')

Net (Ger. *netz*). A textile fabric of knotted meshes, for catching fish and other purposes. Each mesh should be so secured as to be incapable of enlargement or diminution. The French government offered in 1802 a prize of 10,000 francs to the person who should invent a machine for making nets upon automatic principles, and adjudged it to M. Buron, who presented his mechanical invention to the *Conservatoire des Arts et Mètièrs*. It does not appear, however, that this machine has accomplished the object in view; for no establishment was ever mounted to carry it into execution. Nets are usually made by the fishermen and their families during periods of leisure.

Net or Neat (Fr. *net*, from Lat. *nitidus*, *shining*: Wedgwood). In Commerce, something pure and unadulterated with any foreign mixture. Thus, wines are said to be *net* when not falsified; and coffee, rice, &c. to be so, when the filth and ordures are separated from them. The word *net* is also used for what remains after the tare has been taken out of any merchandise; i.e. when it is weighed clear of all package. [TARE.] *Net produce* (Ital. *netto proceduto*) is used in mercantile language to express what any commodity has yielded, after all tare and charges have been deducted.

Nethinims. Among the Jews, the servants of the priests and Levites, employed in the lowest and meanest offices about the temples. They are termed 'the hewers of wood and drawers of water for the house of God,' an office to which the descendants of the Gibeonites are stated to have been condemned by Joshua.

Nettings. Nets of small rope placed in a ship for various purposes, as stowage, or defence against accidents; also against boarding.

Nettle (A.-Sax. *netele*). The common name of the plants of the genus *URTICA* [which see], well known on account of their stinging property.

Nettlerash. An eruption upon the skin much resembling that produced by the sting of a nettle. It usually lasts for a few hours, and then disappears or changes its place; it is generally relieved by mild aperient medicines.

Neukirchite. A kind of Wad found at Neukirchen in Alsace, forming a coating on Red Hiematite.

Neural Arch (Gr. νῆρον, *a nerve*). In Anatomy, the arch of the vertebra or primary segment of the skeleton which protects a corresponding segment of the neural axis: it is posterior in man, superior in other vertebrates,

NEURAL AXIS

and is formed below by the *centrum*, laterally by the *neurapophyses*, and above by the *neural spine*.

Neural Axis. In Anatomy, the central trunk of the nervous system, consisting of brain and myelon: it is sometimes called *cerebro-spinal axis*.

Neuralgia (Gr. *νεῦρον*, and *ἀλγός*, *pain*). An acute painful affection in the course of the nerves. The forms of neuralgia most commonly met with are sciatica, lumbago, and tic douloureux. The two former receive their name from the nervous parts affected, viz. the sciatic and the lumbar nerves; the latter from the sudden and severe stroke of pain experienced. This latter affection frequently observes a curious periodicity: its usual seat is in the fifth nerve and its branches.

Neurapophysis (Gr. *νεῦρον*, and *ἀπόφυσις*, a *process*). In Anatomy, the autogenous vertebral element which forms the side or wall of the arch protecting the neural axis or central trunk of the nervous system: it has been called the *vertebral lamina*, and by Soemmering the *radix arcus posterioris vertebræ*.

Neurility or Neuricity (Gr. *νεῦρον*). The property of the fibrous structure of the nerves.

Neurilite (Gr. *νεῦρον*, and *λίθος*, *stone*). A hydrated silicate of alumina and lime, with a fibrous structure, from Stamestead in Lower Canada.

Neurology (Gr. *νεῦρον*, and *λόγος*). The anatomy of the nervous system.

Neuropterans (Gr. *νεῦρον*, and *πτερόν*, a *feather*). The order of Tetrapterous Mandibulate insects, including those in which the nervures of the wings are so disposed as to form a more or less regular network. They are distinguished from the Colcopterous, Orthopterous, and Hemipterous orders of four-winged insects, by the first or anterior pair of wings being membranous, diaphanous, and resembling the second pair in texture and properties. The abdomen is unprovided with a sting. The antennæ are usually setaceous. Some neuropterans merely pass through a semi-metamorphosis, the rest a complete one; the larvæ have always six hooked feet. Many of these insects are carnivorous in their first state and their last. The dragon-fly may be regarded as the type of this order.

Neuroskeleton (Gr. *νεῦρον*, and *σκελετός*, *dried up*). The deep-seated bones, which are connected with the nervous axis and locomotion.

Neurotics. Remedies which act upon the system.

Neurotomy (Gr. *νεῦρον*, and *τέμνω*, *I cut*). The cutting of a nerve.

Neuter (Lat. *neither*). In Grammar, this term comprises those nouns which are neither masculine nor feminine. *Neuter* or *intransitive* verbs are those which represent the properties of a state or process, as *I rest, I fall, I grow*, &c. [GRAMMAR.]

Neutr was the name given to the labourers of the hive-bee, before it was discovered that they were essentially females, though infertile.

NEW TESTAMENT

Neutral Equilibrium. [STABLE AND UNSTABLE.]

Neutral Salts. Combinations of acids and bases which are neither acid nor alkaline, but in which the acid is exactly *neutralised* by the base.

Neutrality. In International Law, the condition of a state which does not take part in a war between other states. A neutral nation has the right of furnishing to either of the contending parties all supplies which do not fall within the description of *contraband of war* [CONTRABAND OF WAR], and to conclude treaties with either unconnected with the subject of the war. It appears to have been the old principle, with regard to the maritime trade of a neutral nation, that the property of an owner belonging to the hostile country might be seized by a belligerent on board a neutral power's vessel; but the general rule now asserted is that the flag covers the cargo: by which means right of search, except for specific purposes, is rendered unnecessary. By the declaration of March 28, 1854, made on the occasion of the Russian war, England waived the right of seizing enemy's property on board a neutral vessel, unless contraband, but did not abandon it.

Neuvaines (Fr. from *neuf*, *nine*). In the Roman Catholic Church, prayers offered up for nine successive days, in order to obtain the favour of Heaven. (*Dict. de la Conversation*.)

New Connexion Methodists or Kilhamites. A society so called from Alexander Kilham, who was the immediate means of their separation from the Wesleyans, from which body they withdrew on the ground of the almost irresponsible power exercised by the Conference. Their number is not considerable.

New Red Sandstone. This name is given by geologists to a group of sandstones, generally of a red colour, belonging to the lowest and oldest division of the secondary period, and distinguished by fossil contents from some other important sandstones, also of a red colour, but in rocks below the carboniferous limestone. The latter are called OLD RED SANDSTONE [which see]. The series as developed in England consists chiefly of coloured sandstones and marls containing enormous quantities of salt, both rock salt and saline springs, and much gypsum. It includes the upper and lower members of the TRIASSIC SERIES of the Continent, the MUSCHELKALK or shell limestone being absent. The sandstones are much used as building stone, and some of them near Liverpool and Warwick are remarkable as having upon them numerous footprints of animals, reptilians chiefly, but probably also birds. Except these footprints, fossils are rare in the new red sandstone in England, though many fragments of plants have been found from time to time, and some shells. In the Muschelkalk of the Continent there are many characteristic fossils.

New Style. In Chronology. [STYLE.]

New Testament. The name given to that portion of the Bible which comprises the

NEW YEAR'S DAY

Gospels and the Apostolic Epistles, with the Apocalypse or Revelation of St. John. The four Gospels bear the names respectively of Matthew, Mark, Luke, and John. These are followed by the Acts of the Apostles, which have been attributed to St. Luke, and by twenty-one Epistles, of which fourteen have been ascribed to St. Paul, three to St. John, two to St. Peter, one to St. James, and one to St. Jude. [BIBLE; BIBLICAL HISTORY; EPISTLE.]

New Year's Day. The celebration of the commencement of the new year dates from high antiquity. The Jews regarded it as the anniversary of Adam's birthday, and celebrated it with splendid entertainments—a practice which they have continued down to the present time. The Romans also made this a holiday, and dedicated it to Janus with rich and numerous sacrifices; the newly elected magistrates entered upon their duties on this day; the people made each other presents of gilt dates, figs, and plums; and even the emperors received from their subjects new year's gifts, which at a later period it became compulsory to bestow. From the Romans the custom of making presents on New Year's Day was borrowed by the Christians, by whom it was long retained; but even in those countries where it lingered longest, in France and Scotland for instance, it is falling rapidly into desuetude.

Newell. In Architecture, the space, either solid or open, round which the steps of a staircase are turned.

Newspaper Reporting. The system of reporting, by which the parliamentary debates and speeches delivered at public meetings, &c. are given to the public. As it is contrary to the rules of both Houses that any stranger should be present, the publication of the debates is held to be a breach of privilege; but this regulation has always been defeated, either, as in former times, by the means adopted by Dr. Johnson and others of publishing the speeches of the different members under fictitious names, or, as at present, by the Houses themselves tacitly giving their sanction to the practice. The foundation of the present system of parliamentary reporting may be fairly ascribed to the late Mr. William Woodfall, whose retentive memory enabled him, after having listened to the debates, daily to communicate to the public, in what he called *A hasty Sketch of the Proceedings in Parliament last Night*, a full and accurate account of the different speeches. Secret deliberations, however, have been so long renounced, that the right of the public to be present through their agents, the reporters, is as clearly established now as if no theoretical privacy had ever existed; but if any member were repeatedly to insist upon the exclusion of strangers, as all are called who neither are members nor officers of the house, there can be no doubt that this abuse of the privilege must lead to such a modification of the standing order as would deprive individual members of any control over a matter so interesting to the nation. The process of parliamentary reporting

NEWSPAPERS

and the qualifications of those by whom the task is performed, cannot be adequately described within the narrow limits of this article; but it is hoped that the reader may be enabled to form some idea of both from the following brief outline. Every publication not copying from or abridging any other, but giving original reports, keeps one of a series of reporters constantly in the gallery of the Lords, and another in the Commons. These, like sentinels, are at intervals of three-quarters of an hour relieved by their colleagues, when they take advantage of the respite to transcribe their notes, in order to be ready again to resume the duty of note-taking, and afterwards that of transcription for the press. A succession of reporters for each establishment is thus maintained, and the process of writing from their notes is never interrupted till an account of the whole debates of the evening has been committed to the hands of the printer. The publications for which reporters are constantly in attendance, are the London morning newspapers, from which all others that give debates are under the necessity of copying or abridging them. The number of reporters maintained by each varies from ten or eleven to seventeen or eighteen. They are for the most part gentlemen of liberal education—many having graduated at the universities of Oxford, Cambridge, Edinburgh, Glasgow, or Dublin. The expedition and ability with which their duties are performed must be admitted by every one who attends a debate and afterwards reads a newspaper; while the correctness and rapidity with which their manuscript is put in type and printed has long been a subject of surprise and admiration.

Newspapers. Publications in numbers, consisting commonly of single sheets, and published at short and stated intervals, conveying intelligence of passing events. In Rome, under the government of the emperors, periodical notices of passing events [ACTA DIURNA] were compiled and published; but our accounts of these ancient newspapers are somewhat obscure and uncertain. In modern Europe, the earliest occasional sheets of daily intelligence seem to have appeared at Venice, during the war of 1563 against the Turks [GAZETTE]; and the earliest regular paper appears to have been a monthly one, published in the same city by the state: but these were distributed in manuscript, and, owing to the jealousy of the government, were circulated in this form down to very late times. Extraordinary gazettes are said to have been published in England by authority, during the time when the arrival of the Spanish Armada was apprehended; but the specimens preserved in the British Museum, and so long regarded as authentic, are now demonstrated to have been forgeries.

Genuine English newspapers date from the first year of the Long Parliament, the oldest that has been discovered being a quarto pamphlet of a few leaves, entitled *The Diurnal Occurrences or Daily Proceedings of both*

NEWSPAPERS

Houses, in the Great and Happy Parliament, from November 3, 1640, to November 3, 1641. More than one hundred papers with different titles appear to have been published from this time to the death of the king, and upwards of eighty from that date to the Restoration. These were at first published weekly, but as the interest increased, twice or thrice a week, and even, it would seem, daily, at least for a time. Such were the *French Intelligencer*, the *Dutch Spy*, the *Scots Dove*, &c., but *Mercuries* of all sorts were the favourite title. Thus they had the *Mercurius Acheronticus, Aulicus, Britannicus, Laughing Mercury*, and *Mercurius Mastix*, which last faithfully lashed all the rest. The great newspaper editors of the day were Marchmont Needham on the Presbyterian, and Sir John Birkenhead on the Royalist, side. These were followed by Sir Roger l'Estrange, who has been ranked amongst the patriarchs of the newspaper press. This journalist is admitted to have been by no means deficient in readiness and shrewdness; but the acrimony displayed in his Tory paper, *The Observer*, against his unfortunate political adversaries is frequently ungenerous and even cruel.

In 1685 (says Lord Macaulay) nothing like the London daily paper of our time existed, or could exist. Neither the necessary capital nor the necessary skill was to be found. Freedom too was wanting, a want as fatal as that of either capital or skill. The press was not indeed at that moment under a general censorship. The licensing Act, which had been passed soon after the Restoration, had expired in 1679. Any person might therefore print, at his own risk, a history, a sermon, or a poem without the previous approbation of any officer; but the judges were unanimously of opinion that this liberty did not extend to gazettes, and that, by the common law of England, no man, not authorised by the crown, had a right to publish political news. While the Whig party was still formidable, the government thought it expedient occasionally to connive at the violation of this rule. During the great battle of the Exclusion Bill many newspapers were suffered to appear, the *Protestant Intelligencer*, the *Current Intelligencer*, the *Domestic Intelligencer*, the *True News*, the *London Mercury*. None of these was published oftener than twice a week. None exceeded in size a single small leaf. The quantity of matter which one of them contained in a year was not more than is often found in two numbers of the *Times*. After the defeat of the Whigs, it was no longer necessary for the king to be sparing in the use of that which all his judges had pronounced to be his undoubted prerogative. At the close of his reign no newspaper was suffered to appear without his allowance: and his allowance was given exclusively to the *London Gazette*. The *London Gazette* came out only on Mondays and Thursdays. The contents generally were a royal proclamation, two or three Tory addresses, notices of two or

three promotions, an account of a skirmish between the imperial troops and the Janissaries on the Danube, a description of a highwayman, an announcement of a grand cockfight between two persons of honour, and an advertisement offering a reward for a strayed dog. The whole made up two pages of moderate size. Whatever was communicated respecting matters of the highest moment was communicated in the most meagre and formal style. . . . But the people who lived at a distance from the great theatre of political contention could be kept regularly informed of what was passing there only by means of newsletters. To prepare such letters became a calling in London, as it now is among the natives of India. The news-writer rambled from coffee-room to coffee-room, collecting reports, squeezed himself into the Sessions House at the Old Bailey if there was an interesting trial, nay, perhaps obtained admission to the gallery of Whitehall, and noticed how the king and duke looked. In this way he gathered materials for weekly epistles destined to enlighten some county town or some bench of rustic magistrates. Such were the sources from which the inhabitants of the largest provincial cities, and the great body of the gentry and clergy, learned almost all that they knew of the history of their own time. . . . It is scarcely necessary to say, that there were then no provincial newspapers. Indeed, except in the capital and at the two universities, there was scarcely a printer in the kingdom. The only press in England north of Trent appears to have been at York. For the history of the newspaper press from this period to the end of the seventeenth century, see Macaulay's *History*, vol. iv. pp. 604-606.

From their first imperfect beginning, newspapers have gradually increased in number, matter, and consequence, until they form, in many European countries, one of the most important features in the social economy of the people; exercising a marked influence on domestic manners, literature, and usages, but more especially powerful as a great political instrument. London newspapers, and indeed many of the principal provincial papers also, are remarkable for the great mass and variety of matter which they contain, the ability of their leading articles, the rapidity with which they are printed and circulated, and the accuracy and copiousness of their debates. The piracy existing in the newspaper press is a difficulty under which the leading newspapers are placed in consequence of the want of any available copyright in the news or articles which they supply.

In Great Britain newspapers are subjected to several statutory enactments. By 6 & 7 Wm. IV. c. 76 no person can print or publish any newspaper until a declaration has been delivered at the Stamp Office, stating the name and places of abode of the printer, publisher, and proprietor; specifying the amount of shares in the undertaking, the title of the paper, and de-

NEWSPAPERS

scription of the building in which it is intended that the paper shall be printed. A copy of every newspaper is to be delivered, upon the day of publication, to the commissioners of stamps, under a penalty of 20*l*. Persons publishing newspapers without the name and place of abode of the printer affixed, are made liable to a penalty of 20*l*. for each offence, and peace officers, by virtue of a warrant from a justice of the peace, may enter any place to make search, &c. By 60 Geo. III. c. 9 every periodical, pamphlet, or paper, published at intervals not exceeding twenty-six days, containing public news or intelligence, or any remarks thereon, or on any matter in church or state, not containing more than two sheets, or published at a less price than sixpence, shall be deemed newspapers. By 1 Wm. IV. c. 73 securities may be demanded, to the amount of 400*l*. or 300*l*., from both principal and sureties, when it is intended to publish a newspaper or pamphlet of the description mentioned in 60 Geo. III. c. 9. These securities are intended to secure payment of damages or costs which may be incurred in an action for libel against the conductor of the paper. The stamp duties on newspapers were repealed in 1859. By 18 & 19 Vict. c. 27 it is not compulsory to print newspapers on paper stamped with the duty imposed by 13 & 14 Vict. c. 97, except for the purpose of their transmission by post free of charge.

In France newspapers are generally undertaken in shares. The editors and principal writers are more responsible and more generally known than in England: this is either a cause or an effect of the general prejudice in that country against anonymous writing, which is by no means so common as among ourselves, but perhaps one of its consequences is, that newspapers are more notoriously under the control of particular sections of the political world, or of powerful individuals. Political newspapers have their subsidiary articles on subjects of theatrical or literary criticism added in the shape technically termed *feuilleton*, a subdivision of the page. This custom was introduced about 1800 in the most influential paper of that period, and has since been generally followed. The periodical press of France was under strict control during the Empire; the censorship was continued until 1819, and re-established in 1820, but again abolished in 1821. At that period a law was passed compelling the proprietors to give security for the good conduct of their journals, under a penalty of 10,000 francs in Paris, and various lesser sums in the departments. The censorship was, however, again instituted, and again abolished in 1827. By the famous ordinances of 1830 the liberty of the periodical press was suspended. In 1835, laws of a very severe character were passed, to subject the proprietors of journals to easier conviction and heavier punishment, in case of transgressing the existing laws of libel against government or individuals, and extending and multiplying the provisions of that

NEWTON'S RULE

law. In December 1851, the revolutionary government of Louis Napoleon Bonaparte commenced its career with a sweeping suppression of the press unparalleled in modern times. The *Gazette de France* appeared regularly from 1631 to 1792, forming a collection of 163 volumes; it was continued, also, but with some interruptions, through the period of the Revolution.

According to Mitchell's *Newspaper Press Directory* for 1865, the present position of journalism may be thus stated:—

There are 1,271 journals published in the United Kingdom, distributed as follow:—

England	944
Wales	41
Scotland	140
Ireland	132
Channel Islands	14

The daily papers published in the United Kingdom may be distributed as follow:—

England	48
Wales	1
Scotland	11
Ireland	12
Channel Islands	1

And these may be particularised thus:—

In ENGLAND: Birmingham, 2; Bristol, 3; Hull, 2; Leeds, 1; Liverpool, 5; London, 20; Manchester, 3; Newcastle, 3; Nottingham, 3; Plymouth, 2; Sheffield, 2; Shields, 1; Sunderland, 1.

In WALES: Cardiff, 1.

In SCOTLAND: Dundee, 2; Edinburgh, 4; Glasgow, 4; Greenock, 1.

In IRELAND: Belfast, 2; Cork, 4; Dublin, 6.

In the CHANNEL ISLANDS: Jersey, 1.

In the United States, newspapers have made rapid strides, if we regard only the quantity of matter; between two and three thousand separate newspapers being published, with a circulation which may be counted by millions.

Newton's Rule. In Algebra, a rule given by Sir I. Newton, in his *Arithmetica Universalis*, part ii. chap. ii., for finding limits to the number of positive and to the number of negative roots of an equation. Prof. Sylvester, who was the first to demonstrate this rule, describes it thus, in a paper first published in the *Proceedings of the London Mathematical Society* (1865):

$$f(x) = a_0 x^n + n a_1 x^{n-1} + \frac{n(n-1)}{1.2} a_2 x^{n-2} + \dots + n a_{n-1} x + a_n = 0,$$

being an equation of the n^{th} degree, $a_0 a_1 \dots a_n$, are termed its *simple elements*, and

$$A_0 = a_0^2, A_1 = a_1^2 - a_0 a_2, \dots$$

$$A_{n-1} = a_{n-1}^2 - a_{n-2} a_n, A_n = a_n^2$$

its *quadratic elements*. Further, a_r, a_{r+1} is termed a *succession* of simple, and A_r, A_{r+1} a succession of quadratic elements: $\left. \begin{matrix} a_r & a_{r+1} \\ A_r & A_{r+1} \end{matrix} \right\}$ being an associated couple of successions.

NEWTONIAN PHILOSOPHY

Now each succession in an associated couple may contain a *permanence* or a *variation* of signs. Thus an associated couple may consist of two permanences (*double permanence*), of a superior variation and inferior permanence (*variation-permanence*), and so on. These denominations being accepted, Newton's rule, in its complete form, may be stated thus:—

'On writing the complete series of quadratic under the complete series of simple elements of $f(x)$, in their natural order, the number of double permanences in the associated series so formed is a superior limit to the number of negative roots, and the number of variation-permanences in the same is a superior limit to the number of positive roots in $f(x)$.' As a corollary it follows that the number of imaginary roots cannot be less than the number of variations in the series of quadratic elements.

Prof. Sylvester has also greatly generalised the rule of Newton; for instance, he gives a theorem having the same relation to Newton's rule that Fourier's theorem bears to Descartes' rule.

Newtonian Philosophy. This term is used in various senses. Sometimes it is used to denote the doctrine of the universe as delivered by Sir Isaac Newton in the *Principia*; sometimes the corpuscular, or modern, or experimental philosophy, as opposed to the theories of Descartes and others; but most frequently, perhaps, the mathematical theory of universal gravitation. [GRAVITATION; PHYSICS.]

Nexi (Lat. part. of *necto*, *I bind*). In Roman Antiquities, persons freeborn, who, for debt, were delivered bound to a creditor, and obliged to serve him until they could discharge it. On the abolition of the law of Nexum, see Sir G. C. Lewis *On the Credibility of Early Roman History* ii. 479.

Next Friend of an Infant or Married Woman. In Law, one who institutes and conducts suits in equity in the name and on behalf of the party. Any person *sui juris* may act in this capacity, provided his interest is not adverse to that of the party. In the case of a married woman, her consent must be obtained; but no consent is necessary in the case of an infant. In either case the next friend is responsible for the costs of the proceedings.

Nibelungen, Lay of the. The name given to the most ancient existing monument of German epic poetry. It is supposed to have existed, in substance at least, two centuries before the reign of Charlemagne, and, like the early compositions of poets in all ages, to have consisted originally of detached ballads and poems, which were afterwards gradually collected, and at length moulded into the complete form in which they at present exist. [EPIC.] The last of the modifications which it underwent took place towards the end of the twelfth century, and is attributed to the Minnesinger Heinrich von Ofterdingen. The story turns upon the adventures of Kriemhilt, who is localised in Burgundy, and is first won by the valiant Siegfried, and after he is treacher-

NICARAGUA WOOD

ously murdered gives her hand to Atli (identified with Attila, king of the Huns), chiefly in the hope that through his power and influence she may be revenged on the murderers of her former lord. The assassins, accordingly, and all their kin, are induced to visit Atli, when, by the instigation of the queen, a deadly feud arises, in the course of which almost the whole army on both sides is cruelly slaughtered. By the powerful but reluctant aid of Dietrich of Bern (Theodoric, who conquered Odoacer at Ravenna, in the famous Rabenschlacht, and lived at Verona, Bern), the murderer of Siegfried is at last vanquished, and brought bound to the feet of the queen, who relentlessly raises the sword of the departed hero, and with her own hand strikes off the head of his enemy. The famous Hildebrand, whose exploits are depicted in the *Heldenbuch*, instantly avenged the act by stabbing the queen, who falls exulting on the body of her hated victim. The work is divided into thirty-eight books. The *Nibelungen Lied* formed for many centuries the chief traditional record of the romantic deeds and sentiments of the German nation, but at the era of the Reformation it sank wholly into oblivion; from which, however, it has within the last thirty years been rescued, and permanently placed, by the labours and commentaries of Hagen, Zeune, Simrock, and Schlegel, among the most conspicuous monuments of human genius.

Among the heroic poems of those nations which, in contradistinction to those of the Greeks, whose skilful unfolding of incidents and dramatic vividness of representation were unrivalled, have remained satisfied with a more simple mode of poetry, the *Nibelungen Lied* claims a very high place—perhaps among all the heroic chivalrous poems of Northern Europe it is entitled to the first. It is a series of pictures, each naturally following the other, and all delineated with great boldness and simplicity, and a total disregard of all superfluities. The German language appears in this work in a state of perfection to which in the subsequent periods of its early history it had no pretensions. In the *Nibelungen Lied*, in the same manner as in the legends of Troy and of Iceland, the interest turns on the fate of a youthful hero, invested with all the attributes of beauty, magnanimity, and triumph, but dearly purchasing all these glories by the certainty of an early and predicted death. [MYTHOLOGY, COMPARATIVE.] If the last catastrophe of the German poem be more tragical than anything in the *Iliad*, the death of the German hero, on the other hand, has in it more solemnity, stillness, and tenderness. The groundwork of the lay is the same as that of the older *Volunga SAGA*. (Dasent's *Popular Tales of the Norse*, Introduction; Max Müller's *Comparative Mythology*, p. 68 &c.; Schlegel's *History of Literature*, Edin. 1818, vol. i. pp. 270, 272.)

Nicaragua Wood. The wood of the *Cecropia echinata*, a tree growing in Nic-

NICE, COUNCIL OF

ragua; it is a species of Brazil wood, and is used, with solution of tin as a mordant, to dye a bright but fugitive red.

Nice, Council of. The first ecumenical council held in the Christian church. It was convened, A.D. 325, at Nicea in Asia Minor by the emperor Constantine, in order to settle differences that had arisen in respect to the doctrines of Arius. This council was attended by upwards of 250 bishops, of whom a great majority came from the East, besides presbyters, deacons, and others from all parts of the Christian world. The chief question was the Arian heresy; and the council issued in the excommunication of Arius. [ARIANS.]

Nicene Creed. The confession of faith in which the consubstantiality of the Father and Son is asserted against the Arians. [ARIANS.] This creed was commenced by the council of Nice, A.D. 325, and completed by the second general council of Constantinople, A.D. 381. But the words 'and the Son,' after those 'Who proceedeth from the Father,' were added by the Latin church (certainly before A.D. 411), expressing a point of doctrine in which it differs from the Greek. The Nicene Creed was generally used by the Eastern churches in the administration of baptism; but was not inserted in their daily service till the fifth century. In the service of the church of Rome it was inscribed A.D. 1014.

Niche (Fr.; Ital. *nicchia*). In Architecture, a square or a cylindrical recess, formed in a wall, to receive a vase, statue, or other erect ornament.

Nickel. A white metal discovered by Cronsted in 1751; it is ductile, malleable, attracted by the magnet, and, like iron, may be rendered magnetic. Its specific gravity when hammered is about 9. It is rather more fusible than pure iron; is not altered by exposure to air and moisture at common temperatures, but is slowly oxidised at a red heat. It is found in meteoric iron. Its principal ore is a copper-coloured mineral found in Westphalia, and called *kupfernickel*, nickel being a term of detraction used by the German miners, who expected from the colour of the ore to find that it contained copper. It is also obtained from an impure arsenide, known under the name of Speiss. The salifiable oxide of nickel, NiO, consists of 30 nickel + 8 oxygen. Its salts are mostly of a grass-green colour, and the ammoniacal solution of its oxide is deep blue, like that of copper. Ferrocyanide of potassium precipitates it of a white or very pale green colour.

An alloy of nickel and iron forms an ingredient in most *aërolites* and in the masses of native iron found in various parts of the world, in which the proportion of nickel varies from 1.5 to 8.5 per cent. With copper, nickel forms a hard white alloy. The white copper of the Chinese, or *Pakfong*, consists of 40.4 parts of copper, 31.6 of nickel, 25.4 of zinc, and 2.6 of iron. A similar alloy is often used as a substitute for silver, or for plated articles, under the

NICTITATION

name of *German silver* or *Argentane*. These white alloys, when plated with silver, have over plated copper the advantage of not showing a red metal upon worn edges.

Nickel Bloom. Native arsenate of nickel. [NICKEL OCHRE.]

Nickel Glance. Native sulphide of nickel, sometimes containing arsenic and antimony.

Nickel Ochre. Native arsenate of nickel. It occurs in short capillary crystals of an apple-green colour; and also in earthy friable masses.

Nickel Pyrites. Native sulphide of nickel or Capillary Pyrites. [MILLERITE.]

Nickel Vitriol. A hydrated sulphate of nickel, occurring generally as a greenish-white efflorescence upon a sulphide of nickel and iron at Wallace Mine, Lake Huron.

Nickeline. [NICKEL OCHRE.]

Nicolaitans. One of the earliest Christian sects, mentioned in the Apocalypse, where the angel of God reproaches the church of Pergamos with harbouring persons of this denomination. They are there characterised as inclining to the licentious and pagan practices of the Gentiles; but the fathers have also accused them of partaking in a great measure of the Gnostic opinions. It is doubtful, however, whether on this point there be not some confusion between the Nicolaitans of the first and the followers of Nicolaus of the second century.

Nicolo. [ONICOLO.]

Nicotiana (so named after Jean Nicot, a Frenchman, who in the year 1560 first sent the seeds of tobacco into France). The genus of *Solanaceæ* to which the Tobacco plant belongs. The Tobacco of commerce is furnished by two or three species, but chiefly by *N. Tabacum*, a tall-growing annual plant, with large oblong lance-shaped leaves, and pink funnel-shaped flowers. This sort is largely cultivated in the southern states of America, in China, in Holland, Germany, France, &c. *N. rustica*, a smaller plant with ovate leaves and green flowers, is cultivated in many parts of the world: and *N. persica*, *repanda*, *quadrialvis*, *multivulvis*, and *lutissima* are also grown for their produce.

Tobacco forms an important article of commerce. In 1864 the total imports into the United Kingdom amounted to 66,615,176 lbs., the value of which was computed at 3,448,294*l.*, of which 37,951,928 lbs. were retained for home consumption, and yielded in duty a revenue of 6,080,181*l.* Snuff is manufactured by grinding the dried and prepared tobacco leaves.

Nicotianin. The essential oil of tobacco, obtained on distilling the leaves with water. It has the appearance of a camphor, and by distillation with caustic potash is said to give nicotine.

Nicotine. A volatile poisonous alkaline base, extracted from the leaves and seeds of the *Nicotiana Tabacum*, or common Tobacco, the physiological effects of which are due to this base.

Nictitation (Lat. *nicto*, *I wink*). Winking of the eyes. This is generally a nervous affec-

NIDDI

tion, and very frequently it becomes a trick or habit. Where it arises from any local irritating cause, bathing the eyes with warm water affords relief.

Niddul. A sort of minor excommunication among the Hebrews, which continued usually about a month. If not removed within that period, it was prolonged for sixty or even ninety days. If during this term satisfaction was not made, the excommunicated person fell into the *chirem*, which was the second species of excommunication; and afterwards into the *scammatha*, which was the most dreadful of all.

Niello (Ital.). A method of engraving on plate. [ENGRAVING.]

Nigella (Lat. dim. of niger, black). A small genus of *Ranunculaceæ*, containing a few rather pretty border flowers, *N. damascena*, *romana*, and *hispanica*, familiarly known by the name of Devil-in-a-bush; and comprising also the *N. sativa*, a black-seeded aromatic species, used in Eastern countries as a substitute for pepper.

Nigged Ashlar. A mode of dressing the surface of stone, in which the face is left rough, or dressed only with a pointed hammer, instead of a chisel; this kind of work is also known by the name of *hammer dressed*, and it is generally employed in basements, or rough masonry where the appearance of strength is desired.

Night Blindness. An affection of the eyes, supposed to be caused by a partial paralysis of the retina. (Walker *On Nyctalopia*.) The disease prevails chiefly among the lumberers in the remote backwoods of Canada. (Hind's *Labrador* i. 153.) [HEMERALOPIA.]

Night Heron. [ARDEA.]

Night Watch. A period of the night as distinguished by a change of the watch. Among the Romans the night was divided into four watches, and styled first, second, third, and fourth watches, according to the military usage, by which the guard was relieved four times during the night. The first watch began at six in the evening and lasted till nine, according to our mode of computing time; the second lasted from nine till twelve or midnight; the third from midnight till three in the morning (called *cock-crowing*); and the fourth commenced at three and ended at six, thus completing the twelve hours. The Jews originally divided the night into three watches; but at a later period they adopted the Roman division of the night, which is frequently referred to in the New Testament.

Night-jar. The name of a remarkable British bird, the type of the genus *Caprimulgus*, distinguished by the wide gape of its beak, whence perhaps has arisen the popular idea of its sucking the teats of cattle, and its other common name *goat-sucker*, the equivalent of which it has received in most European languages, and which Linnaeus has continued in its generic designation. It is scarcely necessary to remark that the structure of the bill renders the act of sucking impracticable in the night-

NINE-POINTS CIRCLE

jar or in any other bird. The genus *Caprimulgus* is characterised by a wide and deeply-cleft beak, armed with strong bristles, and capable of engulfing the larger insects; the nostrils placed at its base are like small tubes; the wings are lengthened; the feet short, feathered to the toes, which are connected together by a membrane at their base; the claw of the middle toe is commonly pectinated at the base. The night-jars are most active, and hunt their prey in the dusk; they have the same light and soft plumage as other nocturnal birds. Our common species (*Capr. europæus*) is remarkable for the loud sound it emits, like the burr or jarring of a spinning-wheel.

Nightingale (A.-Sax. nihtegale; Mr. Wedgwood connects the last syllable with the Lat. gallus). A migratory species of Passerines, and the sweetest of song-birds; the type of the sub-genus *Luscinia*, which is more closely allied, according to Mr. Blythe, to the thrush family, than to the fauvettes (*Curruidae*), among which it is placed by Cuvier. The males of the nightingale reach the southern counties of England sometimes in April, but more commonly not till the beginning of May; the females do not arrive till a week or ten days after the males. Migrating from the south, they visit this country for the purpose of breeding, and the famed song of the male is his *lore chant*, and ceases when his mate has hatched her brood. 'Vigilance, anxiety, and caution now succeed to harmony; and his croak is the hush, the warning of danger and suspicion, to the infant charge and the mother bird.' If by accident his mate be killed, the male resumes his song; and will continue to chant very late in summer unless he can attract, as he commonly soon does, another female. The nightingale feeds chiefly on the larvae of insects, which abound at the season of its arrival in this country. The nest is built near the ground; the eggs are four or five in number, of a uniform dark brown colour: the young are excluded in the month of June, and are ready to accompany the parents in their southward migration in the month of August.

Nightmare. [EPHIALTES; INCUBUS.]

Nightshade. [DULCINARA; BELLADONNA.]

Nigrine (Lat. niger, black). The reddish-brown or black varieties of titaniferous iron, from Transylvania. It occurs in pebbles and in square translucent prisms which exhibit a blood-red colour at the edges.

Nilometer. An instrument, similar to our tide gauges, for measuring the rise of the Nile during the periodical floods. It is erected on the island of Er-Rôdah, and consists of a graduated pillar upon which the height of the water is read off. The pillar stands in a kind of well which communicates with the river.

Nimbus (Lat.). In Painting and Sculpture, a circular disc round the heads of divinities, sovereigns, and saints. [AUREOLA; GLORY.]

Nimbus Cloud. In Meteorology. [CLOUD.]

Nine-points Circle. [CIRCLE, SIX POINTS.]

NINTH

Ninth (Ger. *neunte*, Lat. *nonus*). In Music, one of the dissonant intervals, being the ninth from the fundamental or an octave above the second, with which, however, it is not to be confounded, as its harmonial and contrapuntal treatment is different.

Ninsin. The French name of the Ginseng, *Panax quinquefolium*, the root of which is sometimes called Ninsin Root.

Niobe (Gr. *Νιόβη*). In Mythology, a daughter of Tantalus, married to Amphion, king of Thebes. Proud of her children, she provoked the anger of Apollo and Artemis, who slew them all: her grief turned her into stone. (Soph. *Electr.* 151.) This fable is the subject of the beautiful group in the tribune at Florence, known by the name of *Niobe and her Children*. Some antiquaries attribute it to Scopas: Winkelman inclines to believe it the workmanship of Praxiteles.

Niobium. A metallic element, discovered in Bavarian Tantalite by Rose. It is probably identical with Columbium discovered in 1801 by Hatchett in a mineral called Columbite, found in North America.

Nippers. In Sea language, small ropes for attaching the messenger to the cable.

Nisi Prius (Lat.). In Law, a term originating in a legal fiction. When the pleadings in a cause in one of the superior courts of common law [PLEADING] were concluded, and an issue of fact was raised between the parties, the issue was appointed, by the entry on the record or written proceedings, to be tried, by a jury from the county wherein the cause of action arose, at Westminster, *unless before* (*nisi prius*) the day appointed the judges of assize should have come to the county in question, which in practice they always did, in the ordinary course of their circuits; and the causes were tried before them accordingly by virtue of their commission of *nisi prius*, which empowers them to try all questions of fact issuing out of the courts of Westminster that are then ripe for trial by jury. Since the Common Law Procedure Act 1852, the *nisi prius* proviso, as it was called, has been disused, and the trial now takes place on circuit as a matter of course. Causes triable at *nisi prius* in London or Middlesex are tried at the London or Westminster sittings, held in and after every term. [COURTS, SUPERIOR.]

Nitraria (Lat. *nitrum*, *nitre*). This genus of *Malpighiaceae* from Central Asia and Northern Africa, consisting of thorny shrubs with fleshy leaves, is said to yield, in the species called *N. tridentata*, the lotus-tree of the ancients. [LOTUS-TREE.]

Nitrates. Salts of the nitric acid. [NITRE.]

Nitratine or Chili Saltpetre. A native nitrate of soda covering large areas on the borders of Chili and Peru, and also in Bolivia; sometimes to a depth of several feet.

Nitre (Lat. *nitrum*, Gr. *νίτρον*). *Nitrate of potassa*; *saltpetre*. This salt (KO_3NO_3) consists of 54 nitric acid + 47 potassa; its equivalent, therefore, is 101. It is spontaneously

NITRE

generated in the soil, and crystallises upon its surface in several parts of the world, especially in India, whence nearly the whole of the nitre used in Britain is derived. The cause of its formation is not well understood; it is probably connected with the oxidation of ammonia. The greater part of the rough nitre imported from the East Indies is in broken brown crystals, which are more or less deliquescent. Exclusive of other impurities, it often contains a considerable portion of common salt, which, reacting upon the nitre, sometimes induces the production of nitrate of soda and chloride of potassium; it also usually contains sulphate of lime and traces of organic matter. In Germany and France, it is artificially produced in what are termed nitre-beds. The process consists in lixiviating old plaster rubbish, which, when rich in nitre, affords about five per cent. Refuse animal and vegetable matter, which has putrefied in contact with calcareous soils, produces nitrate of lime, which affords nitre by mixture with carbonate of potash.

The loss which rough nitre sustains in refining is technically termed the *refraction*, and can only be ascertained by analysis, which frequently is somewhat intricate.

Nitre crystallises in anhydrous, six-sided prisms, usually terminated by dihedral summits. Its sp. gr. is about 2. The solubility of nitre varies extremely with temperature: at 32°, 100 parts of water dissolve 13.2 of salt; at 77°, 38 parts; at 132°, 97 parts; at 176°, 169 parts; and at 212°, 246 parts. During the solution of 1 part of powdered nitre in 5 of water, the temperature sinks from 50° to 35°. It is insoluble in pure alcohol. The crystals of nitre, though the salt is anhydrous, generally contain interstitial water; so that they appear moist when powdered, and lose weight on drying. The taste of nitre is cooling and peculiar.

At a temperature of about 600°, nitre fuses without undergoing change of composition, and congeals on cooling. Sometimes it is cast into small balls or cakes, called *sal prunella*. At a red heat, nitre is slowly decomposed; and highly heated in an earthen retort, or gun-barrel, it affords oxygen gas, mixed with a portion of nitrogen. In this decomposition, the nitre is first converted into *hyponitrite of potash*, which is somewhat deliquescent; potash is the final result.

Nitre is rapidly decomposed by charcoal at a red heat, and the results are carbonic oxide and acid, nitrogen, and carbonate of potash, formerly called *nitrum fixum* and *white flux*. These mixtures of nitre and charcoal form the basis of a variety of compositions used for fireworks, the rapidity of the combustion being modified by the relative proportion of the charcoal. When phosphorus is inflamed upon nitre, a vivid combustion ensues, and a phosphate of potash is formed. Sulphur sprinkled upon hot nitre burns, and produces a mixture of sulphate and sulphite of potash, formerly employed in medicine under the name of *polychrest salt*. Many of the metals, when

NITRIC ACID

in filings or powder, deflagrate and burn when thrown on red-hot nitre.

For the use of nitre in GUNPOWDER, see that article.

Nitre has sometimes been mistaken for Glauber's salt, and, when taken in the quantity of half an ounce or an ounce, it acts as a powerful poison. In such cases the stomach should be evacuated as rapidly as possible, and the symptoms of spasm relieved by opiates. In doses of 5 to 15 grains it is diuretic and diaphoretic.

Nitrate of soda crystallises in rhombic crystals; hence termed *cubic nitre*. It is found plentifully in Chili and Peru, and is imported from America. It is used as a manure and as a source of nitric acid, but, being slightly deliquescent, it cannot be employed in the manufacture of gunpowder.

Nitric Acid. (NO_3). This acid is a compound of 1 atom or equivalent of nitrogen = 14, and 5 of oxygen (8×5) = 40; hence its equivalent in the dry or anhydrous state is $14 + 40 = 54$. As it usually occurs in the liquid state, it is a compound of 1 equivalent of dry acid, 51, and 2 of water (9×2), 18; hence the equivalent of the liquid acid is 72. It is commonly known in commerce under the name of *aqua fortis*, and is prepared by distilling a mixture of sulphuric acid and nitrate of potash, or of soda. It is commonly yellow, or orange coloured; but it may be deprived of nitrous acid, which occasions this colour, by heat, and it then becomes colourless. It is intensely corrosive and sour, fumes when exposed to air, and has a specific gravity of 1.50 when in its utmost state of concentration. It boils at 248° , and freezes at -50° . It is a powerful oxidising agent, and is decomposed with more or less rapidity by almost all the metals, and acts intensely upon most organic bodies, imparting to them a yellow tinge.

The salts which it forms are called *nitrates*; they are all soluble in water; they are decomposed by heat, and, when mixed and gently heated with sulphuric acid, they evolve nitric or nitrous acid.

The composition of nitric acid was first synthetically demonstrated by Cavendish in 1786. He produced it by passing electric sparks through a mixture of 7 volumes of oxygen and 3 of nitrogen, a result verified by Faraday, in reference to the presence of traces of nitric acid in the rain of thunder-storms.

Anhydrous nitric acid was discovered by Deville in 1849, who obtained it by passing dry chlorine over dry nitrate of silver: it is a colourless crystalline solid, very unstable, and having a strong affinity for water.

Commercial nitric acid is generally contaminated by sulphuric and hydrochloric acids. When pure, no white cloud is produced in the diluted acid by a solution of nitrate of baryta, or nitrate of silver.

Nitric Oxide. (NO). This gas was first discovered by Hales, and more accurately studied by Priestley. It is obtained during the action

NITROGEN

of nitric acid diluted with about two parts of water upon metallic copper; it is copiously evolved, and may be collected over water. 100 cubical inches weigh between 32 and 33 grains; its density, therefore, compared with air, is 1.037. It is easily recognised, as it forms orange-coloured fumes whenever it escapes into the air or comes into contact with oxygen, so that this gas and oxygen are excellent tests of each other's presence. It consists of equal volumes of nitrogen and oxygen, or of 1 equivalent of nitrogen and 2 of oxygen; hence it is termed a binoxide or deutoxide of nitrogen. The respective weights of its components, therefore, are 14 nitrogen + 16 oxygen, and the equivalent of the gas is 30.

Nitrites. Salts of the *nitrous acid*.

Nitro-calcite. Native nitrate of lime. It occurs as an efflorescence upon old walls and on calcareous rocks in the form of silky tufts, with a sharp and bitter taste.

Nitro-magnesite. A native hydrated nitrate of magnesia, found with Nitrocalcite, which it resembles in colour and other characters.

Nitrogen (Gr. *nitron*; *νετρον*, I produce).

A simple gaseous body (represented by the symbol N), which forms a constituent of the atmosphere and of nitric acid, and which, being unrespirable, has also been termed *azote*: from *a*, privative, and *ζωη*, life. It was identified as a peculiar gas by Dr. Rutherford in 1774, in which year it was also shown by Lavoisier to be one of the components of atmospheric air. It may be obtained, when not required absolutely pure, by burning a piece of phosphorus in a jar full of air inverted over water. The phosphorus during its combustion combines with the oxygen of the air to form phosphoric acid, which is dissolved by the water, and the remaining element of the air, namely the nitrogen, remains. Pure nitrogen may be obtained as follows: Place some *pyrogallic acid*, moistened with a strong solution of caustic potash, in a porcelain capsule floating on a water-bath, and invert a jar of air over it; the oxygen of the air will be more or less rapidly absorbed according to the quantity of the pyrogallic acid and the strength of the potash solution. In this case the carbonic acid, as well as the oxygen of the atmospheric air, is absorbed, so that the residuary nitrogen retains only aqueous vapour, which may be abstracted by any of the usual processes. Nitrogen is also obtained by passing air over shavings of metallic copper, heated to redness in a porcelain tube; the oxygen is retained by the copper, and the resulting nitrogen may be deprived of traces of carbonic acid by passing it through caustic potash, and of moisture by finally transmitting it over fused chloride of calcium. The decomposition of a solution of ammonia by the action of chlorine, has also been resorted to as a means of procuring nitrogen; in this operation the hydrogen of the ammonia combines with the chlorine to form hydrochloric acid, and the nitrogen of the decomposed portion of the ammonia is set free. If the ammoniacal so-

X X

lution be very concentrated, the bubbles of chlorine as they pass into it often produce flashes of light and slight explosions, and care should be taken to avoid excess of chlorine, which might tend to the formation of the dangerously explosive compound known as *chloride of nitrogen*. Nitrogen is a colourless, inodorous, and tasteless gas, not absorbed by water, and having no action on vegetable colours. It extinguishes all burning bodies, and is itself unflammable. It is a little lighter than atmospheric air, 100 cubic inches weighing 30.16 grains. Its equivalent is 14, and it combines with oxygen in 5 proportions, giving rise to the following compounds:—

	By volume	By weight	Equiv.	Symb.
	N.	O.	N.	O.
1. Nitrous oxide . . .	100 + 50 = 14 +	8 = 22 = NO.		
2. Nitric oxide . . .	100 + 100 = 14 + 16 = 30 = NO.			
3. Hyponitrous acid . .	100 + 150 = 14 + 24 = 38 = NO.			
4. Nitrous acid . . .	100 + 200 = 14 + 32 = 46 = NO.			
5. Nitric acid . . .	100 + 250 = 14 + 40 = 54 = NO.			

Nitrogen is an important component of many organic substances, and is remarkable as one of the constituents of most of the fulminating compounds, such as fulminating gold, silver, and mercury, and the chloride and iodide of nitrogen. Ammonia contains 82 per cent. of nitrogen. It forms *nitrides* with a few of the metals.

Nitrohydrochloric Acid. *Nitromuriatic acid*. The mixture of nitric and of hydrochloric acid; formerly called *aqua regia*, from its solvent power over gold, the *king* of the metals. When these acids are mixed, chlorine and nitric oxide are evolved, and a chloride of gold is formed.

Nitropicric Acid. A synonym of CARBAZOTIC ACID.

Nitroprussides. When nitric oxide is passed through an aqueous solution of hydroferricyanic acid, one of the products is *hydro-nitroprussic acid*, the formula of which is H_2, Fe, Cy, NO_2 ; it forms a series of salts, discovered by Dr. Playfair (*Philosophical Transactions* 1848). One of the most characteristic of these is the *nitroprusside of sodium*: $Na_2, Fe, Cy, NO_2 + 4Aq$. It forms red prismatic crystals, the solution of which, when exposed to light, deposits Prussian blue, and evolves nitric oxide; when an alkaline sulphide is added to it, even in a most diluted state, it assumes a deep and characteristic purple colour, which, however, soon disappears.

Nitrosaccharic Acid. By the action of sulphuric acid on gelatine a peculiar saccharine matter is formed (*glycosine*), which combines with nitric acid, and forms a crystallised acid designated as above.

Nitrosulphuric Acid. A compound of nitric oxide and sulphurous acid; only formed in the presence of bases. Its salts are easily decomposed, and the acid itself cannot be obtained in a separate form. This term has also been applied to an acid resulting from the mixture of one part of nitre with eight or ten parts of sulphuric acid, and proposed by Mr.

Keir as a useful agent for separating the silver from the copper of old plated goods. At a temperature of about 200° it dissolves silver, while it scarcely acts upon copper or lead, unless diluted, or at higher temperatures.

Nitrous Acid. (NO_2) *Hyponitric acid*. *Peroxide of nitrogen*. When two volumes of nitric oxide and one of oxygen are mingled in an exhausted glass globe, they form a dense orange-coloured vapour, which may be liquefied at 20°, and crystallises at 16°. Its elements are so condensed that 1 volume of nitrogen and 2 of oxygen form one volume of nitrous acid vapour, the specific gravity of which is 3.17. The presence of this vapour renders nitric acid red and fuming, in which state it is commonly termed *nitrous acid*.

Nitrous Oxide. (NO) *Protoxide of nitrogen*. This gas was discovered by Priestley in 1776, who called it *dephlogisticated nitrous air*, but its properties were first fully investigated by Davy in 1800. It may be obtained by carefully heating pure nitrate of ammonia, which salt is thus resolved into nitrous oxide and water. This gas is liquefied under a pressure of 50 atmospheres, and solidified at a temperature of 150° below 0°. The specific gravity of this gas is 1.5, and its equivalent 22 (14 + 8). An ignited taper burns brilliantly in it, the flame being surrounded by a purplish halo.

Nitrous oxide is a narcotic poison, and when breathed, destroys life. It may, however, as was first shown by Davy, be taken by a human being in a small quantity; and if the lungs be emptied before it is inhaled, it rapidly causes a peculiar species of intoxication, manifested at first by unsteadiness of gait, and subsequently by violent muscular exertion. There is a brilliant flow of ideas, with, generally speaking, a great disposition to pugnacity. From the pleasing kind of delirium which it produces, it has been called *laughing* or *paradise gas*. When breathed, it is rapidly absorbed into the blood, and produces a great change in that fluid—manifested by a dark-purple colour of the lips, and by a livid or pallid appearance of the face. Some have fallen down at once powerless, but the greater number are thrown into a state of violent excitement. In general the exhilarating effects pass off in from five to ten minutes, and, with the exception of some prostration of strength and slight headache, no injurious symptoms follow. But in certain cases, probably from idiosyncrasy, the respiration of the gas has been attended with severe headache, giddiness, double vision, and even some delirium, with a feeling of weakness from exhaustion, lasting for several days.

Nizam. The title of one of the native sovereigns of India. It is derived from Nizam-ul-Mulk, who in the beginning of last century obtained possession of the Mohammedan conquests in the Deccan; his successors in the sovereignty having assumed his name as their title of dignity, which they have retained to this day.

NOBILITY

Nobility (Lat. nobilitas). A general name for the highest orders of society. [ARISTOCRACY.] In most countries the term has denoted primarily an hereditary aristocracy. At Rome as in Athens [EUPATRIDÆ] the nobles, or patricians, formed strictly a caste, as distinguished from the plebs, all curule offices being in the hands of the former, and no right of intermarriage (jus connubii) with the privileged class being allowed to the latter. On the privileges of this order, which extended to the exclusive right of suffrage (jus suffragii), the plebeians gradually encroached with success, and all plebeians who had filled a curule office came to be regarded as belonging to the class of nobles. These *novi homines*, or new men, imparted fresh life to an aristocracy which, if it had remained exclusive, must soon have become extinct. Thus an order of Nobiles was formed which stood out in contrast with the Ignobiles; but while they had no legal privileges, they combined with the old patrician families to keep all offices of state as much as possible within the circle of their own order. They had, however, the external distinction of the *jus imaginum*, or the right of setting up the images or busts of their ancestors. [NOVI HOMINES; PEERAGE.]

Noble. An English coin of the middle ages, value 6s. 8d., current in the reign of Edward III. According to Knighton, the *rose noble* was a gold coin in use about the year 1344.

Noctiluca (Lat. literally *shining by night*). A term applied by Boyle and some of the older chemical philosophers to phosphorus.

Nocturn (Lat. nocturnus, *nightly*). An office consisting of psalms and prayers, celebrated in the Roman Catholic church at midnight. It is said to have been introduced into the West by St. Ambrose. It now forms part of the service of matins.

Nocturnal. A tribe of Raptorial birds, including those which fly by night, and have the eyes directed forwards: also a family of Lepidopterous insects, which, in like manner, are active chiefly in the night season.

Nodal Points or Nodal Lines. A vibrating chord can spontaneously divide itself into any number of aliquot parts, each of which will vibrate separately as if it were fixed at its two extremities and formed a separate chord. The points of separation between two such contiguous parts, which do not participate in the vibration of either the one or the other, but remain at rest, are called *nodal points*. In like manner, when elastic plates are put into a state of vibration, the molecules separate themselves into parcels which vibrate independently of each other; and the lines of separation thus formed, or lines of repose in which no vibration takes place, are called *nodal lines*. [VIBRATION.]

Noddies or Boobies. A group of marine birds of indistinct specific identity, belonging to the genus *Sula*, comprising the Gannets. The term is sometimes restricted to the large brown bird (*Sula fuscus*) which is found in warm or temperate climates throughout the globe. The

NODES

disinclination of these birds to fly at the approach of man, and the ease with which they can be knocked down with sticks, has led to the singular name applied to them by Dampier, De Gennes, and subsequent travellers.

Node (Lat. nodus, a knot). In Botany, a point situated upon the axis of a plant, whence a leaf or leaf-bud originates.

Node. In Geometry, this word is synonymous with *double point*. In the theory of curves, the term *node*, however, is usually applied only to a double point, at which the two tangents are real and distinct; when these tangents coincide, the node becomes a *cusp* or *stationary point*, and when both tangents are imaginary, it receives the name of *conjugate* or *isolated point*. In the theory of surfaces, nodes are also called *conical points*, since the surface is there cut in *three consecutive points* by the generators of a quadric cone. [CONICAL POINT.] When this cone breaks up into two planes, the node is termed a *bipolar node*, and when these planes coincide, a *unipolar node*. A *proper node* is one at which the cone in question does not so break up. A *nodal line* on a surface is a curve every point of which is a node.

Node. In Surgery, a hard tumour upon a bone, which creates considerable pain, and often is attended by caries or necrosis. They are most common upon the tibia and bones of the head and fore-arm, where they are thinly covered by flesh.

Nodes. In Astronomy, the two points in which the orbit or the equator of a planet intersects the plane of the ecliptic. The point in which the centre of a planet passes from the south to the north side of the ecliptic is called the *ascending node*, and in astronomical computations is usually indicated by the symbol Ω ; the opposite point, or that in which the planet passes to the south side of the ecliptic, is called the *descending node*, and is indicated by γ . The straight line which joins these two points, formed by the intersection of the plane of the planet's orbit with the plane of the ecliptic, is called the *line of nodes*. The nodes of the lunar orbit were anciently called the head and tail of the dragon.

The position of the nodes on the ecliptic is one of the elements by which the situation of the plane of an orbit in space is defined; in fact, it is easy to see that, if the position of the line of the nodes, and also the inclination of the orbit to the ecliptic, be known, the position of the plane of the orbit is entirely determined. The two nodes being distant 180° , it is only necessary to indicate the position of one of them: the longitude of the ascending node, or its distance from the first point of Aries, is the element used by astronomers. In all the planetary orbits the line of the nodes is variable, having a retrograde motion from east to west in respect of the fixed stars, but so slow that it amounts only to a few seconds in a year. The regression of the moon's nodes is very considerable, as it completes a revolution in

NOËL

about nineteen years. [MOON.] This retrograde motion of the nodes of all the planets is a necessary consequence of their mutual attractions. For the positions and variations of the nodes of the different planets, see **PLANET**. The nodes of a planet's equator are one of the elements of the planet's rotation, the inclination of the axis and time of rotation being the others.

NOËL. The French name of Christmas-day, derived, it is said, from *dies natalis* (Lat. *birthday*).

NOETIANS. In Ecclesiastical History, a sect so called from Noetus, an Ephesian, the master of Sabellius. They acknowledged only one Person in the Divinity; and, consequently, were accused of maintaining that God the Father had suffered on the cross. [PATRIPASSIANS.]

NOG. The bolt or tree-nail which secures the heel of each shore employed in sustaining a ship in dock or on the slip.

NOGGING. In Architecture, brickwork carried up between upright pieces or quarters, introduced in order to give the wall or partition greater lateral stiffness and strength.

NOGGING PIECES. In Architecture, horizontal pieces of timber fitting in between the quarters, to which they are nailed in a brick nogged partition, which, by their resistance to lateral motion, they serve to steady and strengthen.

NOLANACEAE (Nolans, one of the genera). A natural order of perigynous Exogens of the Echioal alliance, consisting of herbaceous or shrubby plants, natives of South America. They are distinguished by their straight inflorescence, regular flowers, free stamens, five nuts, and a naked stigma. None of them are of any known use, but the genus *Nolana* affords several ornamental annual flowers.

NOLI ME TANGERE (Lat. *touch me not*). In Surgery, a disease of the skin, commencing with small ulcerations which eat away the part. These ulcerations sometimes affect the cartilage of the nose, which is destroyed by their progress; almost all applications rather increase than stop the ravages of the disease, which has received the name of *lupus* (Lat. *wo'f*) from its devouring qualities.

NOLI-TANGERE. In Botany, the plant called Touch-me-not, tho. *Impatiens Noli-tangere* of systematists.

NOLLE PROSEQUI (Lat.). In Law, an acknowledgement or agreement by the plaintiff in a suit that he will not further prosecute it, either as to the whole or a part of the cause of action (for instance, on the defendant's demurring to one count in a declaration, the plaintiff may enter a nolle prosequi as to that count, and proceed to trial on the other counts), or as to one or more out of several defendants.

NOMADES (Gr. *νομάδες*; from *νόμος*, *pasture*). Tribes of men without fixed habitation. The nomades of ancient times were generally tribes devoted to pastoral pursuits; for the Greeks and Romans knew of no races subsisting wholly

NOMINALISTS

by the chase. The principal nomadic tribes of antiquity were those of Southern Russia and the interior of Asia, from whom sprang, in the decline of the Roman empire, many of the tribes which overran Western Europe; and, at a later era, those which conquered empires in Western and Southern Asia. The vast regions of Mongolia are inhabited by nations which still retain their wandering habits. [TURANIAN LANGUAGES.]

NOME (Gr. *νόμος*; from *νέμω*, *I divide*). The Greek name for the provinces into which Egypt was anciently divided. According to Diodorus Siculus, the division into nomes was made by Sesostris, whom some modern writers consider as identical with the Rameses II. of the monuments; but such statements refer to a time of which we have no historical knowledge. There were thirty-six nomes, which, in the time of Strabo, were thus divided—ten in the Thebaid, sixteen in the Heptanomis, or intermediate district (which, according to its name, probably consisted in earlier times of seven only), ten in the Delta. This division was not materially altered until the latest age of the Roman government. (D'Anville, *Mémoires sur l'Égypte*; Wilkinson's *Manners and Customs of the Ancient Egyptians*, vol. ii.)

NOMENCLATOR (Lat.). An officer employed by the candidates for the great state offices of Rome, to accompany them through the streets and whisper to them the names of such citizens as they might meet, in order that they might then address them by name, and canvass their votes. It is derived from Lat. *nomen*, and the old word *calo*, *I call*.

NOMENCLATURE. A term originally applied to a catalogue of the most ordinary words in any language, with their significations, &c. But, in a more special sense, this term is employed to denote the language peculiar to any science or art: thus we speak of the nomenclature of chemistry, botany, &c.

NOMINAL PARTNER. In Law, one who allows his name to be used as having an interest in a partnership in which he has in fact no concern, and thereby subjects himself to the liabilities of the partnership, 'as against all the rest of the world.' [PARTNERSHIP.]

NOMINALISTS. A term originally applied to a scholastic sect which arose in the eleventh century. Its founder was John Roscelin, a churchman of Compiègne, who asserted that general terms have no corresponding reality either in or out of our minds, being, in truth, words, and nothing more (*flatus vocis*). [LOGIC.] This doctrine naturally excited great consternation among the schoolmen, with whom, hitherto, all that was real in nature was conceived to depend on these general notions or *essences*. Its promulgator underwent much persecution for his opinions, and was ultimately compelled to retract them, as inconsistent with the doctrine of the Trinity, as it was then stated. He found, however, an able successor in the person of Peter Abelard, who attracted numerous disciples by his dialectical skill and

NOMINATIVE CASE

eloquence, and, with his followers, whom he led in a body to Paris, was the occasion of founding the celebrated university of that city. After his death the ancient realism was restored to its supremacy; nor do we meet with a nominalist until the thirteenth century, when William of Ockham revived his doctrines under some modifications. The last-mentioned philosopher may, in fact, with greater justice, be styled a conceptualist, as he distinctly stated the formation of general terms to depend on the conditions of thought, and hence to possess a species of subjective reality, as the sign or indication of an actual process of thought, though they were neither distinct objects of consciousness nor realities in nature. Those who hold either of the latter theories are realists. The controversy is one which has excited great attention among modern philosophers. Of these, Hobbes and Dugald Stewart may be considered strict nominalists, while Locke and Dr. Thomas Brown style themselves conceptualists. There are, however, expressions in Locke's writings which would rather stamp him as a realist, under the former of the two modifications which we have given above. [SCHOLASTIC PHILOSOPHY; THOMISTS; SCOTISTS.] (Hallam's *Literature of Europe in the Fifteenth, Sixteenth, and Seventeenth Centuries*, part i. ch. iii. § 67 &c.; Brucker's *Historia Critica Philosophiæ*.)

Nominative Case. In Grammar, that form of a noun which names or designates a substance *absolutely*, or without relation to any other substance.

Monocanon (Gr. νόμος, *law*, and κανών, *canon* or *rule*). In Ecclesiastical Law, a work in which canons of the church, and imperial laws touching the same subjects, are collected and compared. The first was made by Joannes Scholasticus (A.D. 551). The most celebrated was that of Photius, patriarch of Constantinople.

Nomophylaces (Gr. νομοφύλακες, *guardians of the law*). At Sparta and elsewhere, magistrates whose duty it was to see that the laws were rightly administered and obeyed. At Athens, they were merely inferior police officers who had to keep order in the public assemblies; but some think that no officers so called existed there till the time of Demetrius Phalereus.

Nomothetes (Gr. νομοθέται, *legislators*). An office instituted probably by Pericles. A certain number of citizens, chosen out of the 6,000 dicasts, were lotted off to sit together on special occasions, to decide on propositions for introducing new laws, &c. (Grote's *History of Greece*, part ii. ch. xlvi.)

Non Compos Mentis (Lat.). In Law, a person not legally responsible for his acts in consequence of mental deficiency. [LUNACY.]

Non est Inventus (*he is not found*). In Law, the formal Latin words anciently used in the sheriff's return to a writ of capias, that the defendant was not to be found within his bailiwick.

NON-RESISTANCE

Non Prosecutor (Lat.) or **Non Pro.**, **Judgment of.** This is a final judgment for costs, which may be signed by the defendant if the plaintiff in an action at law neglects to prosecute it. The corresponding course in a suit in equity is to move to dismiss the bill for want of prosecution.

Non-commissioned Officer. In the Army, one who, while he is not commissioned as an officer, holds an appointment by virtue of which he exercises authority over the private soldiers. Such are sergeant-majors, quartermaster sergeants, and sergeants. A non-commissioned officer can be reduced to the ranks by sentence of court martial or order of the colonel or other officer commissioned as *commandant* of his regiment; but so long as he holds his rank he can receive no minor punishment.

Non-feasance. In Law, the offence of omitting what ought to be done.

Non-naturals. A term applied by the old physicians to things which, although necessary to life, do not form a part of the living body; such as air, food, sleep, &c.

Non-obstante (Lat. *notwithstanding*). In old English Law, a license from the crown, usually conveyed by a clause in letters patent, &c., to do something which by common law might be done, but was restrained by Act of Parliament. Such license could of course only rest on high doctrines of prerogative, and were the means by which James II. endeavoured to carry into execution his celebrated *dispensation*, annulled by 2 Wm. & Mary c. 2.

Non-obstante Verdicto, Judgment. When the defence upon the record is not a legal defence to the cause of action, and the defendant obtains a verdict, the plaintiff may in some cases obtain leave to sign judgment notwithstanding the verdict. The defendant's course in a similar case is to move in arrest of judgment.

Non-resistance, The Doctrine of. In Politics, that doctrine which inculcates the unlawfulness, on religious grounds, of resistance by force to the commands of a prince or magistrate. This is strongly laid down in many books of the New Testament, and especially by St. Paul (Rom. xiii.). In its ordinary acceptation, the doctrine is understood to enforce the duty of obedience to the lawful commands of magistrates. But, in that peculiar sense which is attached to it in English constitutional history, it means unqualified obedience to every command, especially of the prince or supreme magistrate, whether lawful or not; and consequently it condemns all forcible opposition even to tyranny or usurpation. But the advocates of non-resistance, in this extended sense, do not appear to have ever contended that it applied to commands of inferior magistrates in the same sense and degree as to those of the highest: they therefore supposed a peculiar sanctity in the person and office of the sovereign which no other officer possessed; and thus combined the doctrine of

divine right with that of passive obedience or non-resistance. These doctrines are plainly laid down in the homilies of the church of England; in which, in the phrase of Bolingbroke (*States of Parties*), they *skulked* until the reign of James I. (See especially the Homily *On Wilful Disobedience and Rebellion*.) But in that reign they were more generally avowed by the learned and loyal; and in 1622 the university of Oxford sanctioned them by a solemn decree. The events which led to and followed the great rebellion naturally led men's minds to pay greater attention to the speculative part of politics; and, while Hobbes was framing a theory of absolute monarchy on the principle of the social contract, a different class of reasoners arrived at the same result through a peculiar interpretation of Scripture. Sir Robert Filmer (especially in his *Patriarcha*), Bishop Sanderson, and others, made the regal power originate in the patriarchal; and endeavoured to prove that all other forms of government, being unrecognised by Scripture, were usurpations. Dean Sherlock, the ablest writer of the school of divine right (*Case of Resistance to Supreme Powers*, 1684), endeavoured to prove the absurdity of the theory of the social contract, and to show from Scripture the unlawfulness of resisting any command, even of a usurping power. In answer to these reasoners Locke wrote his *Essay on Government*, in which he seeks to confute the arguments for unqualified non-resistance, by showing that Scripture and reason make no distinction between inferior and superior magistrates, and reducing his opponents to the absurdity of affirming that any command, however extravagant, of the lowest magistrate, must be obeyed. In 1683, the university of Oxford pronounced its second decree in favour of the tenets of divine right and non-resistance. But the current of court opinion changed at the Revolution. The doctrine of non-resistance was almost proscribed; but maintained by the non-jurors, who professed to *obey* the usurping government, while they refused to *recognise* it. In 1709 it was preached by Sacheverell, with the apparently inconsistent result of a riot. His sermon, together with the Oxford decree, was burnt by order of the House of Lords. But the doctrine has been within these few years asserted by the high church party. (Dr. Pusey's *Sermon on the 5th of November*, 1838.)

Nonæ et Decimæ (Lat.). In Ecclesiastical Law, the contributions of tenants of the church were anciently so called: the *nonæ*, or ninth part, standing for a species of rent, the *decimæ* for the tithe due to the church.

Nonage. In Law. [INFANT; MINORITY.]

Nonagesimal (Lat. *nonagesimus*, the *ninetieth*). In Astronomy, the *ninetieth* degree of the ecliptic, reckoned from either of the points in which it is intersected by the horizon. It is therefore the highest point of the ecliptic at any instant, and its altitude is equal to the distance of the pole of the ecliptic from the zenith. The nonagesimal is used in calculating the parallax of the moon.

Nonagon. A plane rectilinear figure having nine sides. [ENNAGON.]

Nonconformists. A general term under which all the religious communities which do not conform to the liturgy of the established church of England may be comprehended, but usually confined to Protestant Dissenters. Historically, it belongs more properly to the large body of clergy who, at the Restoration, refused to subscribe to the Act of Uniformity, and were in consequence ejected from their benefices on St. Bartholomew's day, 1662. This Act was first promulgated by Elizabeth, and required all the clergy to use the Book of Common Prayer, and inflicted severe penalties upon any one who should be convicted of speaking or preaching against it. The Act of Charles II. contained provisions still more strict, enjoining every beneficed person not only to use the book, but to declare his assent and consent to every part of it: and enacting that unless this were done on a certain day he should be, ipso facto, ejected. Other declarations were also to be subscribed; as, 'That it is unlawful to take arms against the king on any pretence whatsoever;' 'That no obligation from the covenant lies upon himself or any other person.' It is said that two thousand persons resigned their preferments in consequence; and even after this their party was subjected to the further infliction of the Conventicle Acts, which forbade more than five persons besides the family to assemble together in any house for religious worship; and the Five Mile Act, which subjected to penalties and imprisonment any nonconformist clergyman who should take up his residence within five miles of any corporate town, or other place where he had been minister. [DISSENTERS.]

Nones (Lat. *Nonæ*). In the Calendar, one of the three divisions of the Roman month, and so called because they fell on the *ninth* day, reckoned inclusively, before the *ides*. In the months of March, May, July, and October, the *ides* fell on the 15th day of the month, and the *nones*, consequently, on the 7th. In the other months, the *ides* were on the 13th day, and the *nones* on the 5th. [CALENDAR; CALEND; IDES.]

Nonius. A name frequently given to the *VERNIER* (a useful contrivance for subdividing the divisions of graduated arcs or scales into minute parts), from an erroneous idea that it was invented by Pedro Nunez, or Nonius, a Portuguese, who lived in the early part of the sixteenth century. The contrivance employed by Nonius was widely different from the *vernier* now universally used. It consisted in describing within the same quadrant 45 concentric arcs, dividing the outermost into 90 equal parts, the next into 89, the next into 88, and so on, the innermost being consequently divided into 46 only. With this instrument the observed altitude of an object could be read off on the outermost arc only to degrees, but the fractions were obtained in the following

manner: the plumb-line, or movable index, must intersect one of the concentric arcs at, or very near, a point of division. Now, it is evident that the number of parts read off at this point must be in the same proportion to the degrees and fractions of a degree intercepted on the outermost arc, as the number of parts into which the arc containing the point is divided, is to 90°. The division read off being therefore multiplied by 90, and divided by the number of parts in the arc, gives the observed altitude to fractions of a degree. Thus, if the plumb-line intercept 25 parts exactly on the arc in which the number of parts is 78, the angle measured will be 28°46': the fraction is easily converted into minutes and seconds. Nonius supposed that this artifice was known to Ptolemy. It was adopted by Tycho Brahe; but soon abandoned by him for the method of diagonal divisions, in consequence of the difficulty of dividing accurately the different arcs. (Robins's *Mathematical Tracts*, vol. ii.) [VERNIER.]

Nonjurors. In English History, that party among the clergy of the national church who refused to take the oath of allegiance to the new government after the Revolution. Eight bishops, including the primate Sancroft, with about four hundred clergy, were in consequence ejected from their benefices. Of these the most learned was Hickes, bishop of Peterborough. The ecclesiastical history of Great Britain by Jeremy Collier is written on their principles. They maintained a strict and necessary connection between the national church of England and the catholic church throughout the world; and while they denounced the special errors of the Romish branch of the church, allowed it an indefeasible precedence and authority. In politics they held the doctrines of divine right and passive obedience. The nonjurors maintained their ecclesiastical position through the greater part of the last century, their bishops continuing to ordain and consecrate; but their numbers dwindled away, and Dr. Robert Gordon, who died in November 1779 at a very advanced age, was the last in their episcopal succession. [JACOBITES; PRETENDER.]

Nonpareil. In Printing, the name of a kind of type two sizes smaller than that used in this work. It was called *nonpareil* by the old English printers. [TYPE.]

Nonsuit. In Law, the renunciation of a suit by the plaintiff. It is either adjudged, in consequence of certain neglects or delays in the prosecution of the suit, or it is voluntarily elected by the plaintiff. It is usual to call on the plaintiff, when he is unable to make out a case to support his pleadings in default of the necessary evidence and the jury are about to give their verdict, to elect, if he pleases, to abandon his prosecution and submit to a nonsuit, upon payment of costs. The effect of this is, that as a nonsuit is not, except in certain cases, a peremptory bar, he is able to bring another action afterwards for the same cause.

Judgment as in case of a nonsuit arose from the statute 14 Geo. II. c. 17, which enacted that where the plaintiff had neglected to bring the issue to be tried, the court might, unless it saw reason for allowing the plaintiff further time, give judgment for the defendant as in case of a nonsuit, which had the same force as a nonsuit, both as to costs and as to its effects on the action; but this statute was repealed by the Common Law Procedure Act, 1852, which provides that the defendant may sign judgment for his costs where the plaintiff neglects to proceed to trial, unless the time for proceeding to trial is extended by the court or a judge.

Nontronite. A hydrated tersilicate of iron, occurring in France, at Nontron, in the department of the Dordogne. It is found in small kidney-shaped masses, varying in colour from green to yellow, and with a dull lustre.

Wootth's Apparatus. A series of three glass vessels, placed vertically, for the purpose of impregnating water with carbonic acid gas. The lower vessel contains the marble and dilute acid for the evolution of the gas; the central vessel holds the water through which it is made to pass, under the pressure of the column of water in the third or upper vessel, which is closed by a heavy conical stopper, serving as a safety valve. This form of apparatus has been superseded by the comparatively modern and more effective *gasogene*.

Nopal. One of the names of *Opuntia vulgaris*. The allied species, *O. coccinellifera*, is one of the plants upon which the cochineal insect chiefly breeds, another being *Opuntia Tuna*.

Noraghe. The name of a singular class of monuments found in great numbers in the island of Sardinia, about the origin and the uses of which antiquarians are at present much divided. The noraghe are generally built upon a circular or elliptical plan, and have the form of a truncated cone; access is gained to the interior by a door situated towards the south-east, which leads to a corridor communicating with two ranges of chambers, before reaching the central tower. There are four classes of noraghe; the *simple* ones, resembling isolated towers; the *collective*, composed of several united bodies of this class; the *united*, consisting of a large enclosure in the same style of construction, usually upon the top of a hill; the *surrounded* noraghe, or those encircled by exterior works, like a kind of fortress. There are said to be as many as three thousand noraghe in Sardinia; the best account of them is to be found in Della Marmora's *Itinéraire de l'île de Sardaigne*, Turin 1860, in which the various theories as to their origin are discussed. They are probably sepulchral monuments, erected in memory of a distinguished leader or chieftain.

Norbertines. [PREMONSTRATENSIANS.]

Nordhausen Acid. A peculiar sulphuric acid, intermediate between the anhydrous and monohydrated acid, so called from the place

NORM

where it was formerly manufactured. It is generally in the form of a brown fuming liquid. It is a good solvent of indigo.

Norm. [INTEGER.]

Normal (Lat. *norma*, a rule). The normal to a curve is any perpendicular to the tangent erected at the point of contact. At every point of a curve, therefore, there are innumerable normals, all of which are situated in the *normal plane of the curve*. The most important of these normals, however, are the *principal normal*, which lies in the osculating plane, and the *binormal*, which is perpendicular to that plane and, consequently, to the two consecutive tangents which the plane contains. In plane curves, where all osculating planes coincide, the principal normal is the only one considered, so that it is not necessary to distinguish it by the term *principal*. Two consecutive normals of a *plane curve* intersect in a point which, being equidistant from three consecutive points of the curve, is the centre of the osculating circle (circle of curvature); the angle between two consecutive normals (angle of curvature) is obviously equal to the angle between the corresponding tangents (angle of contact or contingency). The normals of a curve envelope a second curve (the *evolute*), which is the locus of the centres of curvature of the original one. In non-plane curves this is not the case, for two consecutive principal normals do not intersect one another. The point, however, in which any principal normal is intersected by the next succeeding *normal plane*, is equidistant from three points of the curve, and is consequently the centre of an osculating circle. This is, in fact, the circle of absolute curvature; it lies in the osculating plane, and has its centre on the polar line. The locus of the centres of absolute curvature, therefore, is a curve on the polar developable, but it does not belong to the series of evolutes which this surface contains, since all evolutes are formed by *intersecting* consecutive normals. [EVOLUTE.]

The *normal to a surface* is the perpendicular to the tangent plane erected at the point of contact. Any plane through it is called a *normal plane of the surface*. Two consecutive normals to a surface do not, in general, intersect each other; in fact, a normal is intersected by only two of all the consecutive normals, and the normal planes which contain these intersecting normals are always at right angles to each other; they contain also the tangents to the two lines of curvature which pass through the point on the surface. [CURVATURE, LINE OF.] The methods of finding the equations of normals to curves and surfaces, are given in all treatises on the geometrical applications of the differential calculus.

NORMAL. In Botany, an adjective signifying that the ordinary structure peculiar to a family, a genus, or a species, is not departed from.

Normal School. [SCHOOL.]

Norman Architecture. [ARCHITECTURE.]

Norns. In Scandinavian Mythology, the three Fates, equivalent to the Moirai of the

NOTABLES

Greeks. [MOIRAI.] Their names were Urd, Wörand, and Skuld; or *Past*, *Present*, and *Future*. They were represented as endowed with great beauty, but of a melancholy and sombre disposition; they were consulted even by the gods, and their decrees were sure and irrevocable.

Norroy. [KING-AT-ARMS; HERALD.]

North (Ger. *nord*). In Geography, one of the four cardinal points of the horizon; that which in European latitudes is opposite the sun at midday.

North-West Passage. A channel along the northern extremity of North America, long believed to be available for commercial purposes. The existence of such a passage has been proved in various ways, and lastly by the expedition in which Franklin and his associates were lost after making their way between the termination northwards of the American land and the southern extremity of the ice of the North Polar Sea. The many expeditions organised to prove the existence of this channel were very fertile in geographical discovery, and have succeeded in showing that for commercial purposes there was no passage of the kind.

Northern Lights. The name popularly given to the *aurora borealis*.

Northing. In Navigation, the difference of latitude made by a ship in sailing northwards.

Nose (Lat. *nasus*, Fr. *nez*). The fleshy protuberance, which contains the external cartilages serving to receive the sensation of smell, is so termed in the higher vertebrate animals.

Nosean. A mineral allied to Haüyne, and named after the discoverer, R. W. Nose. It is found in rhombic dodecahedrons in the eruptive rocks of Lake Laach, near Andernach on the Rhine, and in the leucite-rock of Rieden and Volkersfeld in Prussia.

Nosing of a Step. In Architecture, the projecting rounded edges of the tread of a step; it is introduced for ornament, and also to widen the tread.

Nosology (Gr. *νόσος*, a disease, and *λόγος*). The doctrine of diseases. The term is generally applied to the classification and nomenclature of diseases, and to their general methodical arrangement. [DISEASE.]

Nostalgia (Gr. *νοσταλγία*, to be homesick). A longing to return home; a disease sometimes observed in a marked degree among the Swiss, the Highlanders, and the Irish. It is well described in Baron Larrey's works. He relates that many of the soldiers under his care were affected by it. The mental faculties early became impaired, and melancholia with severe gastric symptoms terminated the lives of his patients. Between the years 1800 and 1820 as many as ninety-seven French soldiers fell victims to the disease.

Nostrum (Lat.). Literally, *our own*; a term applied to quack medicines retained for profit in the hands of the inventor or discoverer, or of his assignee.

Notables. In French History, the deputies of the states under the old régime, appointed

and convoked on certain occasions by the king. In 1786 this assembly was summoned, 160 years after its last meeting, and proposed various reforms in different branches of the government; it again met, for the last time, in 1788.

Notacantha (Gr. *σῆρας*, the back, and *κνάρη*, a spine). The name of a family of Dipterous insects, comprehending those in which the upper part of the thorax or scutellum is armed with teeth or spines.

Notaries, Apostolical and Imperial. Public notaries appointed by the popes and emperors, in virtue of their supposed jurisdiction over other powers, to exercise their functions in foreign states. Edward II. forbade the imperial notaries to practise in England. Charles VIII. of France, in 1490, abolished both these classes of notaries, and forbade his lay subjects to employ them.

Notary or Notary Public. In English Law, one who publicly attests documents or writings, chiefly in mercantile matters, to make them authentic in a foreign country; protests foreign bills of exchange, and the like. The statutes 41 Geo. III. c. 79 and 6 & 7 Vict. c. 90 regulate the admission of notaries in England. They must have been apprenticed five years to a notary before such admission.

The name *notary*, among the Romans, appears to have signified a shorthand writer, and to have denoted originally the persons who acted in that capacity, especially at meetings of the senate. Afterwards, the *notarii* were secretaries to courts, officers, &c. In modern Europe, the notary is an officer whose attestation is necessary to the validity of certain instruments; and his duties are more or less important in different countries. In France the notary is the necessary maker of all contracts, &c., where the subject-matter exceeds 160 francs; and his instruments, which are preserved and registered by himself, are the originals, the parties retaining only copies. The presence and administration of a notary is also essential to the division of lands or goods on inheritance.

Notation, Chemical. A symbolical language employed to express the composition of substances and the changes which occur in chemical processes.

The only symbols employed by the alchemists which appear to have had a fixed meaning were the astrological signs for the metals; and even in the time of the earlier chemists, when other similar signs were added to denote new substances, symbols fulfilled no other purpose than that of convenient abbreviations for names. The first attempt to arrange such symbols in a systematic manner was a plan proposed by Lavoisier in 1782, by which he represented the quantities of substances in addition to the substances themselves. Dalton's completion (in 1804) of the discovery of the fixed laws according to which elements combine, and the introduction of the *atomic theory*, produced a total change in the principles of chemical notation. From

this time each element was denoted by a special sign, which at the same time represented a quantity by weight proportional to the weight of a single atom. [ATOMIC THEORY; EQUIVALENT.] In 1815, after accurate determinations of the combining numbers of the elements, Berzelius proposed a system of notation which, with some modifications, has become completely identified with the pursuit of chemistry. This system in its more modern form we now proceed to describe.

Each element is designated by the capital letter of its Latin name, and in the case of the less important elements the most characteristic letter of the word is added as a further distinction. These symbols are moreover made to represent not only the element itself, but also that proportion by weight in which it invariably enters into combination. For a list of these symbols and combining numbers, see **CHEMICAL NOMENCLATURE**. Mere addition of one substance to another is denoted by the sign +; but combination is expressed by the juxtaposition of the symbols. Thus water upon this plan is H_2O , or is composed of one part by weight of hydrogen to eight parts of oxygen. When an element enters into combination in a quantity that is a multiple of its combining proportion, this is expressed by writing the corresponding number on the right a little below the symbol, or else prefixing it in the manner of a coefficient: thus, teroxide of phosphorus, PI_3 . Combination between compound bodies is expressed in a similar manner, or a comma is sometimes interposed. A number standing before a continuous group of symbols signifies the multiplication of the whole group by that number. Sometimes a group is enclosed in a bracket with the same object. The following are examples:—

Sulphate of iron, FeO, SO_4 , or $FeSO_4$.
Tribasic phosphate of lime, $3CaO, PO_4$, or $Ca_3P_4O_{10}$.
Basic carbonate of zinc, $3(ZnO, CO_2)$, $3(ZnO, HO)$.

The changes which take place in chemical reactions are usually represented by equations. The substances existing before the reaction are placed on the left of the sign =, and those resulting from it on the right. Thus the action of common salt on a solution of nitrate of silver with the production of chloride of silver and nitrate of soda is expressed by

This equation affirms moreover that from 170 parts of nitrate of silver and $58\frac{1}{2}$ parts of salt, we obtain $143\frac{1}{2}$ of chloride of silver and 85 of nitrate of soda.

Within the last few years certain new views entertained by chemists respecting chemical combination and the construction of compound bodies, have led to some important alterations in the atomic weights represented by the symbols, whereby the formulae for most substances have become altered. These alterations constitute the chief features of what is called

NOTATION

the new notation. In order that the symbols may more perfectly represent the true combining proportions of the elements which they denote, the new notation requires that the atomic weights of oxygen, sulphur, selenium, carbon, silicon and most metals should be doubled. The reasons for these alterations can be best illustrated by shortly stating the chief of those concerned with the doubling of the atomic weight of the most important, viz. oxygen. 1. Physical considerations render it highly probable that equal bulks of elementary gases and vapours contain an equal number of atoms. 2. When hydrogen and oxygen unite to form water, two volumes of the former combine with one volume of the latter. 3. The hydrogen in water can be replaced in two separate portions by other elements, such as potassium, sodium, and chlorine. 4. When water is generated by decomposition from other substances, the quantity is always such that it contains either two atoms or a multiple of two atoms of hydrogen. The foregoing considerations indicate that the smallest quantity of water ever engaged in a chemical reaction is composed of two atoms of hydrogen united with one atom of oxygen, and the atomic weight of the latter must therefore be 16. Again, when oxygen forms a series of combinations with a compound body, each additional quantity of oxygen combining with the latter is always sixteen parts or some multiple of sixteen parts. Furthermore, the specific gravities in the gaseous condition of nearly all elements capable of assuming that condition are proportional to their atomic weights. But if the specific gravity of hydrogen be called 1, then the specific gravity of oxygen is found to be 16. The foregoing reasons, therefore, lead to the adoption of the atomic weight 16 for oxygen. Consequently, water must be represented by H_2O instead of HO . The doubling of the atomic weights of other elements either follows from direct analogy, or is supported by similar facts. The doubled atomic weights are often distinguished by a mark through the symbol, as above.

The application of this notation to the expression of chemical composition, though sometimes involving more complex formulæ, indicates far more clearly the mutual relations of bodies and the decompositions of which they are susceptible. The new formulæ express, with very few exceptions, the elementary composition by gaseous volume as well as by weight: thus $HClO$ indicates that hypochlorous acid contains equal volumes of its elements. The formulæ also express, with very few exceptions, the weights of the substances denoted by them, which in the gaseous state occupy equal volumes. A great advantage derived from the employment of the new notation, and which deserves special notice, is the prominent expression it gives to the idea of atomicity. This conception, though clearly recognised in the old notation, required the new to develop it completely. Atomicity may roughly be defined as the capacity possessed by any atom of attaching other atoms to itself.

Those elements which combine with one atom of hydrogen, or can replace the latter, atom for atom, in compounds, are called *monatomic*. Those elements whose atoms can attach to themselves two atoms of a monatomic element are called *diatomic*. Thus oxygen requires two atoms of hydrogen to form water H_2O , or one atom of diatomic calcium to form lime CaO . Similarly carbon is tetratomic in marsh gas CH_4 , and carbonic anhydride CO_2 , while nitrogen is triatomic in ammonia NH_3 , and pentatomic in ammoniac NH_4Cl . This atomic character of an element is termed its *atomicity*, and is frequently marked by dashes, or Roman numerals, after the symbols. The following is a classification of the elements with their new atomic weights, founded on the atomic ties which they manifest in their principal combinations. This atomic character is, however, by no means invariable, since the *atomicity* of an element may vary in its different compounds; but in reference to such variation, it has been remarked, that although a monatomic element may become triatomic or pentatomic, it can never be diatomic, tetratomic, or hexatomic, whilst a diatomic element may become tetratomic, but never monatomic or triatomic. In other words, an odd-atomic element can never become even-atomic, and vice versa.

Monatomic.

H 1	I 127	Rb 85.5

The theory of types forms a valuable addition to chemical notation, and owes its development mainly to the new system. According to this theory, a large number of bodies of complex character are considered to be formed on the plan or model of certain compounds of simple character, from which they are assumed to be derived by substitution. The principal types used by chemists are the hydrogen, water, ammonia, carbonic anhydride,

NOTATION

chloride of ammonium, and chloride of sulphuryl types.

Hydrogen Type.

Hydrogen	Chloride of Ethyl	Acetone
H	$\left. \begin{matrix} C_2H_5 \\ Cl \end{matrix} \right\}$	$\left. \begin{matrix} C_3H_5O \\ CH_3 \end{matrix} \right\}$

Water Type.

Water	Alcohol	Acetate of Sodium
$\left. \begin{matrix} H \\ H \end{matrix} \right\} O''$	$\left. \begin{matrix} C_2H_5 \\ H \end{matrix} \right\} O''$	$\left. \begin{matrix} C_2H_5O \\ H \end{matrix} \right\} O''$

Ammonia Type.

Ammonia	Potassamide	Trimethylphosphine
$N''' \left\{ \begin{matrix} H \\ H \\ H \end{matrix} \right.$	$N''' \left\{ \begin{matrix} K \\ H \\ H \end{matrix} \right.$	$P''' \left\{ \begin{matrix} CH_3 \\ CH_3 \\ CH_3 \end{matrix} \right.$

Carbonic Anhydride Type.

Carbonic Anhydride Phosgene Gas Methylal Alcohol

$\left. \begin{matrix} O'' \\ O'' \end{matrix} \right\}$	$\left. \begin{matrix} O'' \\ Cl \\ Cl \end{matrix} \right\}$	$\left. \begin{matrix} H \\ H \\ H \\ OH \end{matrix} \right\}$
--	---	---

Chloride of Ammonium Type.

Chloride of Ammonium	Nitric Acid	Hydrochlorate of Aniline
$N' \left\{ \begin{matrix} H \\ H \\ H \\ Cl \end{matrix} \right.$	$N' \left\{ \begin{matrix} O'' \\ O'' \\ OH \end{matrix} \right.$	$N' \left\{ \begin{matrix} C_6H_5 \\ H \\ H \\ H \\ Cl \end{matrix} \right.$

Chloride of Sulphuryl Type.

Chloride of Sulphuryl	Sulphuric Acid	Chromate of Potassium
$S^{vi} \left\{ \begin{matrix} O'' \\ O'' \\ Cl \\ Cl \end{matrix} \right.$	$S^{vi} \left\{ \begin{matrix} O'' \\ O'' \\ OH \\ OH \end{matrix} \right.$	$Cr^{vi} \left\{ \begin{matrix} O'' \\ O'' \\ OK \\ OK \end{matrix} \right.$

The following are examples of chemical compounds formulated according to both methods of notation :—

	Old	New
Nitric acid . . .	$HO.NO_2$	$HN O_2$
Cyanic acid . . .	$HO.C_2NO$	$HCN O$
Perchlorate of potassium . . .	$KO.ClO_4$	$KClO_4$
Oxalate of lead . . .	$(PbO)_2.C_2O_4$	PbC_2O_4

Notation. Mathematical. Mathematical notation embraces symbols of *number*, *quantity*, and *operation*. Although the origin of our present system of numerical notation is unknown, there is no doubt that it was in use amongst the Hindus two thousand years ago. Its distinctive feature, i.e. symbols having local as well as intrinsic values [ARITHMETIC], implies a state of high civilisation at the period of its invention. The first numerical symbols consisted probably of strokes or notches cut in wood or stone, and intelligible alike to all nations. Such characters, in fact, are preserved with little alteration in the

NOTCHBOARD

Roman notation, an account of which may be found in *Leslie's Philosophy of Arithmetic*.

The numeral notation of the Greeks, though far less convenient than that now in use, was formed on a perfectly regular and scientific plan, and could be used with tolerable effect as an instrument of calculation, to which purpose the Roman system was totally inapplicable. The Greeks divided the twenty-four letters of their alphabet into three classes, and, by adding another symbol to each class, they had characters to represent the units, tens, and hundreds. (Delambre's *Astronomie Ancienne*, t. ii.)

Letters of the alphabet are now used as symbols of quantity; and although much diversity exists with respect to the choice of letters, there are several universally recognised rules. Thus in the theory of equations the first letters of the alphabet denote known coefficients, the last letters the unknown terms. In algebraic geometry, again, a similar rule is observed, the last letters of the alphabet there denoting the *variable* or *current* coordinates. Certain letters, such as π , e , &c., are by universal consent appropriated as symbols of the frequently occurring numbers 3.14159 . . . and 2.7182818 . . . &c., and their use in any other acceptance is avoided as much as possible.

Letters, too, are employed as symbols of operation, and with them other arbitrary characters, such as $+$, $-$, \times , \div , $\sqrt{}$, &c. . .

The letters d, \int are appropriated as operative symbols in the differential and integral calculus, Δ and Σ in the calculus of differences, and so on.

In *functional notation*, a letter, as a symbol of operation, is usually combined with another which is regarded as a symbol of quantity. Thus $F(x)$ denotes the *result* of the performance of the operation F upon the *subject* x . If upon this result the same operation were repeated, the new result would be expressed by $F[F(x)]$, or more concisely by $F^2(x)$, and so on. The quantity x itself may be regarded as the result of the same operation F upon some other function; the proper symbol for which is, by analogy, $F^{-1}(x)$. Thus F and F^{-1} are symbols of *inverse operations*, the former cancelling the effect of the latter on the subject x . $F(x)$ and $F^{-1}(x)$ in a similar manner are termed *inverse functions*.

The history of mathematics shows that improvements in notation have not only been the result of deeper mathematical insight, but the means by which most important discoveries have been made; in short, that a well-chosen system of notation is of the highest importance to science. Our recent progress in algebra and algebraic geometry is due, to a great extent, to the increased power acquired by the cultivation of more symmetrical and concise methods of notation. The notation of determinants and that of quantics, although of quite modern origin, has already done good service.

Notchboard. In Architecture, the board that receives the ends of the steps in a staircase is so called, because it is notched out to

receive the ends of the steps; the wall string is sometimes the notched board.

Note (Lat. note, a mark). In Music, a character by which musical sounds are marked, as well as the swiftness or slowness of their motions.

Notes (Lat. note). In Literature, originally marks affixed, by the critics who reviewed the works of an author, to those places which they considered to be spurious or faulty, or which on any other account were worthy of remark. In modern times the meaning of the term has been enlarged, being now used as synonymous with *annotation* or *commentary*. Among the Romans, praiseworthy passages were usually marked with LL. (i.e. laudabiles loci); and faulty passages indicated by θ (Per. Sat. iv. 12), borrowed from the practice of the judges, who set their mark against those whom they adjudged worthy of death (θδvatos). Good passages were also marked χ, for χρηστός, excellent.

Notes. In Printing, notes are of three kinds: (1) shoulder notes—these are at the top of the page in the outer margin, and contain the book, chapter, or date; (2) side notes or marginal notes, which give an abstract of the text, as in Acts of Parliament, or parallel passages, and different readings, as in the Bible; and (3) bottom notes, or foot notes, which are placed at the bottom of the page, and generally contain commentaries and explanatory annotations.

Notelma. (Gr. νότος, the south, and ἐλαία, the olive). An Australasian genus of *Oleaceæ*, one species of which, *N. ligustrina*, is the Tasmanian Ironwood, so called from the hardness and density of its wood, which does not, however, attain large size.

Nothing. In Mathematical language, the term *nothing* is of frequent occurrence, and denotes either the absence of magnitude in circumstances in which magnitude might have existed, or it denotes the limit to which a variable magnitude approaches by continual diminution.

Nothing, Differences of. [DIFFERENCES OF ZERO.]

Nothosaurus (νόθος, illegitimate, and σαῦρος, lizard). A genus of Saurapterygian reptiles from the Triassic (muschelkalk) deposits of Germany. It offered much analogy to the genera *Sinosaurus* and *Plesiosaurus*. The *Nothosaurus mirabilis*, from Bayreuth, gives the earliest indication of the modification of the trunk bones, which reaches its maximum in the more specialised *Saurapterygia*, *Plesiosaurus*, and *Miosaurus*.

Notice. In Law, that notice by which a party is supposed to communicate, or to receive, the presumed or real knowledge which is necessary to affect the receiver with legal liabilities. For instance, when a party purchases or takes a transfer of a debt, he must give notice to the debtor that he has done so, and until such notice is given his title is not complete, for the debtor, if he has no notice of the trans-

action, may pay his debt to the original creditor, and will be discharged by his receipt. Again, if a creditor assigns his debt to A and B successively, and B gives notice of his own assignment to the debtor before A gives notice of his, B shall have priority over A. And the same rule applies to the title to funds vested in trustees and other similar species of property. Constructive notice is that which is presumed to arise from certain facts: as, for instance, in equity, if a purchaser buy land from A in which he knows that B is interested, as mortgagee, tenant, or otherwise, he will be deemed to have constructive notice of the actual extent of B's interest although he may have been misinformed on that point by A, for it is his duty to seek information on the subject from B himself, and in matters of this kind notice to the solicitor or agent is equivalent to notice to the principal.

Notices which pass between landlord and tenant are familiar in practice. Of these the most important is *notice to quit*, which must be given by either party, in the ordinary case of a tenancy from year to year, six months before the termination of the current year of the tenancy; this may of course be varied by written agreement, and is said to be so in some cases by local custom. The reservation of the rent quarterly does not dispense with the necessity for a half-year's notice. If the landlord receives or distrains for rent after serving a notice to quit, it is a waiver of that notice.

Notite. A variety of Palagonite from Val di Noto, in Sicily.

Notodonta (Gr. νῶτος, back; ὀδούς, tooth). The name of a genus of Lepidopterous insects.

Notoneotidae. [HYDROCORINÆ.]

Nototherium (Gr. νότος, the south, and θηρίον, beast). A gigantic kangaroo-like animal, which flourished during the pliocene period in Australia. It was undoubtedly herbivorous, and offered many points of analogy to the existing koala (*Phascolarctos*).

Notturmo (Ital.). In Music, a term originally synonymous with SERENADE [which see]; but applied at present to a piece of music in which the emotions, chiefly of love and tenderness, are developed. The notturno is a favourite movement with modern pianoforte composers.

Noun (Lat. nomen, a name). In Grammar, that part of speech which denotes a *conception*; in contradistinction to an affirmation or judgment, which is expressed by a *verb*. Nouns are divided into substantives and adjectives; the first denoting real or supposed *substances*, the second qualities or properties conceived as belonging to substances. [GRAMMAR.]

Novaculite (Lat. novacula, a razor). A stone of which hones are made for sharpening razors. It is of a slaty structure, and owes its quality of giving an edge to the metal to the fine silicious particles which it contains.

Novatians. The followers of Novatianus, a presbyter of Rome, who founded a sect in the third century, which continued to flourish to the end of the fifth. Novatian denied re-

NOVEL

admission into the church to all who, in time of persecution, or on other accounts, had once lapsed from the faith. In this extreme severity he was opposed by the greater number of the clergy of Rome, and especially by Cornelius, upon whose election to the see Novatian, who was a disappointed candidate, withdrew from his communion, and established a society of which he became himself the first bishop. This sect was also known by the title of Cathari, or Puritans, which they assumed to express their high sense of the excellence necessary to Christians.

Novel (Ital. *novella*, from Lat. *novus*, *new*). A species of prose fictitious composition.

The Italian novella, of which the best and earliest specimens are contained in the *Decamerone* of Boccaccio, was rather a short tale, turning on an event, or on a series of adventures, of humour, pathos, or intrigue, than a novel in the modern acceptation of the term. In its present signification in the English language it seems to express a species of fictitious narrative somewhat different from a romance; yet it would be difficult to assign the exact distinction, and, in the French language, the same name (*roman*) is used for both; while it differs from a tale merely in the circumstance that a certain degree of length is necessary to constitute a novel.

Although, in fact, the terms *novel* and *romance* are often used indifferently, yet they have often been treated as distinct classes of composition in English literature. It may perhaps be said, that the proper object of a novel is the delineation of social manners, or the development of a story founded on the incidents of ordinary life, or both together. On this hypothesis, we must exclude from the class of novels, on the one hand, tales of which the incidents are not merely improbable (for this may be the case in a novel), but occurring out of the common course of life, and such as are founded on imaginary times and imaginary manners, tales of supernatural incidents, chivalrous romances, &c.; and, on the other hand, fictitious narratives, in which the author's principal object is neither the story nor the costume, but which are obviously written with an ulterior view. Thus, political, philosophical, and satirical fictions are clearly not to be ranked as novels. But it is obvious that no definition can be drawn which shall, on this subject, entirely satisfy the caprices of popular language.

Of the novel, in this confined sense, the works of Richardson, and those of Fielding and Smollett, afforded, perhaps, the first examples in English literature. The first of these authors gave birth to the sentimental novel, the latter two to the comic or humorous. Marivaux, Prévost, &c. spread the former style of composition in France; where, as well as on the Continent generally, it attained a high degree of popularity. The novel of manners, whether comic or serious, has generally been a more popular species of fiction in England,

NUCLEUS

and has attained, perhaps, its highest amount of popularity in the writings of Dickens and Thackeray.

Novels (Lat. *novellæ constitutiones*, *new constitutions*). In the Roman Law, supplementary constitutions of some emperors, so called because they appeared after the authentic publications of law made by them. Those of Justinian are the best known, and are commonly understood when the general term is used. The *Novels*, together with the *Code* and *Digest*, form the whole body of law which passes under the name of that emperor.

November (Lat. from *novem*, *nine*). The eleventh month of the Julian year; but the ninth month in the old Roman year, which began with March. [CALENDAR; YEAR.]

November Shower. [METEORA, LUMINOUS.]

Novensiles (Lat.). Certain Latin gods, who are also called Novensides. The first part of the word has been thought by some to be *novem*, *nine*; by others, *novus*, *new*. Hence the word has been taken as a name for the nine Muses, or, with more reason, for gods newly introduced (as after the conquest of a place), in contrast with the *dii indigetes*, or old gods of the country.

Novi Homines (Lat. *new men*). Among the Romans, such persons as, by their own personal merit, had raised themselves to curule dignities without the aid of family connections. [NOBILITY; NOBLE.]

Novice (Lat. *novitius*, *new*). A person admitted into a religious community as an inmate for the purpose of preparation for becoming a member. The state of preparation is termed *novitiate*. The custom of giving novices the religious dress did not begin until the twelfth century. The age of profession is fixed by the council of Trent at sixteen years. During the period of the novitiate the novice is still at liberty to relinquish his intention.

Nox (Lat.; Gr. *νύξ*). In Mythology, the goddess of night, daughter of Chaos, sister of Erebus, darkness, the mother of *Æther*, air, and *Hemera*, the day.

Noyades (Fr. *noyer*). The name given to a peculiar punishment resorted to in the first French revolution. The *noyades* were effected by drawing out a plug inserted in the bottom of a boat in which the wretched victims were launched. The genius of iniquity, says a writer in the *Edinburgh Review*, often displays itself in the same invention. When Nero wished to kill his mother, Anicetus proposed to him to place her in a ship so framed as to open in part and deposit her in the sea. (Tac. *Ann.* lib. xiv. 8.)

Noyau (Fr.). A liqueur flavoured by bitter almonds, or the kernels of peach stones.

Nucleus (Lat. dim. of *nux*, a nut). In Astronomy, the solid part or body of a comet, as distinguished from its nebulosity. [COMET.]

Nucleus. In Botany, the central fleshy pulpy mass of an ovule; or that part of a seed which is contained within the testa, and con-

NUCULE

sists of either the embryo and albumen, or of the embryo only. In lichens, this word is applied to the disc of the shield, which contains the sporules and their cases. In the language of the older botanists, that which is now termed by gardeners a *clove*, i.e. the secondary bulb of a bulbous plant, was called a *nucleus*.

Nucule (Lat. *nux, a nus*). In Botany, either that fruit which is otherwise called a gland or acorn, or any small, hard, one-seeded pericarp. The female organ in *Chara* is also called a *nucule*.

Nuc. *sees.* A suborder of the *Cruciferae* in which the silicles are one-celled from the absence of a replum, and often contain but a single seed. *Isatis* furnishes an illustration.

Nude or Naked Contract. In Law, a contract without any consideration for it, on which no action lies (*ex nudo pacto non oritur actio*).

Nudibranchians (Lat. *nudus, naked*; *branchia, gills*). The name of an order of hermaphrodite Gastropodous Molluscs which have the branchiae exposed on some part of the back.

Nudipedalia (Lat. *nudipedalis, barefooted*). A religious ceremony among the Greeks, Romans, and other nations, observed on account of some public calamity, as famine, drought, pestilence, when women appeared with the feet uncovered.

Nudities. In the Fine Arts, figures either wholly or in part divested of drapery.

Nuggets. The name given in California and Australia to the larger lumps of gold occasionally found in the gold alluvium of those countries and elsewhere. Smaller lumps are called *pepitas*, and the finest particles *granos* or gold grains. Nuggets have been found of extraordinary dimensions and weight; but, as may be supposed, they are comparatively rare. They are always water-worn.

Nuisances (from Lat. *nocere, to hurt*). In Law, nuisances are of two kinds: public or common, which annoy the king's subjects in general; and private, which are defined 'anything done to the hurt or annoyance of the lands, tenements, or hereditaments of another.' The general remedy for public nuisances is by indictment or presentment; for private nuisances, by action for damages. In either case, the Court of Chancery will grant an injunction against the continuance of the nuisance; and this remedy is now commonly resorted to.

Nullah. The name given by the Hindus to small rivers or streams.

Nullipores (Lat. *nullus, none*; *porus, a pore*). The name of a family of Lithophytous Polypes, the axis of which presents no visible pores on its surface.

Nullity of Marriage, Suit for. In Law, this suit is instituted for the purpose of obtaining a sentence in the Court of Matrimonial Causes declaring a marriage void which, without such sentence, is voidable

NUMBERS, THEORY OF

only. [*MARRIAGE, LAW OF.*] Also, sometimes where a marriage is actually void from the circumstances under which it was contracted, in order to procure a solemn judicial declaration to that effect.

Number (Lat. *numerus*). Number is defined by Euclid to be an assemblage or collection of units or things of the same species. This definition excludes the unit itself, or 1. Newton defines number as the abstract ratio of one quantity to another quantity of the same species; and hence there are three kinds of numbers, namely, integers, fractions, and surds. Number, abstractedly considered, conveys merely the notion of *times* or *repetitions*.

Mathematicians consider numbers under different points of view, or with relation to different properties; and hence arise the various distinctions which have been introduced, as even or odd, whole or fractional, rational or irrational, perfect or imperfect, prime or composite, abundant or defective, simple or complex, &c. Numbers also acquire various denominations from the manner in which they are composed; as TRIANGULAR NUMBERS, PYRAMIDAL NUMBERS, POLYGONAL NUMBERS, &c.

Number. In Metaphysics. [*SPACE.*]

Numbers of Bernoulli. [*BERNOULLI'S NUMBERS.*]

Numbers, Theory of. By this name it is customary to distinguish that branch of Mathematics which, transcending ordinary arithmetic, is concerned principally with the theory of congruences and the theory of homogeneous forms, both of which theories are closely connected with the solution of indeterminate equations. In a work of the present kind, any exposition, however brief, of more than the mere elements of the theory would be out of place. We shall, therefore, limit ourselves here to a reference to some of the best works on the subject, and reserve, for their appropriate places, brief enunciations of a few of the more salient theorems, and short explanations of the more frequently occurring technical expressions.

The standard works on the Theory of Numbers are the *Disquisitiones Arithmeticae* of Gauss (Lipsia 1801) and the *Théorie des Nombres* of Legendre (Paris 1830). Almost every modern mathematician of eminence, however, has contributed more or less to the advancement of the theory. In the collected works of Euler, Gauss, Jacobi, Cauchy, Dirichlet, Lagrange, Eisenstein, Poinsoot, and others, numerous memoirs on the subject will be found; whilst the recent mathematical journals and academical transactions contain researches in the same wide field, by all the ablest of living mathematicians. Every student of the Theory of Numbers will do well to consult Professor H. J. S. Smith's excellent 'Reports on the Theory of Numbers,' which commenced in the *Transactions of the British Association* for 1859. He will find the concise and lucid critical history of the subject which is there given, rendered doubly valuable by

NUMENIA

copious references to the original sources of information.

Numenia. [NOMENIA.]

Numenius. The name under which Cuvier separated the curlews, as a distinct genus, from the other *Scolopaces* of Linnaeus. They have a beak arcuated like that of the ibis, but it is more slender, and is cylindrical throughout; the tip of the upper mandible extends beyond the end of the lower one, and projects a little downwards in front of it. The toes are palmed at the base.

Numerals. The symbols or characters by which numbers are expressed. [NOTATION.]

Numeration. The primary object of numeration is to find names for the different numbers; and, as there are an infinity of numbers, while the number of words is limited, it became necessary to devise some systematic method of combining a few words, so as to express by means of them any number whatever. It is obvious that when large numbers are to be expressed, the lower scales, as the binary, ternary, &c., would be exceedingly inconvenient on account of the multitude of words that would be required. On the other hand, as a name is required for at least every unit in the scale, a very high scale would be no less inconvenient. In the denary scale, the nomenclature is sufficiently convenient, and in our language almost perfectly regular. A name is given to the 9 units of the first order; the unit of the second order is *ten*; and by the different combinations of this word all numbers are named to 99: eleven and twelve are only *apparent* exceptions. A new appellation is wanted for the unit of the third order, or *hundred*. This suffices till we reach the fourth order, or *thousands*; and might even have sufficed to a hundred *hundreds*, or ten thousand. A thousand thousands is called a million, and a million millions a billion; further continuation is useless.

The second object of numeration is to express the nomenclature thus formed by the combinations of a small number of written symbols. This is most conveniently effected by the very refined artifice of giving to each symbol a *local* as well as an *absolute* value. So that the same symbol, 3 for example, is made to express not only 3 *units*, but 3 *tens*, 3 *hundreds*, 3 *thousands* &c.; or 3 *tenth parts*, 3 *hundredth parts*, &c., according to its distance, to the left or right, from the unit's place in any combination of symbols. [NOTATION.]

Numerator. In Arithmetic, that part of the numerical expression of a fraction which indicates how many of those parts into which the unit is supposed to be divided are expressed. Thus, in the fraction $\frac{7}{12}$, the lower number 12 is the denominator, and shows that the unit is divided into 12 parts; 7 is the *numerator*, and shows how many of those parts are to be taken.

Numerical. A term used in Mathematics in opposition to *algebraical* or *literal*. Thus a numerical equation is one whose coefficients are all *expressed* numbers. [EQUATION.] Again, in

NUMISMATICS

speaking of the *numerical value* of a quantity, as opposed to its *algebraical value*, the prefixed sign is not regarded. Thus the numerical value of -7 is said to exceed that of -8, although the former has a less algebraical value.

Numida (from Numidia, where, however, this bird was not found). The bird *N. meleagris*, termed *pintado* by the Spanish, and *pearl-hen* and *Guinea-hen* by the English, forms the type of this genus. This bird came originally from the western coast of Africa; and since its introduction into England it has been widely diffused. When transported to Jamaica, it reverts to its original wild condition. Two species of the genus are known, the second (*N. cristata*) inhabiting Southern Africa.

Numismatics (from Gr. *numos*, Lat. *nummus*, a coin). The science of coins and medals. The distinction between these classes of objects is, in modern times, that the coin is struck for the purpose of circulation as money; the medal not as a piece of money, but as a token commemorative of some person or event. But ancient coins are often termed, in common language, *medals*. The parts of coin or medal are: the obverse or face, containing generally the head, bust, or figure of the sovereign or person in whose honour the medal was struck, or some emblematic figure in the coins of commonwealths; and the reverse, containing various figures or words. The words around the border of the coin form what is termed the *legend*, those in the middle the *inscription*; when occupying the lower extremity of the pieces, and separated from the rest by a horizontal line, they are termed the *exergue*.

The earliest Grecian coins which we possess appear to have been nearly of a spherical shape. They contain, on the obverse, some emblems of the particular cities which struck them, and on the reverse, deep indentations made by the puncheon in which the metal was held while the obverse was struck. These marks, or the die, were soon brought into a more regular shape, sometimes forming a neat square, sometimes a circle. Types were afterwards introduced on both surfaces of the coin, by inserting some small object in one compartment of the die. Ancient coins have been divided into various historical series, as exhibited in the following table:—

		(Of Græcia Propria and the
	1. Civic	Of Greek colonies. Of Græco-Asiatic cities. (Kings of Macedon.
Grecian	2. Monarchole	Kings of states formed out of the Macedonian conquests: Syria, Egypt, &c. &c.; and the independent princes of Epirus and Syracuse.
	1. Consular	Roman ævæ. Coins of the families.
Roman	2. Imperial	Grecian.—Provinces, Colonies, and Municipia.
	3. Medallions	Grecian. Roman.
Barbarian	1. European: of Thrace, &c.	
	2. Asiatic: of Persia, &c.	
	3. African.	

NUMISMATICS

The objects on Grecian civic coins are either, 1. the emblems of the cities; 2. figures of deities, and their attributes; 3. miscellaneous or general symbols, usurped by many states and cities, usually consisting of warlike objects. The legends on Greek republican coins are either the name of the city or its initial letters; or monograms, i.e. figures forming a portion of the name, in which the characters are so interlaced that a limb of one applies to many.

The earliest coins which bore the heads of princes were those of Macedon, commencing with Alexander the Great, and closing with the extinction of the dynasty of the Lagides in the Augustan age. Four principal series of Grecian monarchical coins (either of Greek states or such as adopted the Greek language and customs) have been formed: 1. Of Macedon; 2. Of Sicily, Caria, Cyprus, Heraclea, Pontus; 3. Of Egypt, Syria, the Cimmerian Bosphorus, Thrace, &c. &c., from the era of Alexander the Great down to that of Christ; 4. Of dynasties which flourished subsequently to the latter era; including some kings of Thrace, Bosphorus, and Parthia, with those of Comagene, Edessa, Judaea; to which may be added some lines of Romanised monarchs, as those of Mauritania. The most beautiful monarchic series are those of the Seleucids in Syria, and of the Ptolemies in Egypt. The unit of the Grecian silver coinage, in point of value, may be considered as the drachma, which is of a size between our sixpence and shilling; the smallest silver coin is the dichalcos, only $\frac{1}{16}$ th of the drachma; the largest, the tetradrachma, containing four drachmas. The commonest gold coin is the didrachma, weighing two silver drachmas, and in value 20s. or 16s. sterling. Grecian copper coins are generally small.

The Roman coinage differs from the Grecian in many respects; the greater size of the copper coins in early times, and their superior workmanship in later, the prevailing simplicity of devices, &c., form characteristic marks of difference. In the first period of the republic they were cast. The consular copper coins have separate symbols for the pieces, according to their respective value; as the head of Janus for the *as*, Jupiter for the *semis*, &c. The *as* also bore the impress 1, to denote its quality of unity as a measure of value. The name *family coins*, applied to many coins of the republic, arose from the custom of inserting the name of some distinguished family in the field of the coins. A silver coinage was first introduced into Rome 226 a.c. The oldest coin was the *denarius*, equivalent to ten *asses*: the earliest of these have the head of Janus, for which that of Rome was afterwards substituted on the obverse, with a variety of symbols on the reverse. The coinage of gold was introduced into Rome sixty years after that of silver: the pieces were—the *scrupulum*, one-third of the *denarius* in weight; a coin weighing two-thirds; and another weighing a whole *denarius*. Afterwards the chief gold coin was the *aureus* (twice the weight of the *denarius*).

NUMMULITIC FORMATION

The imperial Roman coins form by far the most complete and varied series which we possess of ancient or modern times. The symbols on the reverse have been arranged under four heads: as relating to religion; war; games, and the embellishments of the city, under the numerous subdivisions of these subjects. The obverses contain the portraits of emperors and empresses. The characters on the reverses of the coins are, generally speaking, explanatory of the type; expressing in a few brief words the history of some occurrence immediately after which the coin was struck, &c. The legends on the obverse mostly contain titles annexed to the imperial dignity, often expressed in abbreviations productive of not a little obscurity.

Not less than three hundred portraits are preserved in the series of Roman imperial coins. The term *medallion* is applied to those productions of the Roman or provincial mints which, in gold, exceed the size of the aureus; in silver, of the *denarius*; in copper, of the largest copper coin of ascertained value. It is doubtful whether they were intended for circulation as coins, or struck, like medals among ourselves, as commemorative tokens.

Modern coins present so wide a variety as to render it impossible to include any classification of them within the limits of the present notice. In Britain, Roman coins were current until the arrival of the Saxons: we have the coins of five out of the seven kingdoms of the heptarchy; among them some small copper coins, the only specimens of that metal coined before the reign of Elizabeth. Coins struck prior to the reign of Charles II. had their devices impressed by the blows of a hammer. The system of lettering on the edges, which was succeeded by graining, was devised in order to obviate the fraudulent practice of clipping and filing the current coin.

Nummulites. An extinct genus of foraminiferous Acrites, of a thin lenticular shape, divided internally into small chambers. These occur so abundantly in some parts of the chalk formation, that the name of nummulitic limestone is given to the strata so characterised.

Nummulitic Formation. A very remarkable series of limestones, often of great thickness, containing a peculiar fossil, the *Nummulites*, in incredible abundance, belonging to the middle division of the lower tertiary, and ranging more widely than any known tertiary rock. They reach from China by the Himalayan Mountains to the mouths of the Indus, thence by Persia to the Mediterranean, entering largely into the Carpathian and Alpine mountain masses, extending through the South of France to the Pyrenees, and thence across to the south of Spain and the north of Africa. In the Alps the nummulitic beds are called *Flysch* [which see]. As a single group of deposits characterised uniformly by the same fossils, the nummulitic formation is certainly the most widely spread of all the tertiaries; and although not represented in England in precisely the same

NUNCIO

form as elsewhere, the foraminiferous fossils of the London clay are doubtless of the same date.

So widely distributed are these deposits, that they extend over an area measuring no less than twenty-five degrees of latitude and 100 degrees of longitude in extent. In Western Tibet they have been found 16,500 feet above the level of the sea. In China they are met with, and they are known throughout Eastern Bengal.

Nuncio (Ital. from Lat. *nuntius*, a messenger). An envoy of the pope to the court of an emperor or king to negotiate ecclesiastical affairs. [LEGATE.] Before the council of Trent the papal nuncios acted as judges in the first instance of matters which lay within ecclesiastical jurisdiction; but since that time they have formed a kind of court of appeal from the decisions of the respective bishops. This jurisdiction, however, holds good only in those countries which still hold themselves subject to the decretals and discipline of the council of Trent; for in other kingdoms and states, such as France, Austria, &c., which, though Roman Catholic, hold themselves independent of the Roman pontiff in matters of discipline, the papal nuncio has no jurisdiction whatever, and is invested merely with a diplomatic character, like the ambassadors of any secular power. In 1863 the court of Rome had, nominally, twelve nuncios in different countries; but several of those were attached to the small Italian courts, abolished by the union of Italy.

Nuncupative Will (Lat. *nuncupo*, I name). In Law, a will orally delivered by the testator. By English law, however, all wills must, as a general rule, be in writing, and executed with certain prescribed formalities; but an exception prevails in some cases and for some purposes in favour of soldiers on an actual military expedition and of seamen at [WILL.]

(Lat.). The market-days or fairs at Rome were so called, because they recurred every ninth day. On this day the people from the country and the neighbouring towns flocked to Rome with the produce of their farms or industry. On that day, also, all public proclamations were made, causes heard, witnesses cited, and judgments given. The nundine were *feriæ* or *dies nefasti* for the populus or patricians, while for the plebs they were *dies fasti*; but it is said that this distinction was removed by the *Lex Hortensia*.

Nuns (Ital. *nonna*). Female devotees among the Roman Catholics, who, like the monks of the other sex, seclude themselves in religious communities.

Among nuns, as among monks, there are various orders; some devoting themselves entirely to contemplation and spiritual exercises, but many others to the more active duties of private and public charity. [MONACHISM; ORDERS, RELIGIOUS; see also the several orders of nuns under their respective heads.]

NUT

Nuphar (Arab. *noufar*). One of the Water-lilies of our streams and rivers. *N. lutea* is the Yellow Water-lily, whose broad orbicular leaves float on the surface of the water, the yellow blossoms with a perfume of brandy (hence called *brandy-bottle*) rising here and there between them. The seeds contain a good deal of starch, and are sometimes used as food.

Nursery. In Gardening, a plot of ground, or an entire garden, set apart for the propagation of plants, more particularly trees and shrubs. The situation ought to be open and airy, and the soil of an average quality, neither too heavy nor too light, so as to be adapted to the majority of plants. In a complete nursery there ought also to be shady borders for plants requiring shade, and beds or compartments of peat soil, or other peculiar soils, for such plants as are not readily propagated and grown in ordinary soils. Where tender plants are propagated, or where hardy plants are to be raised from seeds or struck from cuttings which are not easily germinated or rooted in the open ground and in the ordinary manner, hot-beds, frames, and hand-glasses are also requisite.

Every private garden of any extent requires a nursery to raise and bring forward young plants as a reserve for supplying failures by disease or accident in the general garden; and in every country where private gardens or plantations of trees are frequent, public or commercial nurseries are formed by persons who adopt nursery gardening as a business.

Nussierite. A phosphate of lead and lime with chloride of lead, occurring in obtuse rhombohedrons of a yellowish, greenish, or greyish colour, with a faint waxy lustre, at Nussière, in the department of the Rhône, in France.

Nut (Lat. *nux*). In Botany, a hard indehiscent pericarp usually containing only one seed. The word *nut* is also applied in popular language to the fruit or kernel of the seed of various plants, some of the more important instances being those of *Moringa pterygosperma*, the Ben-nut; of *Caryocar nuciferum*, the Butter-nut; of *Anacardium occidentale*, the Cashew-nut; of *Castanea vesca*, the Chest-nut; of *Cola acuminata*, the Kola-nut; of *Arachis hypogea*, the Ground-nut; of *Cocos nucifera*, the Cocoa-nut; of *Phytolphas macrocarpa*, the Ivory-nut; of *Semecarpus Anacardium*, the Marking-nut; of *Curcas purgans*, the Physic-nut; of *Strychnos nux vomica*, the Poison-nut; of *Lecythis Zabucajo*, the Sapucaia-nut, and various others.

The name is also commonly applied to the fruit of different species of *Fraxinus* or hazel. The kernels of these have a mild farinaceous oily taste, agreeable to most palates. A kind of chocolate has been prepared from them, and they have sometimes been made into bread. The expressed oil of hazel nuts is little inferior to that of almonds. Besides those raised at home, nuts are imported from different parts of France, Portugal, and Spain, but chiefly from the latter.

NUT OF A SCREW

The Spanish nuts in highest estimation, though sold by the name of Barcelona nuts, are not shipped thence, but from Tarragona, whence the annual average export is estimated at from 25,000 to 30,000 bags, 4 to the ton.

Nut of a Screw. In Architecture, a piece of wood, iron, or other metal pierced cylindrically, wherein is cut a spiral groove, adapted to an external cylindrical spiral cut in relief in a bolt. Its use is to screw two bodies together, a head being placed on one end of the bolt to counteract the action of the nut, and to keep the bodies to be connected in contact. Two bodies are thus held together by compression, the bolt between the head and the nut acting as a tie.

Nutation (Lat. *nutatio*, a nodding). In Astronomy, the name given to a small gyratory movement of the earth's axis, in virtue of which, if it subsisted alone without the precession of the equinoxes, the pole of the equator would describe among the stars, in a period of about nineteen years, a small ellipse, having its longer axis equal to $18\cdot5''$, and its shorter one to $13\cdot74''$; the longer being directed to the pole of the ecliptic.

In order to understand the nature of this phenomenon, it is necessary to consider it in connection with that of precession, as both depend on the same physical cause, and form, in fact, essential constituent parts of one and the same great phenomenon. The action of the sun and moon on the protuberant mass about the earth's equator tends constantly to draw the plane of the equator towards that of the ecliptic, or to diminish the angle between them. In consequence of the earth's rapid rotation about its axis, the inclination of the two planes is not permanently altered, but a motion is communicated to the plane of the equator, of such a kind that its axis revolves with a slow conical motion about the axis of the ecliptic; or, which is the same thing, the pole of the equator describes a circle in the heavens about the pole of the ecliptic as a centre, keeping constantly at the same mean distance of about $23^{\circ} 28'$ from it. The direction of this motion is from east to west, and its velocity amounts only to $50\cdot1''$ annually, so that the whole circle requires for its description a period of 25,868 years.

As the effect of the sun or moon in giving the earth a motion about its centre of gravity varies with the distance of the attracting body from the plane of the equator, it is evident that the effect of the sun is greatest at the solstices, and is reduced to nothing at the equinoxes. On this account, the obliquity of the ecliptic is subject to a small semi-annual variation, depending on the sun alone. This is called the *solar nutation*. Its existence is, however, only a deduction from the theory of attraction; for its amount, which is less than half a second, is too small to be sensible to observation. The result produced by the combined action of the sun and moon is called the *luni-solar nutation*; though the sensible part of it is produced only

NUTMEG

by the moon, and follows exactly the period of the moon's nodes.

The uranographical effect of the nutation is to produce a periodical fluctuation of the apparent obliquity of the ecliptic, and of the velocity of the retrogression of the equinoctial points. In fact, the circle which the pole of the equator would describe by virtue of precession is by nutation changed into a wavy line. Hence arises the distinction between apparent and mean right ascension and declination; the former being given by direct observation, and the latter being the results obtained when the observed places of objects have been cleared of the periodical fluctuations arising from nutation. Formulae and tables, for the reduction of observations to a common epoch, are given in all works on practical astronomy. The discovery of the nutation of the terrestrial axis belongs to Bradley, and was a consequence of his other great discovery, the aberration of light.

Nutcracker. A rare British bird of the order *Picæ*, belonging to the genus *Nucifraga*, and termed *caryocatactes* (Gr. *καρυοκατάκτερος*), from its habit of cracking the shells of nuts to obtain the kernel. It is of the size of a jackdaw, but with longer tail. It is not to be confounded with the nuthatch.

Nuthatch. The name of a shy and solitary bird of the genus *Sitta* (*S. europæa*). It frequents woods, and feeds chiefly on insects; but it also eats the kernel of the hazel nut, which it cracks by fixing it in a chink, and striking it from above with all its force. The nuthatch lays her eggs in holes of trees, and hisses like a snake when disturbed.

Nutmeg. The fruit of the *Myristica moschata* (*officinalis*), a beautiful tree of the *Myristicaceæ*, which grows in the Molucca islands. All the parts of this tree are very aromatic; but only those portions of the fruit called *mace* and *nutmeg* are sent into the market. The entire fruit is a species of *drupe*, of an ovoid form, of the size of a peach, and furrowed longitudinally. The nutmeg is the innermost kernel or seed, contained in a thin shell which is surrounded by the mace; and this again is enclosed in a tough fleshy skin, which opening at the tip separates into two valves. The nutmeg tree yields three crops annually: one in April, which is the best; one in August, and one in December.

Good nutmegs should be dense, and feel heavy in the hand. When they have been perforated by worms, they feel light; and though the holes have been fraudulently stopped, the unsound ones may be easily detected by this criterion.

Nutmegs afford two oily products. 1. Butter of nutmeg, vulgarly called oil of mace, is obtained in the Moluccas, by expression, from the fresh nutmegs, to the amount of 50 per cent. of their weight. It is a reddish-yellow butter-like substance, interspersed with light and dark streaks, and possesses the agreeable smell and taste of the nutmeg from the presence of a

NUTRIA

volatile oil. It consists of two fats; one reddish and soft, soluble in cold alcohol; another white and solid, soluble in hot alcohol. 2. The volatile oil known as *oil of mace*, deposits a stearoptene which has been called *myristicin*.

Nutria (Span.). This name for the *Myopotamus Bonariensis* (Commerçon), the *Coyú* of Molina, and the *Quoiya* of D'Azara, is derived most probably from some supposed similarity of the coyú, in appearance and habits, to the otter, the Spanish name for which is *nutria*.

Like the beaver, the coyú is furnished with two kinds of fur; viz. the long ruddy hair, which gives the tone of colour, and the brownish ash-coloured fur at its base, which, like the down of the beaver, is of much importance in hat-making, and the cause of the animal's commercial value.

The habits of the coyú are much like those of most of the other aquatic Rodent animals. Its principal food, in a state of nature, is vegetable. It affects the neighbourhood of water, swims perfectly well, and burrows in the ground. The female brings forth from five to seven at a time; and the young always accompany her. The coyú is easily domesticated, and its manners in captivity are very mild. (Martin, *Proceedings of the Zoological Society*, 1835.)

Nutria fur, largely used in the hat manufacture, has become, within the last fifteen or twenty years, an article of very considerable commercial importance. The imports fluctuate considerably, as many as 600,000 skins having been sometimes imported annually from Buenos Ayres and Chili; but the wars between these states have reduced the exports to about 3,000 skins.

Nutrition. The ultimate and proximate components of the food of animals, and the processes by which it is elaborated in the vegetable world, are subjects which have been elsewhere adverted to [Digestion; Food]: it only remains to notice a few of the leading points bearing upon the physiology of animal nutrition. It is the business of the vegetable creation to absorb certain substances from the soil and from the atmosphere, and to convert them into parts of themselves. These substances are the media by which *inorganic compounds*, as they are usually termed, are changed into *organic products*; and it is through their functions, and in their structures, that the water, carbonic acid, and ammonia, of the atmosphere, together with various substances derived from the soil, are converted into the innumerable products of the vegetable world. Of these products, such only as are essential parts of the food of animals need be mentioned here; gum, starch, sugar, and fat, for instance, on the one hand, and on the other several albuminoids or azotised substances. But besides these, there are required, for the building up of the frame of the herbivorous or grazing animals, many other substances, which pass from the soil into the plant, and through the plant into the animal;

NUTRITION

such as various earthy and saline products (compounds containing metals and metalloids) essential to animal growth: so that if we look at the composition of the food of animals, in reference to its *ultimate elements*, we find that the carbon, hydrogen, oxygen, and nitrogen, the sulphur, phosphorus, and chlorine, the lime, soda, potash, &c., which in the form of water, carbonic acid, ammonia, and certain chlorides, phosphates, and sulphates, are taken from the air and from the soil, are elaborated, by processes infinitely beyond our comprehension, into the *proximate components* of the vegetable; and that among these proximate components, thus elaborated, all the essential materials necessary to the growth and sustenance of animals are to be found. The functions of plants, therefore, include the *formation* of a variety of complicated products out of the comparatively simple materials derived from the air which surrounds them, and from the soil in which they are planted. [BOTANY.] The functions of animals, on the other hand, tend to diametrically opposite effects. Their food is, either directly or indirectly, of vegetable origin, consisting exclusively, as far as graminivorous tribes are concerned, of the complex produce of plants; and their functions tend to the progressive and ultimate resolution of these products into water, carbonic acid, and ammonia, and the other comparatively simple or binary arrangements which we set out with as the food of plants; and a plant can no more live upon the complex combinations which are required for the support of animal life, than an animal can live upon the simple binary combinations essential to vegetable life. These wonderful transmutations of inorganic into organic products through the instrumentality of vegetables, and of organic into inorganic products through the instrumentality of animals, must always be borne in mind, in reference to all the phenomena connected with the nutrition of vegetables and animals, and with all that belongs to the influence of soil and climate, and of food and diet, and as lying at the foundation of all agricultural and sanitary improvements.

Chemical physiologists have taught us that the food of animals may be regarded as including two distinct series of proximate principles; namely, those which do not contain nitrogen, and consist of carbon, hydrogen, and oxygen, and which appear to be chiefly concerned in maintaining animal heat, by a species of slow combustion terminating in the production of carbonic acid and water, which are thrown off by the lungs, and are therefore termed *aliments of respiration*; and those which do contain nitrogen, and which, consisting of carbon, hydrogen, oxygen, and nitrogen, with sulphur and phosphorus, are employed in the formation of the principal organs of the body, and which have therefore been called *plastic elements of nutrition*. The former include starch, gum, sugar, and fat; the latter are the nitrogeniferous products of vegetation (such as gluten, legumine, and albumen), and their

NUTRITION

congeners, the flesh and blood of animals. With both of these, but more especially with the latter, are associated what have been called the inorganic elements of food, namely the saline and earthy matters. The importance of these distinctions will be more evident when they are considered in reference to the animal functions, which, although essentially the same in the carnivorous and graminivorous tribes, may be most conveniently described in reference to the less complicated machinery of the former; for we are here, of course, obliged to limit ourselves to the higher orders of animals, to the exclusion of the infinite variety of phases which the process of nutrition assumes in the infinitely varied grades of the animal world.

In respect to ourselves, the first operation which the food undergoes is that of mastication, and mixture with saliva; it is then propelled through the œsophagus into the stomach, where *digestion*, as it is called, may be said properly to commence. The food is here gradually brought into the state of a comparatively uniform pulpy mass called *chyme*, and becomes mixed with the gastric juice, which acts upon and modifies the nitrogeniferous or azotised aliments (plastic aliments), but does not materially affect the non-azotised or amylaceous, saccharine, and oleaginous food (respiratory aliments). The gastric juice, in consequence of the peculiar action of the pepsine, and of the acid which it contains, softens and ultimately dissolves the albuminous and fleshy parts of the food. The modified contents of the stomach are then propelled into the small intestines, where they meet with the pancreatic juice, the action of which is principally upon the oleaginous and amylaceous ingredients of the food; it forms a perfect and uniform emulsion with the former, and converts the latter into sugar. In the duodenum, the chyme also becomes mixed with the bile which is secreted by the liver, and which, after having remained some time in the gall-bladder, enters the duodenum by the choledic duct. [CHOLEDOCICUS.] What the exact action of the bile is has not been satisfactorily ascertained, but it is necessary to the formation of perfect chyme, and probably plays some important part in the separation of the excrementitious from the absorbable and nutritive part of the food. The chyme, thus perfected by the joint action of the gastric, pancreatic, and hepatic secretions, is now separated into *chyle* (which is absorbed by the lacteals, and ultimately conveyed into the venous blood, to which it restores the various principles which it had lost in the course of its circulation), and into an *unabsorbed residue*, which, together with such other matters as may have resisted the action of the digestive process, is transferred to the large intestines, and ultimately voided in the form of excrement.

The respective attributes of the vegetable and animal creations which have been above adverted to, have been contrasted as follows by Dumas and Cahours:—

NYMPS

VEGETABLES

Produce	Azotised substances.	Consume	Azotised substances.
	Fatty matters.		Fatty matters.
	Starch, gum, sugar.		Starch, gum, sugar.
Decompose	Carbonic acid.	Produce	Carbonic acid.
	Water.		Water.
	Ammonia.		Ammonia.
Evolves	Oxygen.	Absorb	Oxygen.
Constitute an apparatus of reduction: are stationary.		Constitute an apparatus of oxidisement: are locomotive.	

Nuttallite. A variety of Scapolite, named after Mr. Nuttall, by whom specimens of the mineral were first brought to this country. It occurs in white rectangular prisms, which are yellowish in some parts and in others bluish or green, at Bolton and Boxborough in Massachusetts, in coarse granular limestone, with Epidote and Titanium ore; also in Lewis county, New York.

Nux (Lat. *a nut*). A kind of fruit, hard, dry, not splitting, and containing only one seed. The term is also extended by some writers to any similar fruit, whether it contains one cell or more than one. [NUT.]

Nux Vomica (Lat.). The fruit of *Strychnos nux vomica*, a shrub growing in the East Indies. It contains the alkaloids strychnia and brucia, and is a virulent poison. [STRYCHNOS; STRYCHNIA.]

Nyctaginaceæ (Nyctago, an old synonym of one of the genera). An order of Monochlamyds belonging to the Chenopodal alliance, containing a small number of plants natives of warm countries, few of them of any importance or beauty save *Mirabilis*, the well-known Marvel of Peru, a very showy plant, the flowers being very fragrant in the evening, and a general favourite in the mixed flower garden.

Nyctalops (Gr. *νυκταλωψ*). One who sees distinctly only in twilight, or the dusk of evening. [HEMERALOPIA; NIGHT BLINDNESS.]

Nyishau. The name for one of the largest species of antelopes (*Portax Tragocamelus*), which attains the height of four feet at the shoulder. It has been frequently introduced into our menageries. The horns are about seven inches long, small, round, and black; the pastern joints are marked in front with one white spot, and in the rear with two conspicuous ones of the same colour, which contrast strongly with the dark brown of the surrounding parts and the slaty blue of the rest of the body. It has often bred in confinement, where its vicious and uncertain temper renders it very intractable.

Nymph (Gr. *νύμφη*, *a nymph*). The Metabolian insects are so called when in the second stage of their metamorphosis, especially when they possess the power of locomotion. [PYRA.]

Nymphs (Gr. *νύμφαι*). In Greek Mythology, female beings who peopled all the regions of earth and water. They may be divided into two classes, the one representing powers of nature, the other personifying

NYMPHAOEA

tribes, races, cities, &c. Among the former, the Naiads inhabited the streams, the Oreads the mountains, the Dryads the woods, the Hamadryads trees, with which they were born and died. The Oceanides were nymphs of the ocean; the Potamæides inhabited the rivers; the Napææ dwelt in forests, &c. Their number was almost infinite, and they were represented generally in the form of beautiful maidens.

Nymphææ. In Zoology, a name given by Lamarck to a family of Bivalves.

Nymphaea. The Water-lily genus, represented in our native Flora by *N. alba*, one of the most lovely of aquatic plants, known by its almost circular floating leaves, and white rosette-shaped flowers rising amongst them just above the water. In this genus the ovary is embedded in the receptacle, and internally divided into numerous many-seeded compartments. There are many exotic species, varying in character and in the colour of their flowers, which is either white, red, or blue.

OAK

N. Lotus, which has white flowers, is the White Lotus of the Nile.

Nymphaeaceæ (Nymphaea, one of the genera). In Botany, a natural order of plants, containing the Water-lilies of various parts of the world; they are polypetalous, polyandrous Exogens, with the sides of the cells of the fruit covered with numerous seeds. Their stems burrow into the mud of the places where they grow, and have slightly astringent narcotic properties. The species are most valued for the beauty of their flowers, which, in *Victoria regia*, are among the largest in nature, measuring as much as four feet in circumference.

Nymphalis. A genus of diurnal Lepidopterous insects, now the type of a family.

Nymphipara (Gr. *νύμφη*, a nymph; Lat. *pario*, I produce). A hybrid name applied by Réaumur to a family of Dipterous insects, and changed by Latreille into *Pupipara*.

Ostagnus (Gr. *ὀστᾶγος*). A winking of the eyes, as observed in a drowsy person.

O

O. A letter of the vowel series, which, if arranged according to the nature of the sound, occupies a position between *a* and *u*. It is susceptible of numerous interchanges. The Greeks had two forms of this letter, *o* (*omicron*, or little *o*), and *ω* (*omega*, or large *o*); the former of which was equivalent to the short, and the latter to the long pronunciation of this letter in other countries. Among the Irish, the letter *O* prefixed to a name is equivalent to *Fitz* in England and *Mac* in Scotland, indicating *son*.

O. In Music, the *O*, or circle, is a note which we call a *semibreve*, the French a *ronde*, and the Italians *circolo*.

Oak (Ger. *eiche*). The general name of a well-known hard-wooded forest tree, much cultivated for the purposes of timber, particularly in shipbuilding, and in other cases when much exposure to the weather is necessary. There are several varieties of this valuable tree (*Quercus Robur*); but the common English Oak, distinguished as *Quercus pedunculata*, claims precedence of every other. The oak timber imported from America is very inferior to that of this country: the oak from the central parts of Europe is also inferior, especially in compactness and resistance of cleavage. The knotty oak of England, the 'unwedgeable and gnarled oak,' as Shakespeare calls it, when cut down at a proper age (from fifty to seventy years), is the best timber known. Some kinds are harder, some more difficult to rend, and some less capable of being broken across; but none possesses all the three qualities in so great or in such equal proportions; and thus, for at once supporting a weight, resisting a strain, and not splintering by a cannon shot,

the timber of the oak may be regarded as superior to every other.

A fine Oak is one of the most picturesque of trees: it conveys to the mind associations of strength and duration which are very impressive. The oak stands up against the blast, and does not take, like other trees, a twisted form from the action of the winds. Except the cedar of Lebanon, no tree is so remarkable for the stoutness of its limbs; they do not exactly spring from the trunk, but divide from it; and thus it is sometimes difficult to know which is stem and which is branch. The twisting of the branches of the oak, too, adds greatly to its beauty; and the horizontal direction of its boughs, spreading over a large surface, completes the idea of its sovereignty over all the trees of the forest.

The oak is raised from acorns, sown either where the oak is to stand, or in a nursery whence the young trees are transplanted.

The colour of oak wood is a fine brown, and is familiar to every one: it is of different shades; that inclined to red is an inferior kind of wood. The larger transverse septa are in general very distinct, producing beautiful figures when cut obliquely. Where the septa are small, and not very distinct, the wood is much the strongest. The texture is alternately compact and porous; the compact part of the annual ring being of the darkest colour, and in irregular dots, surrounded by open pores, producing beautiful dark veins in some kinds, particularly in pollard oaks. Oak timber has a peculiar odour, and the taste is slightly astringent. It contains tannic and gallic acid, and is blackened by contact with iron. The young wood of English oak is very tough,

OAK APPLE

often cross-grained, and difficult to work. Foreign wood, and that of old trees, is more brittle and workable. Oak warps and twists much in drying, and shrinks in seasoning.

Oak of good quality is perhaps more durable than any other wood that attains a like size. Vitruvius says it is of eternal duration when driven into the earth: it is extremely durable in water; and in a dry state it has been known to last 1,000 years. The more compact it is, and the smaller the pores are, the longer it will last; but the open, porous, and foxy-coloured oak, which grows in Lincolnshire and some other places, is not nearly so durable.

The sessile-fruited Oak (*Quercus sessiliflora*), often included with *Quercus pedunculata* under the name of *Quercus Robur*, is pretty abundant in several parts of England, particularly in the north. The wood of this oak is said by Tredgold to be darker, heavier, harder, and more elastic than the common oak; tough, and difficult to work; and very subject to warp and split in seasoning. Mr. Tredgold seems disposed to regard this as superior to the common oak for shipbuilding; but other high authorities are opposed to him on this point. A well-informed writer in the *Quarterly Review*, indeed, remarks that *Quercus Robur* affords a close-grained, firm, solid timber, rarely subject to rot; while that of the *Quercus sessiliflora* is more loose and sappy, very liable to rot, and not half so durable. It may thus be discriminated from the true old English oak: The acorn stalks of the *Robur* are long, and its leaves short; whereas the *sessiliflora* has the acorn stalks short, and the leaves long: the acorns of the former grow singly, or seldom two on the same footstalk; those of the latter in clusters of two or three close to the stem of the branch. We believe that those Russian ships of the Baltic which are not of larch or fir are built of this species of oak; but if this were not the case, their exposure on the stocks, without cover, to the heat of summer (which, though short, is excessive), and the rifts and chinks which are filled up with ice and snow in the long winter, are enough to destroy the stoutest oak, and sufficiently account for their short duration. On the whole, it may be concluded that the durability of oak timber depends more on the nature of the soil, and on the rapidity or slowness of growth, than on the particular variety of which it is the produce.

Oak Apple. A species of gall-nut produced upon oak trees: it is usually spheroidal, and from one to two inches in diameter: its texture is spongy, and it is sometimes employed as a substitute for nut-gall in dyeing.

Oak Leather. A kind of fungus-spawn, found in old oaks, having, when removed, somewhat the appearance of white kid leather. It is sometimes used for spreading plasters on.

Oakum. The fibres of old hempen rope: it is used on shipboard in caulking seams &c. in combination with pitch.

Oannes. In Ancient Mythology, a Babylonian divinity, identified by some with the

OASIS

god Dagon, like whom he had with a human head the body of a fish. But the myth that this monstrous being conversed with men by day, and plunged into the sea by night, suggests a parallel with that of Proteus. In his universal instructions, which embrace the principles of all science, he is the counterpart of the Chinese Fohi and the Egyptian Thoth, or Hermes Trismegistus.

Oar (Norse *ar*, Esthon. *air*. The root of this word is *AR*, to plough. Thus Shakespeare speaks of *earing* [i.e. ploughing] the sea with keels. The root is found in the Greek *ἀρός*, to plough, and *ἀρώω*, to row, *ἀρσεν*, a plough, *ἀρσεν*, Lat. *remus*, an oar). In Nautical Affairs, a long piece of timber, flat at one end, and round or square at the other, by which a boat, barge, or galley, &c. is propelled through the water. The flat part dipped into the water is called the *blade*; the other end is the *loom*, which terminates in the handle. The fulcrum of the oar is the water, at the point of the blade, into which it is dipped, and the resistance offered by the weight of the boat is applied at the gunwale, where the oar is supported by means of the rowlock. The power is the rower's strength acting on the handle and within the boat. The oar is consequently a lever of the second class.

Oar-wood. The large form of *Laminaria digitata*.

Oasis (derived from the Coptic *ouah*, Arab. *wāh*). The name given to those fertile spots, watered by springs and covered with verdure, which are scattered about the great sandy deserts of Africa. The most noted are situated in the Libyan desert. The oases of Egypt are nothing more than valleys or depressions of the plain which forms the table-land of Eastern Africa. They resemble, in many respects, a portion of the valley of Egypt, being surrounded by steep cliffs of limestone at some distance from the cultivated land, varying in height in the different oases, those rising from the southern oases being the highest, and all of them being intersected by patches of desert. They owe their origin doubtless to the springs with which they abound, the decay of the vegetation thence arising having produced the soil with which they are now covered. Their fertility has been celebrated; but the eulogiums of travellers on their beauty are in a great measure to be ascribed to the contrast with the deserts by which they are surrounded. It may appear strange that they should have been selected as places of banishment; but that such was the case, at least under the Romans, is certain. A law of the *Digest*, lib. xlviii. tit. 22, refers to this practice; and it has been supposed that the poet Juvenal was one of those who suffered a temporary banishment (*relegatio*) to the oases, though the evidence of this is by no means clear. (*Biographie Universelle*, art. 'Juvenal.'). The larger oases have some fine ruins, the most celebrated of which is the temple of *Ammō*, at *Sivah*. [DESMER.]

OAST

Oast (Dutch *ast*, a *klin*). The term applied to a kiln for drying hops, heated by a stove with flues.

Oast House. [HOR OAST.]

Oat (A.-Sax. *ata*, akin to *set*, *food*). The common name of one of the corn-producing grasses commonly cultivated in temperate climates. [AVERN.] The seeds of one species of Oat, *A. sterilis*, have remarkably long hygroscopic awns, by means of which they move forwards, as the awns become expanded or contracted by the influence of drought or moisture. They are hence called *animal oats*.

The Common Oat is *Avena sativa*, of which many varieties are grown. The grain is used for feeding horses; and when ground into a coarse meal, forms a considerable proportion of the food of labouring men in Scotland, Ireland, and the north of England. The grain coarsely broken after the removal of the husk forms grits, an article extensively used in making gruel or invalids' food; and the chaff is made into beds by the poor, and forms a good and wholesome substitute for feathers, and one which is readily renewed.

Oath (A.-Sax. *ath*). An oath is defined by Paley 'the calling on God to witness, i.e. take notice of what we say; and invoking His vengeance, or renouncing His favour, if what we say be false, or if what we promise be not performed.' By the jurisprudence of nearly all known nations it has been admitted, in one form or another, as the solemn test of truth in judicial proceedings. Thus, as a general rule, all evidence in such proceedings must be given on oath by English law; and the having taken such oath subjects the witness to the penalties of perjury if his testimony be false. As to the exceptions to this rule, see EVIDENCE; WITNESS.

Oaths are still required by law on many occasions besides the giving evidence in judicial proceedings, and were formerly required still more frequently until the 5 & 6 Wm. IV. c. 62, which substituted solemn declarations in a great variety of cases, especially relating to the customs, excise, and post-office, and declared the making of such a declaration falsely to be a misdemeanour. Besides the Quakers and Moravians, several small sects of Christians profess conscientious objections to oaths, grounded on the express language of the Scriptures. The church of England, in common with the Catholic church in all ages, and with most varieties of Christians, considers judicial oaths lawful, and declares them so by her thirty-ninth article. They have been held mischievous or unnecessary by some philosophical writers, especially Bentham, in his *Rationale of Evidence*. The only answer to his arguments appears to be, that however unreasonable the belief that the duty of truth is rendered more imperative by the formality of an oath, still, while such a belief is prevalent, or while the imagination of witnesses in general is impressed by its solemnity, the convenience of retaining the practice overbalances the disadvantages.

OBELISK

Oatmeal. The grain of the Oat bruised or ground into a coarse meal. This meal, when stirred into boiling water with a little salt until it becomes of a pasty consistence, forms porridge, which, eaten with milk or treacle, forms a palatable food for persons who take good exercise. When made into dough with water, and baked into cakes on an iron plate, it forms bannocks or oat-cakes, the use of which was once almost universal in Scotland, the *land of cakes*. In Germany, coarse oatmeal, baked brown and then called *habermehl*, is used in broths and pottages, as the semolina made from wheat is used in France and Italy.

Obeccurate (Lat. *ob*, *inversely*; *cordatus*, *heart-shaped*). In Botany, a term applied to bodies which are inversely heart-shaped, i.e. with the broad end forming the apex.

Obeah. A name applied to certain superstitious usages among the negro tribes of the western part of Africa, an Obea-man or Obea-woman being one who practises Obi. Our knowledge of these superstitions is derived not from African travellers, but from observation of negroes transplanted by the slave trade to the West Indies. The practitioners in the time of Bryan Edwards, who has described this sorcery in his *History of the West Indies*, were always persons born in Africa. They were consulted in cases of sickness or other emergency, and sold charms or spells. [FETTERED.] A considerable knowledge of the art of poisoning was part of their accomplishments. A law was passed in Jamaica expressly for the suppression of this practice, which has been said, nevertheless, to subsist to some extent even in the present day. The system has assumed forms with which the history of witchcraft makes us familiar in almost all countries, one function of the Obea-women of the West Indies being to procure the death of a person whose waxen image is under their hands wasting away. But that the superstition is founded on the notion of a material connection between living beings or between living and inanimate things, seems to be proved by the singular custom of the Couvade (practised not only among negroes, but in America, and in the Basque country), which compels the husband to take to his bed when the wife bears a child, lest harm happening to him should extend to the infant also. (E. B. Tylor, 'Researches into the History of Mankind,' *Edin. Rev.* April 1864, p. 388.)

Obedience, Passive. In Politics, this term signifies the unqualified obedience which, according to some political philosophers, is due from subjects to the supreme power in the state. [NON-RESISTANCE.]

Obelisk (Gr. *obeliskos*). A lofty quadrangular monolithic column, diminishing upwards, with the sides gently inclined, but not so as to terminate in an apex at the top, the sides being sloped off so as to form a flatish pyramidal figure, by which the whole is suitably finished off and brought to a point, without the upper

OBELISK

part being so contracted as to appear insignificant. Egypt was, properly speaking, the land of obelisks; and they are probably to be reckoned among the most ancient monuments of that extraordinary people. It has been frequently asserted that obelisks were originally erected in honour of the sun, of which they were said to be symbolical, and that they served the purposes of a gnome or sundial; but the more common opinion is that obelisks were nothing more than monumental structures, serving as ornaments to the open squares in which they were generally built, or intended to celebrate some important event and to perpetuate its remembrance. They were usually adorned with hieroglyphics; and we learn from Diodorus and Strabo that the inscriptions with which they were charged declared the amount of gold and silver, the number of troops, and the quantity of ivory, perfumes, and corn which all the countries subject to Egypt were required to furnish. The two largest obelisks were erected by Sesostris in Heliopolis. They were formed of a single block of granite, and measured 180 feet in height. When Egypt became a Roman province, Augustus removed these obelisks to his own capital; and this practice found imitators both in some of his successors to the imperial throne, and, at a much later period, in many of the Roman pontiffs from the sixteenth century down to the present times. Of these obelisks, that of the Lateran, which is the largest now known, being 106 feet in height exclusive of the pedestal, and weighing 440 tons, was brought by Constantine from Heliopolis to Alexandria, and thence by Constantine, his son, to Rome, where it was erected in the Circus Maximus. The obelisk next in size to that of the Lateran was placed originally in the Vatican circus by Caligula, but it now stands in the piazza of St. Peter's; its entire height is 133 feet, including the pedestal, &c. The obelisks most generally known, at least in name, are the Luxor (removed to Paris in 1833) and the two monoliths called Cleopatra's Needles, of which one is standing and the other on the ground. Of these, the Luxor obelisk is 76 feet in height, while the Needle of Cleopatra which still stands is about 63 feet in height, exclusive of the pedestal, &c. (See the learned treatise of Zoega on Obelisks, and Sir G. Wilkinson's *Egyptians*, vol. iii. *passim*, which contains some excellent illustrations of the different methods adopted by that people for removing their huge structures from place to place.)

Obelus. In Printing, a dagger, marked thus †, used as a reference to notes in the margin or at the bottom of the page.

Obelus. In Diplomatics, a mark so called from its resemblance to a needle (Gr. ὀβελός); usually thus — or thus + in ancient MSS. It was used by Origen, in his *Hexapla*, to mark the passages where something is found in the Septuagint which is not in the Hebrew. The common use of the line — in modern writing is to mark the place of a break in the sense,

OBITUARY

where it is suspended, or where there is an ungrammatical transition; but a paragraph introduced where the sense is suspended is marked by the sign of a

Oboron. In Mediæval Mythology, the 1 of the fairies. Wieland's beautiful poem, Weber's romantic opera of this name, the *Midsommer Night's Dream*, and innumerable other poems and tales of which he is the hero, have made the name of Oboron so familiar, that it will be unnecessary to do more in this place than to state the origin of the fable. The name Oboron first appears in the old French *fabliaux* of Huon of Bordeaux; it is identical with Auberon, or Alberon, the first syllable of which is nothing more than the old German word Alb, *elf* or *fairy*, which in the *Heldenbuch* and other old German poems is expressed variously by Alberich or Alban. (Grimm's *Deutsche Mythologie*, p. 256.) His wife's name was Titania, or Mab, whose powers have been so beautifully depicted in *Romeo and Juliet*.

Obesity (Lat. *obesitas*). This condition, to which the name of *polyæmia* (Gr. πολυæμία) has been given, is brought about by the deposit of an excessive amount of fat in the areolar tissue or subcutaneous network of cells. This excessive secretion of fatty matter is often the result of indolence, and excessive indulgence in farinaceous and saccharine foods and drinks. It would seem also that a tendency to obesity is hereditary in some cases; and in such cases it results in all probability from the peculiarity of the organism which is associated with the

between the lung capacity as 1 the processes. Many remarkable

are recorded of immense obesity; thus, a girl is spoken of in the *Philosophical Transactions* for 1813, who at four years of age weighed 266 lbs. Bright, of Maldon, and Daniel Lambert were both extraordinary instances of obesity, and weighed respectively 728 lbs. and 789 lbs. Much has been written on the best method of preventing and removing obesity; all, however, insist on the great principle of avoiding farinaceous, oily, and saccharine ingesta in every form; and when discretion is used, great advantage sometimes accrues from this plan to the patient. But, on the other hand, much evil may arise from the adoption of a disciplinary diet unwatched by a physiological observer; and this especially applies to the rapid reduction of obesity in those who are hereditarily predisposed to it.

Obit. [OBITUARY.]

Obit (Lat. *obitus*, *death*). In the Roman Catholic ritual, a service performed for the repose of a departed soul.

Obituary. In the Roman Catholic Church, a register in which are enrolled the names of deceased persons for whom obits are to be performed, and the days of their funeral. It is also used for the book containing the foundation or institution of the several obits in a church or monastery. In the former sense it

OBJECT

is synonymous with *neurology*, in the latter with *martirology*.

Object, Objective. In Philosophy, opposed to *subjective*. [SUBJECT, SUBJECTIVE.]

Object-glass of a Refracting Telescope or Microscope. The lens which first receives the rays of light coming directly from the object, and collects them into a focus, where they form an image which is viewed through the eye-glass.

The excellence of an object-glass depends on the distinctness of the image which it forms. On account of the unequal refrangibility of the rays of light, it is necessary, in order to procure a distinct image, to employ an achromatic combination of lenses, formed of substances having different dispersive powers, and of such figures that the chromatic and spherical aberrations of the one may be corrected by that of the other. The substances used are crown glass and flint glass; the dispersive powers of which are respectively as 3 to 5. By combining a convex lens of crown glass with a concave lens of flint glass, having their focal distances in that proportion, an image would be formed free from colour, but it would not be free from spherical aberration. The determination of the form of the compound lens which shall give the least possible spherical aberration for parallel rays is a problem which admits of exact calculation. The following are the dimensions found by Sir John Herschel for a telescopic object-glass of thirty inches focal length, of the form shown in the annexed figure, where A B is the convex lens of crown glass on the outside towards the object, and C D the concave lens of flint glass placed on the inside towards the eye: radius of the exterior surface *a* of the crown lens, 20·0364 inches; radius of the exterior surface *b* of the flint lens, 41·1687 inches; radii of the interior surfaces *c*, 10·1604 and 10·1613 inches. (*Ency. Metr.* art. 'Light,' § 471.) When the lenses have the forms here indicated, the focal lengths of each, separately, are in the direct ratio of their dispersive powers; and the two inside surfaces have so nearly the same curvature, that they may be ground on the same tool, and united by a cement to prevent the loss of light at the two surfaces. Such is one of the forms indicated by theory, but it is not the one now generally adopted; other forms are due to Fraunhofer, Gauss, &c.

It is well known, that for every lens, whether convex or concave, there is a form of minimum aberration for any given pencil of light; consequently, on either side, so to speak, of the minimum, there is a lens of one form having the same amount of aberration as a lens of another form on the other side of the minimum; that is to say, there are always two lenses of two different forms which have the same amount of spherical aberration for the same material, aperture, and focal length.

Suppose, then, a convex lens, A, of the Herschelian or Fraunhofer form is rendered aplanatic by a concave flint lens, B. Then A is double

OBJECT-GLASS

convex, having its exterior surfaces more curved than its posterior. Again, in Herschel's and

Fraunhofer's forms, the flint lens B is a concavo-convex lens, the anterior face being more curved than the posterior; there is, therefore, another lens, D, on the other side of the minimum aberration form, having for the same aperture and powers the same aberration as B, but convexo-concave, with its posterior or concave face much more deeply curved than the anterior.

These two lenses, C and D, produce the combination proposed by Gauss, and recently adopted by Steinheil. Their coexistence is rendered necessary by the existence of the other or Herschelian form. (*Rev. C. Pritchard in Monthly Notices R.A.S.* vol. xxv. p. 27.) The early telescopes, with a view of avoiding the chromatic aberration resulting from the employment of object-glasses of short focus, were constructed with focal lengths of enormous dimensions—500 feet in some cases. Till within the last few years, the difficulty of making glass of sufficient purity proved a great obstacle to the construction of object-glasses of large aperture. The difficulty was first obviated in Germany, and since that time in England, especially by Chance of Birmingham; and an object-glass of the astounding size of twenty-five inches aperture, the glass of which was made by him, is in process of mounting by Messrs. Cooke and Sons, of York.

The process of grinding a large object-glass, as conducted by that firm, is one of the greatest possible interest. Steam is the motive power employed by them, and, naturally, the years formerly required for the production of a lens of considerable size, say eight to ten inches, have been reduced to months. The density of the glass is first determined; and when this is known, the curves of the lenses are mathematically calculated. 'Tools' are then prepared of the various curvatures required, and after rough grinding the discs are applied to them, the tools being covered with a polishing surface supplied with dry emery. The perfection of the object-glass depends greatly upon the combination of motions given to the polisher. When the lenses are polished, the process of centring, by which the centres of all the curves are made to fall in the same straight line, is accomplished, and the object-glass is placed in a cell and tested for the two aberrations; the chromatic aberration being corrected by altering the curvature of that surface which least affects the spherical aberration.

The Northumberland object-glass at the Cambridge Observatory, by Cauchoix of Paris, is of eleven and a half inches effective aperture; but the largest in use at the present time are

OBJECTIVE CASE

those of the great telescopes belonging to the observatory of Chicago (of 18½ inches aperture), to the central observatory at Pulkova in Russia, and to the observatory at Cambridge in the United States, the extreme diameter being fifteen and a half inches, and the effective aperture about fifteen inches in both cases. The latter are the workmanship of Merz and Mahler, of Munich. [ACHROMATISM; LENS; TELESCOPE.]

For microscopic object-glasses the same processes are in the main adopted, but the combination is more complicated, and extreme difficulty is induced by the small size of the lenses themselves. In the 8th object-glass recently completed by Messrs. Powell and Lealand, the object-glass is itself almost a microscopic object. [MICROSCOPE.]

Objective Case. In Grammar. The case commonly known as the ACCUSATIVE.

Oblate (Lat. *oblatus*, *offered*). In Ecclesiastical Antiquities: 1. A person who, on embracing the monastic state, had made a donation of all his goods to the community. 2. One dedicated to a religious order by his parents from an early period of his life. 3. A layman residing as an inmate in a regular community, to which he had assigned his property either in perpetuity or for the period of his residence. 4. A layman who had made donation, not only of his property, but his person, as bondsman to a monastic community. In France the king possessed, in ancient times, a privilege of recommending a certain number of *oblats*, chiefly invalided soldiers, to monasteries, whom they were bound to maintain.

Oblate Spheroid. [SPHEROID.]

Oblation (Lat. *oblatio*, *an offering*). This word means, properly, an offering presented to the church. This practice commenced at an early period in the history of the church, for originally the Christian priesthood had no other maintenance or allowance than the free gifts or oblations of the people. This is commonly thought to be the meaning of the word in the phrase *alms and oblations* in the Anglican Communion Service; though it is held by some to refer to the elements of the bread and wine.

Obligation (*obligatio*, from Lat. *obligo*, *I bind*). In the most general sense, a duty imposed by law, to the fulfilment of which one party is bound towards another. Obligations, according to the civil law, are said to arise in four ways; out of contracts, quasi-contracts, delicts, or quasi-delicts. A principal obligation is that by which a debtor is bound to his creditor; an accessory obligation, that by which one is bound to another to satisfy the contract of a third party. The Roman juriconsults divided obligations into natural, civil, and mixed, and also into civil and pretorian. In English legal phraseology the word *obligation* is used as a technical term for a bond with penalty and condition. He who enters into an obligation is styled *obligor*; he towards whom it is entered into, *obligee*.

OBROK

Obligato (Ital.). In Music, a term applied to a part in a composition for a particular instrument, which cannot be dispensed with.

Oblique (Lat. *obliquus*). Not perpendicular. Thus, in Geometry, an oblique section of a cylinder is one whose plane is not perpendicular to the axis. Again, a right line drawn from a given point to a given right line, and not perpendicular to the latter, is called an *oblique*. [DEPARTURE.]

Oblique Motion. In Contrapuntal Music, that motion in which one of the parts holds on a sound, whilst the other rises or falls.

Obliquity of the Meliptic. In Astronomy, the inclination of the plane of the earth's equator to the plane of the ecliptic, or the angle formed by those two planes, on which the phenomena of the seasons depend. [ECLIPSE.]

Oblong (Lat. *oblongus*). In Botany, a term applied to bodies which are elliptical and blunt at each end, as in the leaves of *Hypericum perforatum*.

Oblong. In Geometry, a parallelogram which is equiangular but not equilateral. The term is synonymous with *rectangle*. A prolate spheroid is sometimes, though rarely, called an *oblong spheroid*.

Oboe (Ital.). A musical wind instrument, sounded through a reed. It is shaped somewhat like a clarinet, being slender in the upper part but spreading out conically at the bottom, and consists of three joints or pieces, besides the reed. Its compass is generally two octaves and a fifth, from C, below the treble clef, to G, the fourth line above the staff. The ancient name of oboe was *waght*, which is still visible in the modern word *Watts*; and in this form the oboe was in use as far back as the reign of Edward III. It is only since the beginning of the present century that the Italian form of this word came into general use; previously to that period the French name, *hautbois*, was universally current.

Obolus (Gr. *ὀβολός*). An Athenian silver coin of very small dimensions; being only equal in value to about 1½d. of our money, or less according to some computations. Seven of them were equal to an Attic drachma.

Obovate (Lat. *ob*; *ovatus*, *egg-shaped*). In Botany, inversely ovate.

Obovoid. In Botany, a term applied to bodies which approach the obovate form.

Obrine. The name of a military order, instituted in the thirteenth century by Conrad, duke of Mazovia in Poland; styled also the Order of Jesus Christ. It was instituted to levy war against the Russians.

Obrok. A Russian word signifying *tax*. It is used in two senses, one for a rent, the other for the poll tax paid by peasants, who, being dependants on lords, have either been sent from the lords' domains to learn some manufacture, or have voluntarily quitted the locality of their birth or place of feudal dependence. This tax on the town peasants varied, according to Baron Haxthausen, from twenty to four hundred roubles of annual payment, i. e. from
